#### ABSTRACT

The all-Galaxy CO survey of Dame et al. is by far the most uniform, large-scale Galactic CO survey. Using a dendrogram-based decomposition of this survey, we present a catalog of 1064 massive molecular clouds throughout the Galactic plane. This catalog contains  $2.5 \times 10^8$  solar masses, or  $25^{+10.7}_{-5.8}\%$  of the Milky Way's estimated  $H_2$  mass. We track clouds in some spiral arms through multiple quasiants. The power index of Larson's first law, the size-linewidth relation, is consistent with 0.5 in all regions—possibly due to an observational bias—but clouds in the inner Galaxy systematically have significantly ( $\sim 30\%$ ) higher linewidths at a given size, indicating that their linewidths are set in part by the Galactic environment. The mass functions of clouds in the inner Galaxy versus the outer Galaxy are both qualitatively and quantitatively distinct. The inner Galaxy mass spectrum is best described by a truncated power law with a power index of  $\gamma = -1.6 \pm 0.1$  and an upper truncation mass of  $M_0 = (1.0 \pm 0.2) \times 10^7 M_{\odot}$ , while the outer Galaxy mass spectrum is better described by a non-truncating power law with  $\gamma = -2.2 \pm 0.1$  and an upper mass of  $M_0 = (1.5 \pm 0.5) \times 10^6 M_{\odot}$ , indicating that the inner Galaxy is able to form and host substantially more massive GMCs than the outer Galaxy. Additionally, we have simulated how the Milky Way would appear in CO from extragalactic perspectives, for comparison with CO maps of other galaxies.

Key words: Galaxy: general - ISM: clouds - ISM: molecules

Supporting material: machine-readable table

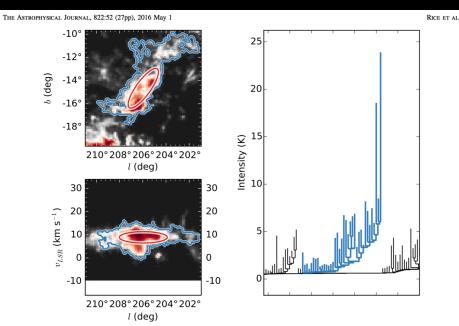

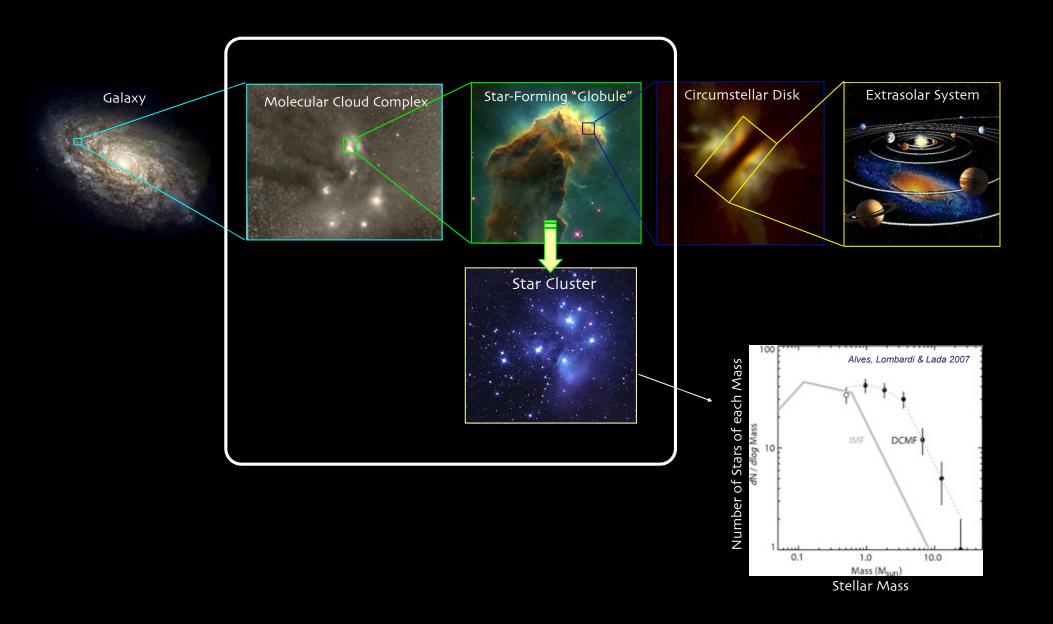

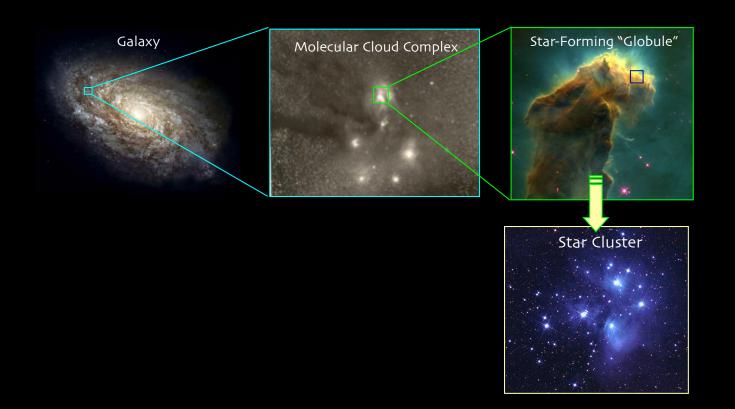

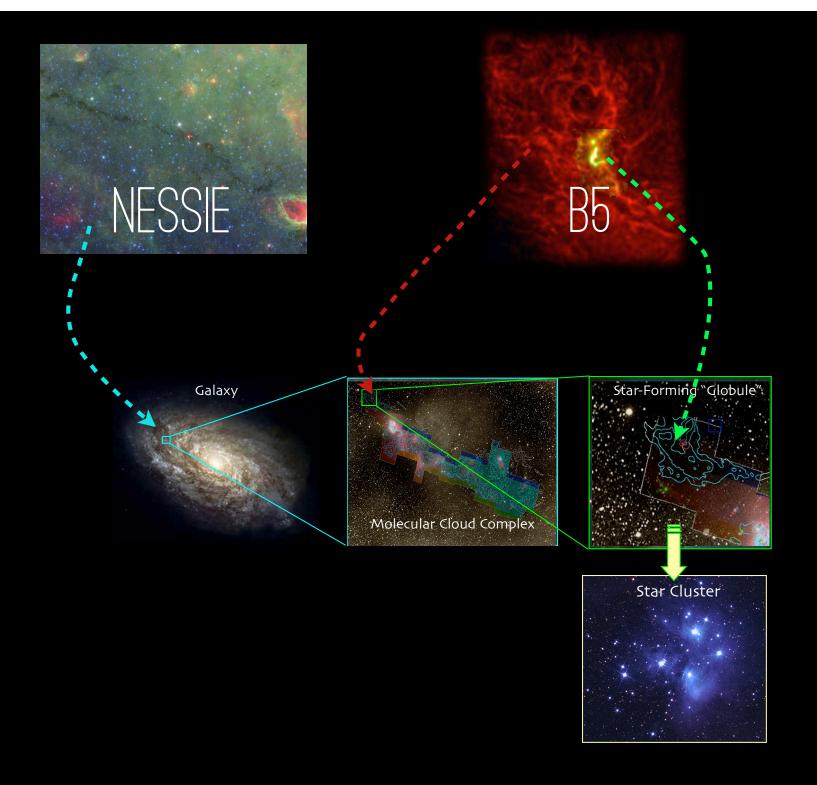

Figure 2. Example dendrogram extraction of Orion B: a nearby, well-studied giant molecular cloud. Top left: (l, b) thumbnail of the cloud and its neighboring region as seen on the sky. Bottom left: (l, v) thumbnail of the same region. Right: dendrogram cutout, with Orion B's structures highlighted in blue. The pixels corresponding to the highlighted dendrogram structures are outlined in the blue contour (in projection); a representative ellipse is drawn in red, with semimajor axis length equal to the second moment along each relevant dimension (as calculated in Section 2.2). Data come from DHT Survey #27 (the Orion complex).

### ARE SOME PLACES SPECIAL?

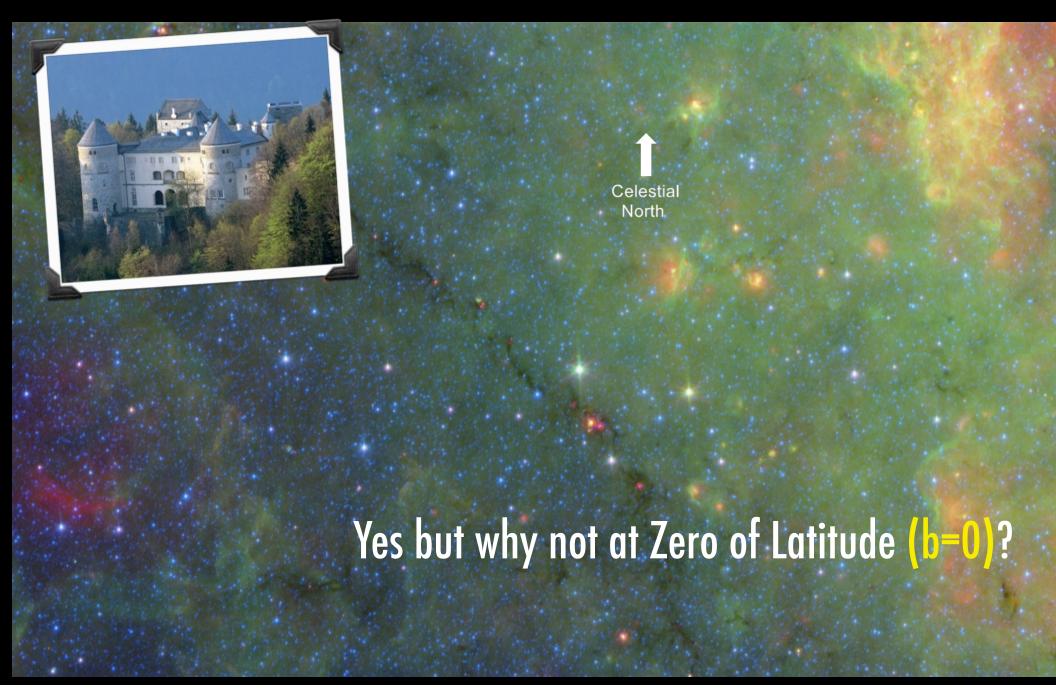

What are "special" places in ISM & how long do they last? How do "influences" change what is special?

The mid-plane of a spiral galaxy is a special place.

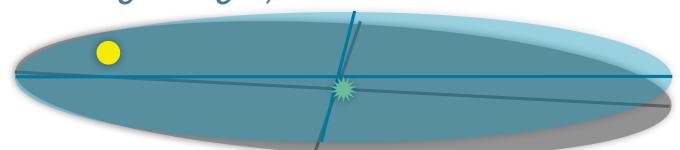

### "Is Nessie Parallel to the Galactic Plane?" -A. Burkert, 2012

### Where are we, really?

"IAU Milky Way", est. 1959

True Milky Way, modern

The equatorial plane of the new co-ordinate system must of necessity pass through the sun. It is a fortunate circumstance that, within the observational uncertainty, both the sun and Sagittarius A lie in the mean plane of the Galaxy as determined from the hydrogen observations. If the sun had not been so placed, points in the mean plane would not lie on the galactic equator.

[Blaquw et al. 1959]

global spiral potential of the Galaxy.

### And it may have friends!

Milky Way Bones: Ultra-dense, high aspect ratio Nessie analogs that may form the "Skeleton" of the Milky Way. Analogs must satisfy quantitative Bone criteria (Zucker+2015)

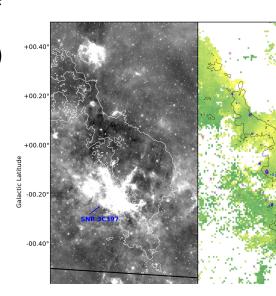

2.3. Establishing "Bone" Criteria

After narrowing down our list to 10 filaments with kinematic structure consistent with existing spiral arm models, we develop a set of criteria for an object to be called a "bone":

- 1. Largely continuous mid-infrared extinction feature
- 2. Parallel to the Galactic plane, to within 30°
- 3. Within 20 pc of the physical Galactic mid-plane, assuming a flat galaxy
- 4. Within 10 km s<sup>-1</sup> of the global-log spiral fit to any Milky Way arm

# COHERENT CORES ISLANDS OF CALM IN TURBULENT SEAS(?)

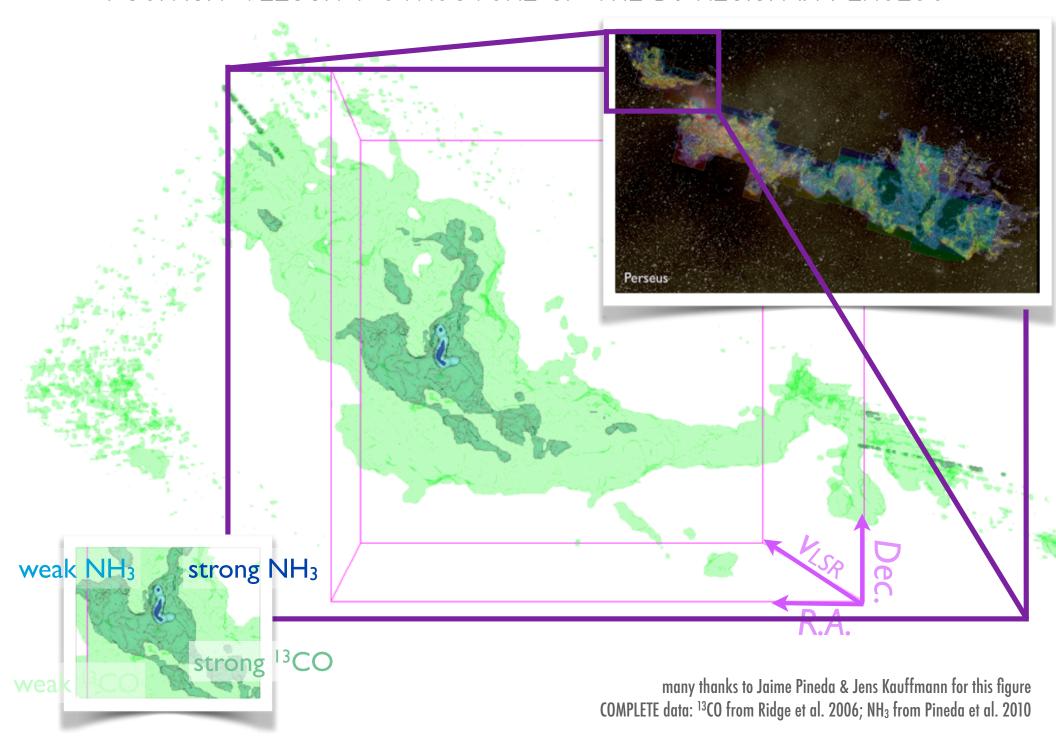

The 30-year story: Myers & Benson 1983, Goodman et al. 1998, Pineda et al. 2010, 2011, 2014

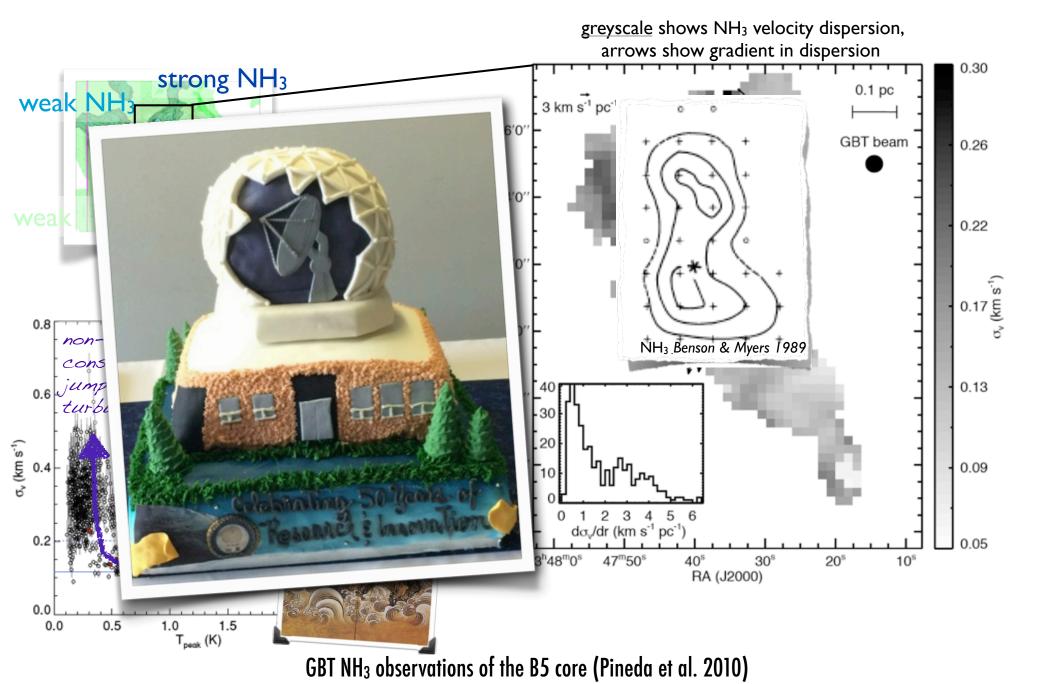

THE ASTROPHYSICAL JOURNAL, 504:223-246, 1998 September 1 © 1998. The American Astronomical Society. All rights reserved. Printed in U.S.A. COHERENCE IN DENSE CORES. II. THE TRANSITION TO COHERENCE ALYSSA A. GOODMAN1 Harvard University Department of Astronomy, Cambridge, MA 02138; agoodman@cfa.harvard.edu JOSEPH A. BARRANCO Astronomy Department, University of California, Berkeley, Berkeley, CA 94720; barranco@ucbast.berkeley.edu DAVID J. WILNER Harvard-Smithsonian Center for Astrophysics, 60 Garden Street, Cambridge, MA 02138; dwilner@cfa.harvard.edu MARK H. HEYER Five College Radio Astronomy Observatory, University of Massachusetts, Amherst, MA 01003; heyer@fcrao1.phast.umass.edu "Chaff" Received 1997 June 17; accepted 1998 February 5 ABSTRACT After studying how line width depends on spatial scale in low-mass star-forming regions, we propose that "dense cores" (Myers & Benson 1983) represent an inner scale of a self-similar process that characterizes larger scale molecular clouds. "Coherent Core" 0.01 to 10 pc scales

Fig. 10.—An illustration of the transition to coherence. Color and shading schematically represent velocity and density in this figure. On large scales, material (labeled chaff) is distributed in a self-similar fashion, and its filling factor is low. On scales smaller than some fiducial radius, the filling factor of gas increases substantially, and a coherent dense core, which is not self-similar, is formed. Due to limitations in the authors' drawing ability, the figure emphasizes a particular size scale in the chaff, which should actually exhibit self-similar structure on all scales ranging from the size of an entire molecular cloud complex down to a coherent core.

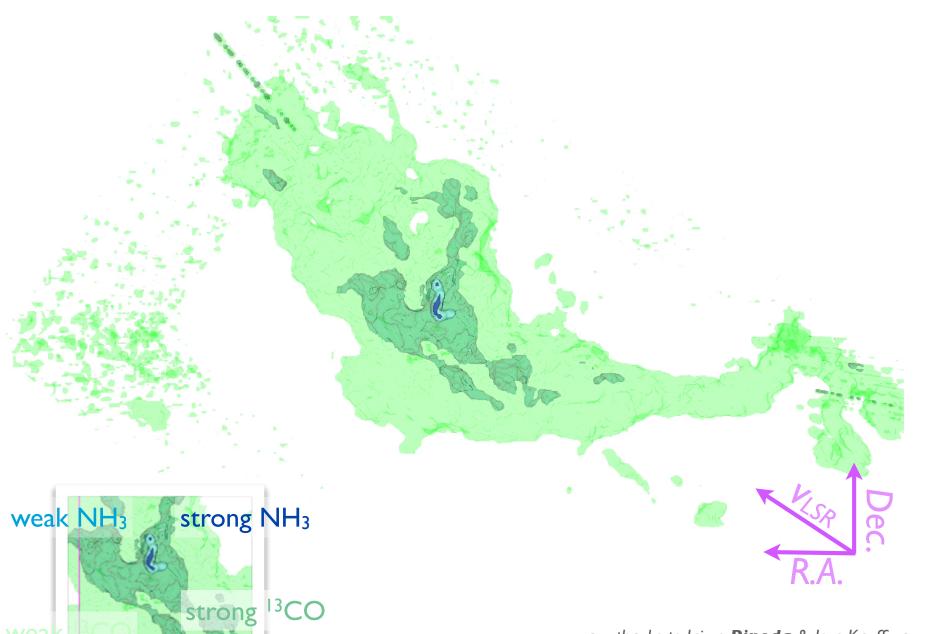

#### POSITION-VELOCITY STRUCTURE OF THE B5 REGION IN PERSEUS

#### STRONG EVIDENCE FOR "VELOCITY COHERENCE" IN DENSE CORES

#### POSITION-VELOCITY STRUCTURE OF THE B5 REGION IN PERSEUS
