The MIN_TO_MAJ_RATIO value specifies the length of the minor axis as a fraction of the major axis length. For a circle, this value is 1.0.

The START_ANGLE and END_ANGLE values select the portion of the curve to be drawn. If they are equal, the entire circle or ellipse is drawn.

Structure IDL_DXF_POLYGON

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
COLOR	Integer
EXTRUSION	Double [3]
FIT_TYPE	Integer
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-7: Fields of the IDL_DXF_POLYGON Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polygons (see the POLYGONS keyword for IDLgrPolygon::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

Note

If a connectivity array is not supplied and the MESH_DIMS are left at 0,0, then IDL will tessellate the vertex list and store the polygon with the resulting connectivity list. If tessellation fails, IDL will throw an error that should be detected and dealt with using the CATCH mechanism. An alternative to this is to pass the polygon to the IDLgrTessellator object, which returns a zero instead of throwing an error if tessellation fails. The results of a successful tessellation can be put into a DXF

entity and passed to the IDLffDXF object, which will not attempt to tessellate the polygon as it has already been tessellated.

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polygon assumes.

Structure IDL_DXF_POLYLINE

Field	Data Type
VERTICES	Pointer (to an array of 3-D points)
CONNECTIVITY	Pointer (to an array of integers)
VERTEX_COLORS	Pointer (to an array of integers)
COLOR	Integer
MESH_DIMS	Integer [2]
CLOSED	Integer [2]
THICKNESS	Double
LINESTYLE	Integer [2]
EXTRUSION	Double [3]
FIT_TYPE	String
CURVE_FIT	Integer
SPLINE_FIT	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-8: Fields of the IDL_DXF_POLYLINE Structure

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polylines (see the POLYLINES keyword for IDLgrPolyline::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polyline assumes.

Structure IDL_DXF_POINT

Field	Data Type
PT0	Double [3]
UCSX_ANGLE	Double
THICKNESS	Double
COLOR	Integer
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-9: Fields of the IDL_DXF_POINT Structure

PT0 is the location of the point in space.

UCSX_ANGLE is an internal DXF orientation parameter used for symbol plotting.

Structure IDL_DXF_SPLINE

Field	Data Type
CTR_PTS	Pointer
FIT_PTS	Pointer
KNOTS	Pointer
WEIGHTS	Pointer
COLOR	Integer
DEGREE	Integer
PERIODIC	Integer
RATIONAL	Integer
PLANAR	Integer
LINEAR	Integer
KNOT_TOLERANCE	Double
CTL_TOLERANCE	Double
FIT_TOLERANCE	Double
START_TANGENT	Double [3]
END_TANGENT	Double [3]
THICKNESS	Double
LINestyle	Integer [2]
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-10: Fields of the IDL_DXF_SPLINE Structure

This structure is returned verbatim from the DXF spline structure without interpretation. It is up to the user to interpret these values.

Structure IDL_DXF_TXT

Field	Data Type
PT0	Double [3]
TEXT_STR	String
COLOR	Integer
HEIGHT	Double
WIDTH_FACTOR	Double
BOX_WIDTH	Double
DIRECTION	Double [3]
ROT_ANGLE	Double
JUSTIFICATION	Integer (0=left, 1=center, 2=right, 3=aligned, 4=middle, 5=fit)
VERTICAL_ALIGN	Integer (0=baseline, 1=bottom, 2=middle, 3=top)
SHAPE_FILE	String
THICKNESS	Double
EXTRUSION	Double [3]
DXF_TYPE	Integer
BLOCK	String
LAYER	String

Table 30-11: Fields of the IDL_DXF_TXT Structure

PT0 is the location of the text string.

TEXT_STR is the actual string.

HEIGHT specifies the overall scaling of the glyphs while WIDTH_FACTOR is a correction in the baseline direction (anisotropic scaling). For multi-line text, BOX_WIDTH determines where the line breaks should be placed (0.0 for single line text).

The text baseline is specified by `DIRECTION` and its rotation about the z-axis is specified by `ROT_ANGLE`. Justification is specified by `JUSTIFICATION` and `VERTICAL_ALIGN`. `SHAPE_FILE` is the name of the glyph file used to image this string. The shape file is NOT read by IDL.

Structure `IDL_DXF_XLINE`

Field	Data Type
<code>PT0</code>	Double [3]
<code>UNIT_VEC</code>	Double [3]
<code>COLOR</code>	Integer
<code>THICKNESS</code>	Double
<code>LINestyle</code>	Integer [2]
<code>EXTRUSION</code>	Double [3]
<code>DXF_TYPE</code>	Integer
<code>BLOCK</code>	String
<code>LAYER</code>	String

Table 30-12: Fields of the `IDL_DXF_XLINE` Structure

`PT0` is the start of a ray or a point on a infinite line in space in the case of an `XLINE` entity.

`UNIT_VEC` determines the direction of the line in space.

Structure IDL_DXF_INSERT

Field	Data Type
SCALE	Double [3]
PT0	Double [3]
ROTATION	Double
INSTANCE_BLOCK	String
NUM_ROW_COL	Integer [2]
DISTANCE_BETWEEN	Double [2]
DXF_TYPE	Integer
BLOCK	String
COLOR	Integer
LAYER	String

Table 30-13: Fields of the IDL_DXF_INSERT Structure

The insert entity allows for the “instancing” of a block in a grid fashion.

INSTANCE_BLOCK is the name of a block to repeat.

The block is scaled by SCALE and rotated about the Z axis by ROTATION. The grid begins at PT0 and contains the number of rows and columns specified by NUM_ROW_COL (Note: 0 rows or columns will always give a single instance of the block).

The spacing of the grid is specified by DISTANCE_BETWEEN.

Structure IDL_DXF_BLOCK

Field	Data Type
PT0	Double [3]
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table 30-14: Fields of the IDL_DXF_BLOCK Structure

This entity specifies a BLOCK. Blocks have a location in space (PT0) [objects in the block are interpreted relative to this point], a name, and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Structure IDL_DXF_LAYER

Field	Data Type
COLOR	Integer
NAME	String
DXF_TYPE	Integer

Table 30-15: Fields of the IDL_DXF_LAYER Structure

This entity specifies a LAYER. Layer is a NAME and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

Examples

This example illustrates the difference between the GetEntity and GetContents methods within the IDLffDXF object method. The GetContents method gives a description of the content of the file read, listing the entity types and the number of occurrences. GetEntity accesses the values returned by GetContents and determines how the entities can be logically combined into common structures for drawing efficiency.

```

PRO view_heart
; Determine path to data file.
heartFile = FILEPATH('heart.dxf', $
    SUBDIRECTORY = ['examples', 'data'])
; Initialize DXF data access object.
oHeart = OBJ_NEW('IDLfDXF')
; Read data within DXF file into access object.
status = oHeart->Read(heartFile)
; Determine what type of entities (and how many of
; each entity) exist in the file.
heartTypes = oHeart->GetContents(COUNT = heartCounts)
PRINT, 'Entity Types: ', heartTypes
PRINT, 'Count of Types: ', heartCounts
; Initialize a model for displaying polygon and polyline
; objects.
oModel = OBJ_NEW('IDLgrModel')
; Obtain the tissue data. The tissue is accessed into
; IDL as a single polygon.
tissue = oHeart->GetEntity(heartTypes[1])
HELP, tissue
HELP, tissue, /STRUCTURE
; Initialize color parameter.
tissueColor = [255, 0, 0]
; Initialize polygon data.
vertices = tissue.vertices
connectivity = tissue.connectivity
; Initialize the polygon object.
oTissue = OBJ_NEW('IDLgrPolygon', $
    *vertices, POLYGONS = *connectivity, $
    COLOR = tissueColor)
; Add the polygon to the model.
oModel->Add, oTissue
; Clean-up all the related pointers.
PTR_FREE, tissue.vertices, tissue.connectivity, $
    tissue.vertex_colors
PTR_FREE, vertices, connectivity
; Display the polylines and the polygon in the XOBJVIEW
; utility.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75
; Clean-up the object references.
OBJ_DESTROY, [oHeart, oModel]
END

```

An XOBJVIEW window with the mesh heart object appears when this program is compiled and run. The following lines are found in the workbench Output Log window.

```

IDL> view_heart
% Compiled module: VIEW_HEART.

```

```

% Compiled module: FILEPATH.
% Loaded DLM: DXF.
Entity Types:           7           10           18           20
Count of Types:        13          1624           1           2

```

The Entity Types (7, 10, 18, and 20) are the GetContents method return values corresponding to the occurrence of DXF ENTITY types found in the object: POLYLINES, FACE3D, BLOCK, and LAYER, respectively. Note there are a total of 1624 FACE3D entity types, but for efficiency and speed IDL logically combines all of the similar entities into a single structure that can be used in an IDLgrPolygon object. This is illustrated by the output resulting from the first Help command in the program as shown below.

```

TISSUE          STRUCT    ==>IDL_DXF_POLYGON Array[1]
** Structure IDL_DXF_POLYGON, 13 tags, length=72:
  EXTRUSION     DOUBLE    Array[3]
  VERTICES      POINTER    <PtrHeapVar3>
  CONNECTIVITY  POINTER    <PtrHeapVar4>
  VERTEX_COLORS  POINTER    <PtrHeapVar5>
  MESH_DIMS     INT        Array[2]
  CLOSED        INT        Array[2]
  COLOR         INT        256
  FIT_TYPE      INT        -1
  CURVE_FIT     INT        0
  SPLINE_FIT    INT        0
  DXF_TYPE      INT        10
  BLOCK         STRING     ''
  LAYER         STRING     '0----'
% Compiled module: XOBJVIEW.
% Compiled module: UNIQ.
% Compiled module: IDENTITY.
% Compiled module: XMANAGER.

```

Note that the tissue is represented as an array of polygons having 1 element. This is evident by the mesh representation of the heart object showing the 1624 individual polygons as a single object.

Version History

5.2	Introduced
-----	------------

IDLffDXF::GetPalette

The IDLffDXF::GetPalette procedure method returns the current color table in the object.

Syntax

Obj->[IDLffDXF::]GetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Returns an array of the red components to the current color table.

Green

Returns an array of the green components to the current color table.

Blue

Returns an array of the blue components to the current color table.

Keywords

None

Version History

5.2	Introduced
-----	------------

IDLffDXF::Init

The IDLffDXF::Init function method initializes the DXF object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Result = OBJ_NEW('IDLffDXF' [, Filename] )
```

or

```
Result = Obj->[IDLffDXF::]Init( [Filename] ) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string optional argument containing the full path and filename of a DXF file to be read as the object is created.

Keywords

None

Version History

5.2	Introduced
-----	------------

IDLffDXF::PutEntity

The IDLffDXF::PutEntity procedure method inserts an entity into the DXF object. The type of the entity is determined from the DXF_TYPE field of the entity structure. If DXF_TYPE is set to 0, the type is implied by the entity structure.

Note

Line3D entity types will be written as Line entities due to the obsolete status of Line3D. Polyline entities will be automatically converted to Lightweight Polylines where applicable.

Syntax

Obj->[IDLffDXF::]PutEntity, *Data*

Arguments

Data

An array of Entity structures as defined by the GetEntity method.

Note

If the entity references a non-existent block or layer, one will automatically be created. Blocks and layers can also be created by passing IDL_DXF_BLOCK or IDL_DXF_LAYER structures to this routine.

Keywords

None

Version History

5.2	Introduced
-----	------------

IDLffDXF::Read

The IDLffDXF::Read function method reads a file, parsing the DXF object information contained in the file, and inserts it into itself.

Syntax

Result = *Obj*->[IDLffDXF::]Read(*Filename*)

Return Value

Returns a 1 indicating success in reading the file, otherwise 0.

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be read.

Keywords

None

Examples

```
; Read all the lines from the electrical layer:
oDXF = OBJ_NEW('IDLffDXF')
IF (oDXF->Read('myDXF.dxf')) THEN BEGIN
    contents = oDXF->GetContents(4,COUNT=numLines, $
        LAYER='Electrical')
    IF (numLines ne 0) THEN BEGIN
        lines = oDXF->GetEntity(4,LAYER='Electrical')
    ENDIF
ENDIF
ENDIF
```

Version History

5.2	Introduced
-----	------------

IDLffDXF::RemoveEntity

The IDLffDXF::RemoveEntity procedure method removes the specified entity or entities from the DXF object.

Syntax

Obj->[IDLffDXF::]RemoveEntity[, *Type*] [, INDEX=*value*]

Arguments

Type

An optional scalar string containing the DXF type to be removed from the DXF object.

Note

Specifying a block or layer entity will cause all the entities in that layer or block to be removed.

Keywords

INDEX

Set this keyword to a scalar long or a long array of indices to remove from the DXF object. If not set, or set negative, all entities of the given type are removed.

Version History

5.2	Introduced
-----	------------

IDLffDXF::Reset

The IDLffDXF::Reset procedure method removes all the entities from the DXF object.

Syntax

Obj->[IDLffDXF::]Reset

Arguments

None

Keywords

None

Version History

5.2	Introduced
-----	------------

IDLffDXF::SetPalette

The IDLffDXF::SetPalette procedure method sets the current color table in the object.

Syntax

Obj->[IDLffDXF::]SetPalette, *Red*, *Green*, *Blue*

Arguments

Red

Sets the red components of the current color table to this array.

Green

Sets the green components of the current color table to this array.

Blue

Sets the blue components of the current color table to this array.

Keywords

None

Version History

5.2	Introduced
-----	------------

IDLffDXF::Write

The IDLffDXF::Write function method writes a file for the DXF entity information this object contains.

Syntax

Result = *Obj*->[IDLffDXF::]Write(*Filename*)

Return Value

Returns a 1 if successful in writing the file, 0 otherwise.

Arguments

Filename

A scalar string containing the full path and filename of the DXF file to be written.

Keywords

None

Examples

```

; Write a square to a new DXF file using lines:
oDXF = OBJ_NEW('IDLffDXF')
lines = {IDL_DXF_POLYLINE}
lines.dxf_type = 4
lines.layer='myLayer'
lines.thickness = 1.0

; Create clockwise square:
lines = REPLICATE(lines, 4)
lines[0].vertices = PTR_NEW([[0.0,0.0,0.0], $
    [0.0,1.0,0.0]])
lines[0].connectivity = PTR_NEW([0,1])
lines[1].vertices = PTR_NEW([[0.0,1.0,0.0], $
    [1.0,1.0,0.0]])
lines[1].connectivity = PTR_NEW([0,1])
lines[2].vertices = PTR_NEW([[1.0,1.0,0.0], $
    [1.0,0.0,0.0]])
lines[2].connectivity = PTR_NEW([0,1])
lines[3].vertices = PTR_NEW([[1.0,0.0,0.0], $

```

```
[0.0,0.0,0.0]])
lines[3].connectivity = PTR_NEW([0,1])
oDXF->PutEntity, lines
IF (not oDXF->Write('mySquare.dxf')) THEN $
  PRINT, 'Write Failed.'
  ; Clean up the memory in the structs:
  OBJ_DESTROY, oDXF
  FOR i=0,3 DO BEGIN
    PTR_FREE, lines[i].vertices, lines[i].connectivity
  ENDFOR
```

IDLffJPEG2000

An IDLffJPEG2000 object contains the data for one or more images embedded in a JPEG2000 file as well as functionality for reading and writing JPEG2000 files. For additional information on the JPEG 2000 file format, see “[Overview of IDL and JPEG2000](#)” on page 3380.

Superclasses

None

Creation

See “[IDLffJPEG2000::Init](#)” on page 3409.

Properties

Objects of this class have the following properties. See “[IDLffJPEG2000 Properties](#)” on page 3385 for details on individual properties.

- [BIT_DEPTH](#)
- [BIT_RATE](#)
- [COLOR_SPACE](#)
- [COMMENT](#)
- [DIMENSIONS](#)
- [DISPLAY_RESOLUTION](#)
- [FILENAME](#)
- [JP2](#)
- [N_LAYERS](#)
- [N_LEVELS](#)
- [N_COMPONENTS](#)
- [N_TILES](#)
- [OFFSET](#)
- [PALETTE](#)
- [PROGRESSION](#)
- [QUIET](#)
- [READ](#)
- [REVERSIBLE](#)
- [SIGNED](#)
- [SUBSAMPLING](#)
- [TILE_DIMENSIONS](#)
- [TILE_OFFSET](#)
- [TILE_RANGE](#)
- [UIDS](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

Methods

This class has the following methods:

- [IDLffJPEG2000::Cleanup](#)

- [IDLffJPEG2000::GetData](#)
- [IDLffJPEG2000::GetProperty](#)
- [IDLffJPEG2000::GetTileProperty](#)
- [IDLffJPEG2000::GetUUID](#)
- [IDLffJPEG2000::Init](#)
- [IDLffJPEG2000::SetData](#)
- [IDLffJPEG2000::SetProperty](#)
- [IDLffJPEG2000::SetUUID](#)

Version History

6.1	Introduced
6.2	Added BIT_RATE and UUIDS properties. Added GetUUID and SETUUID methods.

Overview of IDL and JPEG2000

JPEG2000 is an open, international standard for image compression based on wavelet technology. It offers multiple advantages over other image file standards and compression methods. Among these advantages are:

- Low-bit rate compression performance equal to and often above that of other standards.
- Progressive transmission by quality, resolution, component, or region.
- Both lossless *and* lossy compression. (Lossless decompression is achieved naturally via progressions of increasing resolutions and/or quality.)
- Decompression of images which have user-selectable regions, resolutions, and quality.
- Random spatial access to the encoded stream of bits (code stream).
- Support for metadata, in the form of XML boxes.

A JPEG2000 encoded image and its most basic metadata comprise a code stream. This raw code stream may be placed in a file, usually given an extension of .j2k.

The JPEG2000 standard also allows for additional application-specific metadata to be added to a JPEG2000 file. A file that encapsulates the raw code stream and contains this additional metadata is referred to as a JP2 format file. IDL's support of the JP2 standard provides access to the following additional metadata types: color system specifications, palettes, XML containers, and display resolution information. These metadata are exposed through the [COLOR_SPACE](#), [PALETTE](#), [XML](#), and [DISPLAY_RESOLUTION](#) object properties. (See “[Properties](#)” on page 3378).

Note

JP2 format files must always have the file-type extension of .j2k or .jpx (which are case insensitive).

The IDLffJPEG2000 object class in IDL provides access to the features of JPEG2000 and the JP2 file format for both input and output. This object class is detailed in the following section.

Note

Portions of IDL's JPEG2000 functionality were developed using Unisearch's Kakadu software. Kakadu Software. Copyright © 2001. The University of New South Wales, UNSW, Sydney NSW 2052, Australia, and Unisearch Ltd, Australia.

Examples

The following examples showcase various functionality when working with the IDLffJPEG2000 object.

Example One

This example shows how to both use the bit rate keyword to create an image with four layers and how to get and display a specific layer:

```
PRO JP2_BIT_RATE_EXAMPLE

; create a new JPEG2000 file
; the file will have four layers with the given bits rates
oJP2 = OBJ_NEW('IDLffJPEG2000', 'jp2_bit_rate_example.jp2', $
    /WRITE, BIT_RATE=[.02, .022, .032, .1])

; set the image data [256x256]
oJP2->SetData, DIST(256)

; this will release the object
OBJ_DESTROY, oJP2

; open the file we just created
oJP2=OBJ_NEW('IDLffJPEG2000', 'jp2_bit_rate_example.jp2')

; create a window to display the four layers
WINDOW, xsize=512, ysize=512

; get and display each layer
TV, oJP2->GetData(MAX_LAYERS=1), 0
TV, oJP2->GetData(MAX_LAYERS=2), 1
TV, oJP2->GetData(MAX_LAYERS=3), 2
TV, oJP2->GetData(MAX_LAYERS=4), 3

; this will close the file
OBJ_DESTROY, oJP2

END
```

Example Two

This example shows how to add a UUID box to a new JPEG2000 file and how to read a UUID box from an existing JPEG2000 file:

```
PRO JP2_UUID_EXAMPLE

; create a new jp2 file that we can write to
oJP2 = OBJ_NEW('idLFFJPEG2000', 'jp2_uuid_example.jp2', /WRITE)
```

```

; create a bogus id for the uuid box
id = BINDGEN(16)
id[*] = id[*] + 1

; create some data for the uuid box
data = BINDGEN(37)
data[*] = data[*] + 100

; add a new uuid box to the new jp2 file
oJP2->SetUUid, id, data

; set some image data
oJP2->Setdata, BYTARR(10,10, /NOZERO)

; close the file
OBJ_DESTROY, oJP2

; open the file we just created in read only mode
oJP2 = OBJ_NEW('idLffJPEG2000', 'jp2_uuid_example.jp2')

; ask the jp2 object for a list of uuids in the file
; this will return an array of 16 uuids eg..[1,16], [2,16]....
oJP2->GetProperty, UUIDS=uuid_list
HELP, uuid_list

; we get the data for the first uuid found in the file
data1 = oJP2->GetUUid(uuid_list[0,*], LEN=len)
PRINT, 'data len = ', STRTRIM(len,2), ' data = ', data1

; this will cause the object to go away
OBJ_DESTROY, oJP2

END

```

The JPEG2000 Canvas Coordinate System

JPEG2000 uses the concept of the canvas to align multiple image components and tiles in a single coordinate system. This section explains the layout of image components and tiles within the canvas coordinate system.

Image Offsets and Image Subsampling

By default, images are placed on the canvas so that the image and canvas origins align. If an image offset is specified, the origin of all image components will be located at the specified *X* and *Y* offsets from the canvas origin.

Each image component can also be subsampled. The subsampling factors for a component indicate the scaling factor between the component dimensions and the

image dimensions. If an image has dimensions X_I by Y_I , and a component has subsampling factors X_S by Y_S , the dimensions of the component will be the ceiling of X_I/X_S by the ceiling of Y_I/Y_S . For example, suppose an image has an overall size of 512 by 384 samples. An image component that has subsampling factors of 2 by 2 will have dimensions 256 by 192 samples. Calling the `GetData` method to retrieve just this component will return a 256 by 192 array.

In the canvas coordinate system, the subsampling factors have been applied to each component so that the dimensions of all components are always equal.

Note

When reading a region within the image with the `GetData` method, the values passed to the `REGION` keyword (`[StartX, StartY, Width, Height]`) are measured in the canvas coordinate system. The `StartX` and `StartY` values are measured from the canvas origin, and the `Width` and `Height` values are measured after any subsampling has been applied to the image components. This allows a single set of `Width` and `Height` values to be used for every component.

Note

If all components in an image have subsampling factors of 1 by 1, the dimensions of each component will be equal to the value contained in the `DIMENSIONS` property. To calculate the dimensions of individual components when some components have subsamplings other than 1 by 1, the following code can be used:

```
object->GetProperty, DIMENSIONS = dimensions, $
    SUBSAMPLING = subsampling, N_COMPONENTS = n_components
comp_sizes = ULONARR(2, n_components)
FOR i = 0, n_components - 1 do $
    comp_sizes[* , i] = CEIL(FLOAT(dimensions) /
    subsampling[* , i])
```

Tile Dimensions and Tile Offsets

By default, images will have one tile that has the same dimensions and offset on the canvas as the image. If the tile dimensions are smaller than the image dimensions and the tile offsets are different than the images offsets, some tiles may extend beyond the borders of the image.

The values returned via the `TILE_DIMENSIONS` and `TILE_OFFSET` keywords in the `GetTileProperty` method are the dimensions and location of the tile on the image itself, and not necessarily the dimensions and location on the canvas. To determine

the overall dimensions of a tile, whether or not it falls outside the boundaries of the image, check the `TILE_DIMENSIONS` property with the `GetProperty` method.

Figure 30-1: Image Tile Dimensions and Offsets

Saving and Restoring IDLffJPEG2000 Objects

IDL does not save IDLffJPEG2000 objects in a SAVE file. If you restore a SAVE file that contains object references to IDLffJPEG2000 objects, the object references are restored, but are set to null object references. The IDLffJPEG2000 objects are not saved because they contain state information for the external JPEG2000 library. This state information is not available to IDL and cannot be restored.

It is recommended that applications complete any JPEG2000 operations before saving their data in a SAVE file.

IDLffJPEG2000 Properties

IDLffJPEG2000 objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffJPEG2000::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffJPEG2000::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffJPEG2000::SetProperty](#).

Note

For more information about the “Property Type”, “Name String”, and “Registered” columns, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [BIT_DEPTH](#)
- [BIT_RATE](#)
- [COLOR_SPACE](#)
- [COMMENT](#)
- [DIMENSIONS](#)
- [DISPLAY_RESOLUTION](#)
- [FILENAME](#)
- [JP2](#)
- [N_LAYERS](#)
- [N_LEVELS](#)
- [N_COMPONENTS](#)
- [N_TILES](#)
- [OFFSET](#)
- [PALETTE](#)
- [PROGRESSION](#)
- [QUIET](#)
- [READ](#)
- [REVERSIBLE](#)
- [SIGNED](#)
- [SUBSAMPLING](#)
- [TILE_DIMENSIONS](#)
- [TILE_OFFSET](#)
- [TILE_RANGE](#)
- [UUIDS](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

BIT_DEPTH

An integer vector containing the bit depth for each image component. Values must be in the range 1 ... 24.

Note

When writing out JPEG2000 files, the default BIT_DEPTH is 8 for all components, regardless of the data type supplied to SetData. If you are writing out short or long integer data, you may wish to set BIT_DEPTH to a larger value for those components.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

BIT_RATE

A floating-point vector containing the bit rate for each layer, measured in bits per pixel per component (or band). The number of elements in BIT_RATE must be equal to the number of quality layers or, alternatively, may be two.

When writing files, the values in BIT_RATE may be given in any order, and will be automatically sorted into ascending order. A value of -1 anywhere within the BIT_RATE vector indicates that the highest quality layer should include all compressed bits. BIT_RATE may also be set to a two-element vector, in which case the rates will be approximately logarithmically spaced between the two values.

When the /REVERSIBLE switch is set the last rate will be automatically set to -1 to ensure that the last layer contains the bits needed to recreate the original image data.

When the number of rates being set exceeds the number of layers being set an error is thrown. The value in the N_LAYERS property must always be equal to or greater than the number of bit rates in the BIT_RATE property (unless the number of bit rates is two).

Property Type	Float Vector		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

COLOR_SPACE

A string containing one of the following values:

- sLUM - a luminance (monochrome) space.
- sRGB - the sRGB space is a reasonably good model for color imagery which has been corrected to look good on a monitor.
- sYCC - a three-component color space derived by applying the standard YCbCr color transform to sRGB data; the YCbCr transform is identical to

the irreversible color transform defined by JPEG2000 at the code stream level.

- iccLUM - a monochrome color space defined by an embedded ICC profile.
- iccRGB - an RGB color space defined by an embedded ICC profile.
- <Null string> - none of the above. A null string will result if the source is not a JP2 source.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COMMENT

A string vector containing an element for each comment associated with the object. If the object has no associated comments, the result will be a scalar null string.

Property Type	String Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

A two-element 64-bit integer array giving the width and height of the image. Values for DIMENSIONS should be in the range $1 \dots 2^{32}-1$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DISPLAY_RESOLUTION

A two-element floating-point vector giving the default horizontal and vertical display resolution (in samples per meter). This property will return a value of [0.0, 0.0] if the file has no display resolution specified. This keyword is only valid for JP2 files.

Note

The JPEG2000 code stream stores the display resolution values using only 24 bits of precision. When writing files, you may notice slight differences between your input values and the values returned when reading the file.

Property Type	Float Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILENAME

A string containing the name of the file associated with the object

Note

This property can only be set via the *Filename* argument to the [IDLffJPEG2000::Init](#) method.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

JP2

A boolean value indicating whether the JPEG2000 file consists of only a codestream (usually referred to as a `.j2c` file) or of a codestream and metadata information (usually referred to as a `.jp2` or `.jpx` file).

Note

This property can only be set when the IDLffJPEG2000 object is created.

When writing a JPEG2000 file (that is, when the WRITE property is set to 1):

- If the JP2 property is set to 1, the file created will contain a codestream and metadata (`.jp2` file type), regardless of the file extension specified.
- If the JP2 property is set to 0, the file created will contain only a codestream (`.j2c` file type), regardless of the file extension specified.

- If the JP2 property is *not set* when the IDLffJPEG2000 object is created:
 - If the file extension specified is either `.jp2` or `.jpx`, the file created will contain both codestream and metadata (`.jp2` file type).
 - If the file extension is anything other than `.jp2` or `.jpx`, the file created will contain only the codestream (`.j2c` file type).

When reading a JPEG2000 file:

- The JP2 property will be set to 1 if the file contains both codestream and metadata.
- The JP2 property will be set to 0 if the file contains only the codestream.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

N_COMPONENTS

An integer containing the number of image components (or channels) in the entire file or code stream. If `N_COMPONENTS` is not supplied in the first call to `Init` or `SetProperty`, it will be the same as the number of components contained in the image parameters in the first call to `SetData`.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_LAYERS

A positive integer specifying the number of quality layers. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers, each containing a further quality refinement.

When writing, the default is one. If `N_LAYERS` is greater than one, the layers will be assigned roughly logarithmically-spaced bit rates, with the last layer containing all of

the compressed bits. A larger number of layers takes longer to encode and produces a larger file, but provides more flexibility when decoding.

When setting `N_LAYERS`, the value is limited to 244

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_LEVELS

An integer specifying the number of wavelet decomposition levels, or stages, in the range of 0...15. Higher values will typically give better compression.

When writing files, a value of zero indicates that no wavelet transform will be used. If this keyword is omitted, then the default value of 5 is used. When writing JP2 files, if the `PALETTE` property is set then the default is `N_LEVELS=0`.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_TILES

An integer specifying the number of tiles within the file.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

OFFSET

A two-element integer array giving the X and Y offsets of all image components. Values for `OFFSET` should be positive, in the range of a 32-bit integer 0 ... $2^{31}-2$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

JP2 files may contain a “palette”, or color table, which efficiently stores images with only a few distinct colors. The palette associates a color index with each distinct color present in the image. Images stored in JP2 files with a palette consist of only one component which contains the color indices.

When writing a JP2 file, set this property to a 3-by- n or an n -by-3 array of byte or integer values, where n is the number of intensity values, for the three color channels of red, green, and blue. In this case n must be a power of 2 and ≤ 256 .

When reading JP2 files, this property will return an n -by- m array of byte or integer values, where n is the number of intensity values, and m is the number of lookup tables (m is usually 3, indicating red, green, and blue). If the associated object has no palette, this property will return a scalar zero.

Note

When writing JP2 files, if PALETTE is present, then the default values for other properties are N_LEVELS=0, REVERSIBLE=1, and YCC=0.

Property Type	Byte or Integer Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROGRESSION

A string defining the progression order of the output. Progression order may be one of the following: LRCP, RLCP, RPCL, PCRL, CPRL. The four character identifiers have the following interpretation: L = layer; R = resolution; C = component; P = position. Data is written to the output file iteratively over the four progression identifiers in this string, that is, the output is written in four nested iteration levels. The first character in the identifier refers to the outermost level of the iteration, while the last refers to the innermost level. The default is LRCP. This property is ignored when used with files opened for reading.

For example, “LRCP” means that an image is encoded in the following order, with quality being the outermost loop:

- L - a series of one or more quality layers, each contributing a quality increment for the entire image at full resolution. The quality layers may be interpreted as

sub-bitplanes containing the image data at a specified, possibly fractional, bit-rate.

- **R** - each resolution level of the image, which corresponds to the `N_LEVELS` keyword used in encoding, and can be considered to contain the image data at a given size or resolution. Each level adds another level of detail to the previous levels.
- **C** - each image component of the above.
- **P** - each position (tile) within the image component.

In this example, if an image consists of 2 quality layers, 5 resolution levels, 3 components, and 16 positions or tiles, the image would be encoded in a series of packets as follows:

```

POC0R0L0, P1C0R0L0, P2C0R0L0, ..., P15C0R0L0
POC1R0L0, P1C1R0L0, P2C1R0L0, ..., P15C1R0L0
POC2R0L0, P1C2R0L0, P2C2R0L0, ..., P15C2R0L0
POC0R1L0, P1C0R1L0, P2C0R1L0, ..., P15C0R1L0
POC1R1L0, P1C1R1L0, P2C1R1L0, ..., P15C1R1L0
POC2R1L0, P1C2R1L0, P2C2R1L0, ..., P15C2R1L0
... ..
... ..
... ..
POC2R4L0, P1C2R4L0, P2C2R4L0, ..., P15C2R4L0

POC0R0L1, P1C0R0L1, P2C0R0L1, ..., P15C0R0L1
POC1R0L1, P1C1R0L1, P2C1R0L1, ..., P15C1R0L1
POC2R0L1, P1C2R0L1, P2C2R0L1, ..., P15C2R0L1

```

This encodes all components over the entire image at a given quality level, before sending the next quality refinement.

When encoding a large image with a large number of components, memory requirements will be minimized by sending each component by means of a separate call to `SetData`, and by specifying a progression order of “CPRL”.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

QUIET

A boolean that when set to a non-zero value suppresses the printing of warnings for this object. The default is not to suppress warnings.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

READ

A boolean set to 1 if the file is to be accessed for reading. The default is to open the file for reading.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

REVERSIBLE

A boolean that specifies the type of compression that should be used. A non-zero value indicates that reversible (lossless) compression should be used. The default is to use irreversible compression. When writing JP2 files, if the PALETTE property is set then the default is REVERSIBLE=1.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SIGNED

An n -element boolean vector where n is the number of components. A value of one indicates pixels in that component are interpreted as signed numbers, otherwise the pixels are interpreted as unsigned numbers. The default is to interpret the numbers as unsigned.

Note

When writing out JPEG2000 files, the default is SIGNED=0 for all components, regardless of the data type supplied to SetData. If you are writing out signed integer data, you should set SIGNED to 1 for those components.

Property Type	Boolean Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBSAMPLING

A 2 by N_COMPONENTS integer array containing the subsampling factors in the horizontal and vertical dimensions for each image component. The dimensions of each component will be the ceiling of the image dimensions divided by the respective subsampling factor.

Property Type	Integer Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

TILE_DIMENSIONS

A 2-element integer vector defining the width and height of each tile. When writing files, the default is to write one tile with the same dimensions as the image parameter. Values for TILE_DIMENSIONS should be in the range 1 ... $2^{32}-1$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_OFFSET

A 2-element integer vector containing the X and Y offset of the first tile on the canvas.

When reading, the TILE_OFFSET will return the X and Y offset of the first tile. The GetTileProperty method may be used to retrieve the TILE_OFFSET for other tiles.

When writing, the default is `TILE_OFFSET=[0,0]`. The values of `TILE_OFFSET` must be less than or equal to the corresponding values of the `OFFSET` property. Values for `TILE_OFFSET` should be positive, in the range 0 to $(2^{31})-2$.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_RANGE

A two-element integer vector giving the number of tiles in the X and Y directions.

Property Type	Integer Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UUIDS

This property provides a mechanism to retrieve the Universally Unique Identifiers (UUIDs) for the UUID boxes in the JPEG2000 file.

A JPEG2000 file can contain 0-*n* number of UUID boxes. A UUID is a 16 byte value. Each UUID box is made up of a UUID field and a user data field. A UUID box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

The property returns one of the following:

- a scalar value of 0 when the file does not contain any UUID boxes
- a 16 x *n* byte array, where *n* is the number of UUIDs included. UUID boxes that exist in the file but do not contain any data are not included in the returned array.

For example, if the file contains 10 UUID boxes then this property returns a 16x10 byte array.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

WRITE

A boolean that is 1 if the object is open for writing, 0 if not.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

XML

A string vector, with each element containing the XML string of a corresponding JP2 XML box. When creating a JP2 file, call this property with a string value to add the corresponding XML to the JP2 file. This property can be set multiple times. Each time it is set, the corresponding string will be added to a separate XML box.

When reading a JP2 file, if the file does not contain any XML boxes, the property returns a null string. If the file contains a single XML box, the property will return a single string containing the entire contents of the XML box. If the file contains multiple XML boxes, the property will return an array of strings, each containing the contents of an entire XML box.

This keyword is only valid for JP2 files.

Here are a few tips for working with XML in JP2 files and IDLffJPEG2000 objects:

- An XML box can hold plain text as well as XML text.
- There can be multiple XML boxes in JP2 files.
- To parse the JP2 file XML tag with the IDL SAX parser, read the XML tag and store the XML string in a variable. You can then parse the variable directly with the IDLffXMLSAX::ParseFile method.
- To parse the JP2 file XML tag with the IDL DOM parser, read the XML tag and save the XML string in a temporary file. You can then pass the file to IDLffXMLDOMDocument.
- You cannot pass a J2K file directly to an IDL parser.

Property Type	String Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCC

When reading files, this property indicates whether the data was originally converted from the RGB color space to the YCC color space. If YCC is true, then when calling `GetData`, you may wish to return all three image components so that the YCC data can be correctly transformed back to RGB.

When writing files, set this property to a boolean which specifies whether RGB data should be converted to YCrCb before being written. If the image being written has three components, the default is to assume the image contains RGB components, which are automatically converted to YCrCb, and then written. The default action to convert RGB to YCC may be overridden by explicitly setting the YCC keyword to zero. When writing JP2 files, if the PALETTE property is set then the default is YCC=0. If the image being written does not have three components, this property is ignored.

Transforming the color coordinates from RGB to YCC decorrelates the three color components and improves compression performance for RGB images. JPEG2000 readers will then convert back to RGB.

Note

For the RGB-to-YCC conversion to occur, all three components must be provided at the same time (either the entire image or as separate tiles). If the components are provided in separate calls to `SetData`, the YCC conversion is not performed.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffJPEG2000::Cleanup

The IDLffJPEG2000::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Note

Calling OBJ_DESTROY will also close any files that have been opened for reading or writing.

Syntax

OBJ_DESTROY, *Obj*

or

Obj -> [IDLffJPEG2000::]Cleanup (*In a lifecycle method only.*)

Arguments

None

Keywords

None

IDLffJPEG2000::GetData

The IDLffJPEG2000::GetData function method returns image data from the IDLffJPEG2000 object.

Syntax

```
Result = Obj->[IDLffJPEG2000::]GetData( [, COMPONENT=value]
    [, DISCARD_LEVELS=value] [, MAX_LAYERS=value]
    [, N_COMPONENTS=value] [, ORDER=value] [, REGION=value] [, /RGB]
    [, TILE_INDEX=value])
```

Return Value

An array with two or three dimensions containing the image data from the object. Dimensions of the result are: [3, *Width*, *Height*] if the RGB keyword is set; or [*nComponents*, *Width*, *Height*] if the RGB keyword is not set. *nComponents* is the number of components present in the file. Images with only one component (which are read with RGB not set) return a two dimensional array [*Width*, *Height*].

The data type of the result is automatically determined using the bit-depth and signed properties of the returned components. For bit-depths ≤ 8 (or if RGB is set) the result will be of type byte. For bit-depths ≥ 9 and ≤ 16 the result will be of type integer or uint. For bit-depths > 16 the result will be long or ulong. Components with differing bit-depths will be returned using the largest bit-depth. Components which are a mix of signed and unsigned will be returned as signed.

Note

If the PERSISTENT keyword was set to zero when the object was created, the object may not be accessed after GetData is called, with the exception of the GetProperty and Cleanup methods.

Note

If the data in the file was transformed from RGB to YCC before saving, the library will only transform back from YCC to RGB if all three components are read in simultaneously. Reading in each component separately will return the data in the YCC space. The YCC property may be used to determine if the RGB-to-YCC conversion took place. If YCC is true, you may wish to avoid using the COMPONENT or N_COMPONENTS keywords.

Keywords

COMPONENT

Set this keyword to an integer giving the index of the component at which to start reading. The number of components to read may be specified using the `N_COMPONENTS` keyword. The default is `COMPONENT=0`.

DISCARD_LEVELS

Set this keyword to an integer that indicates the number of resolution levels to be discarded, starting with the highest resolution level (the full image).

For example, setting this keyword equal to 2 will discard the two highest resolution levels — that is, the full- and half-resolution images. The returned array will contain the quarter-resolution image.

The resulting image dimensions are given by:

$$\text{CEIL}((\text{Dimensions} + \text{Offset}) / (2^{\text{DL}})) - \text{CEIL}(\text{Offset} / (2^{\text{DL}}))$$

where *Dimensions* and *Offset* are the image dimensions and offset, and *DL* is the value of `DISCARD_LEVELS`.

MAX_LAYERS

Set this keyword to the maximum number of quality layers which will appear to be present. A quality layer is one quality increment for the entire image at full resolution. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. All image data bits may be encoded in one layer, or may be broken up into a larger number of layers each containing a further quality refinement. A value of 0, the default, implies that all layers should be retained. For example, specifying `MAX_LAYERS = 4` processes only the first four quality layers. The number of quality layers in a file may be determined by checking the value of the `N_LAYERS` property.

N_COMPONENTS

Set this keyword to an integer giving the number of components to read, starting at the component index given by the `COMPONENT` keyword. If neither `COMPONENT` nor `N_COMPONENTS` is specified then all components will be read. If `COMPONENT` is specified then the default is `N_COMPONENTS=1`.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `GetData` will automatically flip the result to match IDL's bottom-to-top order. Setting `ORDER` to a nonzero value will return the JPEG2000 image without doing the vertical flip.

Tip

If you are reading a tiled image and displaying the tiles in an `IDLgrImage` object, using IDL's default ordering will result in the individual tiles being correctly oriented, but displayed out of sequence. To ensure that tiles are displayed in the correct sequence, set both the `ORDER` keyword to the `GetData` method and the `ORDER` property of the `IDLgrImage` object to one.

REGION

Set this keyword to a four-element vector containing the rectangular region of the image to read in the canvas coordinate system. The region is specified as [`StartX`, `StartY`, `Width`, `Height`], where `StartX` and `StartY` must be in the range $0 \dots 2^{32}-2$, and `Width` and `Height` must be in the range $1 \dots 2^{32}-1$. The region must contain at least some portion of the image, or an error will occur. If the region is larger than the image, or extends outside of the image, then only that portion that lies within the image will be returned.

Note

The region parameters should be specified in the canvas coordinate system, taking into account the canvas offset and canvas dimensions.

RGB

If this keyword is set, the data stream will be interpreted as RGB imagery and all details concerning color transformations (for example: `sRGB`, `sLUM` and `sYCC`), together with restricted ICC-profiles for specifying more general 3-color "RGB-like" spaces, plus indexed color with palettes, are handled automatically. If this keyword is set, the result of this function will always have three components, red, green, and blue; and the dimensions of the result will be [`3`, `Width`, `Height`].

The JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the `YCC` keyword returned by the `::GetTileProperty` method.

If RGB is set and the file contains more than three components, only the first three components are returned. If RGB is set and the file contains less than three components an error is issued.

If RGB is not set, and three components are transferred, and a color transformation has been applied to the input stream, the three components which are encoded in a form of YCC will automatically be converted to RGB. If it is desired to avoid this conversion, then the user should transfer more or less than three components in the call or calls to GetData.

If RGB is not set and the number of components is not three, then each component in the data stream will be placed in the result without interpretation. Result will have dimensions: [N_COMPONENTS, *Width*, *Height*].

The RGB keyword may not be specified if the COMPONENT or N_COMPONENTS keywords are present.

TILE_INDEX

Set this keyword to an integer giving the tile index to read. If this keyword is specified then the REGION keyword is ignored.

Examples

This example illustrates the use of GetData to read an image a number of different ways:

```
;Create object, open file.
a = OBJ_NEW('IDLffJPEG2000', 'boat2.jp2')

;Read the entire image.
b = a->GetData()

;Read a 512x512 portion of the image, starting
;at column 100, row 200.
b = a->GetData(REGION = [100, 200, 512, 512])

;Read the portion of the above, but sub-sample it down by a
;factor of 2, returning an nComponents x 256 x 256 image.
b = a->GetData(REGION = [100, 200, 512, 512], DISCARD_LEVELS=1)

;Read only the 2nd component.
;The result will have two dimensions.
b = a->GetData(COMPONENT = 1)
```

Version History

6.1	Introduced
-----	------------

IDLffJPEG2000::GetProperty

The IDLffJPEG2000::GetProperty procedure method returns information describing the properties of an IDLffJPEG2000 object in the supplied variable - keyword pairs.

Syntax

Obj->[IDLffJPEG2000::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLffJPEG2000 Properties](#)” on page 3385 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.1	Introduced
-----	------------

IDLffJPEG2000::GetTileProperty

The IDLffJPEG2000::GetTileProperty procedure method returns information describing the properties of a tile in an IDLffJPEG2000 object in the supplied variable-keyword pairs. The object must be open for reading. An error is produced if the object is open for writing.

Syntax

```
Obj->[IDLffJPEG2000::]GetTileProperty [, TileIndex [, TileComponent]],  
    [, N_LAYERS=variable] [, N_LEVELS=variable] [, PROGRESSION=variable]  
    [, REVERSIBLE=variable] [, TILE_DIMENSIONS=variable]  
    [, TILE_OFFSET=variable] [, YCC=variable]
```

Arguments

TileIndex

This argument specifies the index of the tile whose attributes are to be returned. JPEG2000 tiles are numbered in raster scan fashion, starting from 0 and going up to a maximum of 65535. The default value for this argument is 0.

TileComponent

This argument specifies the component index of the tile whose attributes are to be queried. Indices range from 0 to N_COMPONENTS-1. The default value for this argument is 0.

Keywords

N_LAYERS

Set this keyword to a named variable in which to return the number of quality layers available for the tile. If this keyword is set, the TileComponent argument is ignored.

N_LEVELS

Set this keyword to a named variable in which to return the total number of available resolution levels for this tile component.

PROGRESSION

Set this keyword to a named variable in which to return a string containing the progression order for that tile. The returned value will be one of: LRCP, RLCP, RPCL, PCRL, CPRL.

See “[PROGRESSION](#)” on page 3391 under Properties for the definition of these values.

REVERSIBLE

Set this keyword to a named variable in which to return 1 if the tile-component is compressed reversibly, 0 if irreversible.

TILE_DIMENSIONS

Set this keyword to a named variable in which to return a two-element vector containing the width and height of the tile, taking into account any clipping of the tile to the image.

TILE_OFFSET

Set this keyword to a named variable in which to return a two-element vector containing the horizontal and vertical offset of the tile, taking into account any clipping of the tile to the image.

YCC

Set this keyword to a named variable in which to return 1 if a component color transform was used for the first 3 components of the tile specified by the TileIndex argument, 0 otherwise.

Version History

IDLffJPEG2000::GetUUID

The IDLffJPEG2000::GetUUID function method allows you to get the data field from the specified UUID box.

A JPEG2000 file can contain 0-*n* number of UUID boxes. Each UUID box in a JPEG2000 file is made up of a UUID field and a user data field. A UUID box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier.

Syntax

Data = *Obj*->[IDLffJPEG2000::]GetUUID(*UUID* [, **LENGTH**=*length*])

Return Value

Returns one of the following:

- a scalar zero when the passed in UUID is not found in the file
- a byte array containing the data found in the data field of the UUID box.
- a scalar zero when the passed UUID is found in the file but does not contain any data (i.e. the data field is empty).

Arguments

UUID

The UUID argument is required. The UUID argument must be a 16 byte array.

Keywords

LENGTH

Length is an optional keyword. If present, the length variable will be set to the number of bytes in the returned data array. If present and the requested UUID is not found, length will be 0. If present and the requested UUID is found but does not contain any data (i.e. the data field is empty), the length will be -1.

Version History

6.2	Introduced
-----	------------

IDLffJPEG2000::Init

The IDLffJPEG2000::Init() function method initializes an IDLffJPEG2000 object that can be used to read (decode) image data from a JPEG2000 image file, or write (encode) image data to a JPEG2000 image file.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLffJPEG2000' , Filename [, /PERSISTENT]  
          [, PROPERTY = value])
```

or

```
Result = Obj->[IDLffJPEG2000::]Init(Filename [, /PERSISTENT]  
          [, PROPERTY = value]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

Set this argument to a scalar string containing the path and filename of a file containing JPEG 2000 compressed image data to be accessed through this object. If the file type suffix is .jp2 or .jpx, case insensitive, the file is a JP2 file. Otherwise the file contains a raw JPEG2000 code stream.

Note

The value specified by the *Filename* argument is used to initialize the value of the **FILENAME** property of the IDLffJPEG2000 object.

Keywords

In addition to the following keyword, any property listed under “**IDLffJPEG2000 Properties**” on page 3385 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

PERSISTENT

A boolean value that indicates whether the image contained in the object may be accessed more than once. If set to zero, the image contained within the object may not be accessed more than once, and data are discarded whenever possible, minimizing memory usage. The default is PERSISTENT=1, which allows access to the image multiple times. This keyword is ignored if the file is opened for writing

Version History

6.1	Introduced
-----	------------

IDLffJPEG2000::SetData

The IDLffJPEG2000::SetData procedure method writes data to the IDLffJPEG2000 object.

Syntax

```
Obj->[IDLffJPEG2000::]SetData, P1, ..., Pn [, COMPONENT=value] [, /ORDER]
    [, TILE_INDEX=value]
```

Arguments

P₁, ... , P_n

Arguments may be one or more arrays containing the image components or tile components to be written to the JPEG2000 object. The arrays may have either two or three dimensions. Two-dimensional arrays contain one image or tile component with the dimensions of width and height. Three-dimensional arrays are dimensioned [*nComponents*, *width*, *height*]. All parameters must have the same width and height.

The array parameters are converted to byte data type if the bit-depth for the corresponding component is less than or equal to 8; to signed or unsigned integer, depending on the signed setting, for bit-depths from 9 - 16; and to signed or unsigned long integers, depending on the signed setting for bit-depths over 16.

Note

The bit depths used for output are determined from the BIT_DEPTH property, and not from the data type of the input arguments. If you are writing out short or long integer data, you should set the BIT_DEPTH property before calling SetData.

Note

The SIGNED property determines whether the data are written out using signed or unsigned integers, and is not affected by the data type of the input arguments. If you are writing out signed integer data, you may wish to set the SIGNED property before calling SetData.

Image Dimensions, Tile Dimensions, and Component Number

Images may be written using multiple calls to SetData with each call transferring one or more tile components. A tile component contains one image component for a given tile and is the smallest unit of data that can be supplied to SetData. The dimensions of the entire image and tiles, plus the number of components are determined the first

time they are specified to `Init` or `SetProperty`, and may not be changed once established. If the dimensions or number of components are not specified explicitly they are inferred from the image parameters supplied in the first call to `SetData`.

If transferring an image with multiple calls to `SetData`, try to supply the data to `SetData` in a manner consistent with the progression setting of `PROGRESSION` to ensure optimum performance and minimize memory requirements.

Note

If you do not complete writing all of the tiles or components, or your array dimensions are not the same as the overall image dimensions, then the library will be unable to complete the code stream. In this case, reading the data back in may result in unexpected or incorrect values.

Note

If the `YCC` property is set (indicating that you want the library to convert from `RGB` to `YCC` before compressing the data), then you must supply all three image components in the same call to `SetData` (either the entire image or one tile at a time). If the components are provided in separate calls to `SetData`, the `YCC` conversion is not performed.

Keywords

COMPONENT

Set this keyword to be the index of the first component to be written by this call to `SetData`. Default is 0.

ORDER

JPEG2000 images are assumed to be stored in top-to-bottom order, while IDL usually assumes images are in bottom-to-top order. By default (`ORDER = 0`), `SetData` will automatically flip the input arrays to match JPEG2000's top-to-bottom order. Setting `ORDER` to a nonzero value will save the image directly to the JPEG2000 file without doing the vertical flip.

TILE_INDEX

Set this keyword to specify the index of the first tile to be written. JPEG2000 tiles are numbered in raster scan fashion, starting from 0. The default value for this keyword is 0. The tile indices must range from 0 to one less than the number of tiles in the image file, which is determined by the tile dimensions and image dimensions.

Examples

Write a one-component image:

```
;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE)

;Write the image
jp2->SetData, BYTSCL(DIST(400,300))

OBJ_DESTROY, jp2
```

Read a one-component image:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

img = jp2_in->GetData() ; Read the file.

OBJ_DESTROY, jp2_in
```

Write an indexed-color image with a palette:

```
;Load IDL color table #5, this example assumes we have 256 colors.
LOADCT, 5

;Read color tables
TVLCT, /GET, Red, Green, Blue

;Open file to write
jp2 = OBJ_NEW('IDLffJPEG2000', 'test.jp2', /WRITE, /JP2, $
  PALETTE=[Red], [Green], [Blue])

;Write the image with the palette
jp2->SetData, BYTSCL(DIST(400,300))
OBJ_DESTROY, jp2
```

Read the above image and palette:

```
;Open file to read
jp2_in = OBJ_NEW('IDLffJPEG2000', 'test.jp2')

jp2_in->GetProperty, PALETTE=palette

;Read without RGB keyword. img is a 400 by 300 byte image.
img = jp2_in->GetData()

;With the RGB keyword, the image is now [3, 400, 300]
img3d = jp2_in->GetData(/RGB)

OBJ_DESTROY, jp2_in
```

Show the images:

```
TVLCT, palette[* , 0], palette [* , 1], palette[* , 2]
DEVICE, DECOMPOSED = 0
TV, img
DEVICE, DECOMPOSED = 1
TV, img3d, TRUE=1
```

Write a 100 component file, one component at a time:

```
j2k = OBJ_NEW('IDLffJPEG2000', 'test.j2k', /WRITE,
             N_COMPONENTS=100)
FOR i = 0, 99 DO j2k_in->SetData, $
    replicate(byte(i), 200, 300), COMPONENT = i
OBJ_DESTROY, j2k_in
```

Read the above file:

```
j2k_in = obj_new('IDLffJPEG2000', 'test.j2k')

;b is a [200, 300] array
b = j2k_in->GetData(COMPONENT=30)

;b is a [5, 200, 300] array
b = j2k_in->GetData(COMPONENT=50, N_COMPONENT = 5)

OBJ_DESTROY, j2k_in
```

Version History

-----	------------

IDLffJPEG2000:: SetProperty

This procedure sets the properties of an object that is open for writing. This method may not be called on files opened for reading.

Syntax

Obj->[IDLffJPEG2000::]SetProperty [, *PROPERTY=value*]

Arguments

None.

Keywords

Any property listed under “[IDLffJPEG2000 Properties](#)” on page 3385 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.1	Introduced
-----	------------

IDLffJPEG2000::SetUUID

The IDLffJPEG2000::SetUUID procedure method allows you to add UUID boxes when creating a new JPEG2000 file. This method can only be called when the JPEG2000 object was created with the WRITE property set. Each call to SetUUID will add a new *uuid box* to the JPEG2000 file.

A JPEG2000 file can contain zero or more uuid boxes. Each uuid box is made up of a uuid field and a user data field. A uuid box allows the user to store application specific data inside a JPEG2000 file using a universally unique identifier. User data is not compressed when the file is written.

Syntax

Obj->[IDLffJPEG2000::] SetUUID, *uuid*, *Data*

Arguments

uuid

The *uuid* argument must be a 16 byte array. If *uuid* passed in already has been used in a previous SetUUID call, an error is issued. The *uuid* is written into the uuid field of the new uuid box.

Data

The *Data* argument must be an array. The array can be of any type and any length. SetUUID treats the array as a stream of bytes. The stream of bytes are written into the data field of the new uuid box.

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffLangCat

The IDLffLangCat class is used to find and load an XML language catalog. A language catalog is composed of key names and key values. The key value of the specified key name can be retrieved to support internationalization. For example:

```
<KEY NAME='Menu:File:Open'>Open...</KEY>
```

in an English language catalog would appear as the following in a French language catalog:

```
<KEY NAME='Menu:File:Open'>Ouvrir...</KEY>
```

By handling files that contain keys and values like these, the IDLffLangCat class supports internationalization of user interfaces and other applications that need to display the same strings in more than one language.

The language catalogs included with IDL are in the `<IDL_DIR>/resource/langcat` directory and end in a `.cat` extension. You can use other catalogs, but all catalogs must end with the `.cat` extension.

Note

The IDLffLangCat class supports catalog files written in 8-bit strings (which can be encoded for languages using special marks; see below). Also, you must have the corresponding fonts installed on your machine before you can use a particular language.

A language-catalog file can support accent marks such as those in French (which stray from the first 128 character codes defined by ASCII into the ISO-8859 encodings) if you do one of the following actions:

- Add `encoding='ISO8859-1'` to the XML tag element at the beginning of the file (e.g., `<xml version='1.0' encoding='ISO8859-1'?>`)
- Save the XML file as Unicode

In general, you should use the encoding appropriate for your catalog's language. For the list of supported encodings and for more general information about XML, see [“About XML”](#) (Chapter 20, *Application Programming*).

Note

For more information on this class, including examples of how to use it, see [“Using Language Catalogs”](#) in the *Building IDL Applications* manual.

Superclasses

None

Creation

See `IDLffLangCat::Init`.

Properties

Objects of this class have the following properties. See “[IDLffLangCat Properties](#)” on page 3420 for individual properties.

- `APP_NAME`
- `APP_PATH`
- `AVAILABLE_LANGUAGES`
- `DEFAULT_KEYS`
- `DEFAULT_LANGUAGE`
- `DEFAULT_N_KEYS`
- `FILENAME`
- `KEYS`
- `LANGUAGE`
- `N_KEYS`
- `VERBOSE`

Methods

This class has the following methods:

- `IDLffLangCat::AppendCatalog`
- `IDLffLangCat::Cleanup`
- `IDLffLangCat::GetProperty`
- `IDLffLangCat::Init`
- `IDLffLangCat::Query`
- `IDLffLangCat::SetProperty`

Version History

6.1	Introduced
-----	------------

IDLffLangCat Properties

IDLffLangCat objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffLangCat::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffLangCat::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffLangCat::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [APP_NAME](#)
- [APP_PATH](#)
- [AVAILABLE_LANGUAGES](#)
- [DEFAULT_KEYS](#)
- [DEFAULT_LANGUAGE](#)
- [DEFAULT_N_KEYS](#)
- [FILENAME](#)
- [KEYS](#)
- [LANGUAGE](#)
- [N_KEYS](#)
- [VERBOSE](#)

APP_NAME

The name of one or more current applications, returned in alphabetical order.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

APP_PATH

The directory or directories searched for each given application. Each directory path must be fully qualified and unambiguous (e.g., C:\ITT\IDLxx\lib\itools).

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

AVAILABLE_LANGUAGES

A list of all languages that exist in the input file or files. When APP_NAME is specified, this property returns all languages where the language-catalog files have the same internal application name. The languages return in alphabetical order.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DEFAULT_KEYS

A list of all the currently loaded keys in the default language.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DEFAULT_LANGUAGE

The current default language.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

DEFAULT_N_KEYS

The number of currently loaded keys in the default language.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

FILENAME

The name of each currently loaded language catalog (.cat) file. In setting this property, each name is either a fully qualified path (e.g., C:\ITT\IDLxx\resource\langcat) to a location containing a file, or the name of a file in the current directory. In getting this property, it always returns the full path.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

KEYS

A list of all the currently loaded keys, returned in upper-case.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

LANGUAGE

The current language.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_KEYS

The number of currently loaded keys.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

VERBOSE

The current setting of the verbose flag. If set, all catalog-loading messages will be sent to the output window. This list contains details resulting from an IDLffLangCat object initialization or modification, including the names and numbers of keys loaded, keys overwritten, and so on.

Property Type	Byte		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffLangCat::AppendCatalog

The IDLffLangCat::AppendCatalog function method adds keys from a file or files to those used to build the language catalog. All valid keys present in the current language will be inserted into the current key/value list. If any new languages are present in the new files, they will be added to the AVAILABLE_LANGUAGES property. If a duplicate key name is found, its value will replace the existing key name's value.

Note

Whenever the object encounters a key (or language) that already exists, the key (or language) is overwritten with the new value.

Syntax

```
Result = Obj->[IDLffLangCat::]AppendCatalog( [, APP_NAME=applicationName]  
[, FILENAME=filename] [, APP_PATH=applicationPath] )
```

Return Value

Returns 1 if valid keys were found and loaded, or 0 otherwise.

Arguments

None

Keywords

APP_NAME

Set this keyword to a string or string array containing the name of each desired application for which to add keys. If APP_NAME is specified, it overrides any input to FILENAME. You can use the '*' wild card (e.g., 'MyApp*' instead of ['MyAppMenu', 'MyAppErrors', ...]). You must provide either APP_NAME or FILENAME.

APP_PATH

Set this keyword to a string or string array containing the name of each directory in which to search for the given application's keys. Each path must be fully qualified

(e.g., `C:\ITT\IDLxx\lib\itools`). This keyword is ignored if `APP_NAME` is not specified.

FILENAME

Set this keyword to a string or string array containing the name of each language-catalog file to load. If `APP_NAME` is specified, it overrides any input to `FILENAME`. Each string is either a fully qualified path (e.g., `C:\ITT\IDLxx\resource\langcat`) to a location containing a file, or the name of a file in the current directory. You must provide either `APP_NAME` or `FILENAME`.

Version History

6.1	Introduced
-----	------------

IDLffLangCat::Cleanup

The IDLffLangCat::Cleanup procedure method performs all cleanup operations on the language catalog object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffLangCat:]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffLangCat::GetProperty

The IDLffLangCat::GetProperty procedure method retrieves a property or group of properties for an IDLffLangCat object.

Comparisons such as those done with [IDLffLangCat::Query](#) are case insensitive, but the values returned by GetProperty are exactly as the last encountered value. For example, if File 1 has LANGUAGE= 'English' and File 2 has LANGUAGE= 'engLIsh', then 'engLIsh' will be returned, although only one ENGLISH language exists in the current catalog.

Syntax

Obj->[IDLffLangCat::](#)GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under [“IDLffLangCat Properties”](#) on page 3420 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.1	Introduced
-----	------------

IDLffLangCat::Init

The IDLffLangCat::Init function method initializes an IDLffLangCat object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Any invalid input will result in a failure to create a valid object. Invalid input includes the following cases:

- The requested language is not found in any of the input files
- Any application in APP_NAME is not found
- Any file in FILENAME is not found
- Any directory in APP_PATH does not exist
- The requested default language is not found

You can set the VERBOSE keyword to view the output log for a detailed description of the creation (or failure) of the object. You can also set [CONTINUE_ON_ERROR](#) to override the failure behavior if you have the language specified, regardless of the language's existence.

Syntax

```
Obj = OBJ_NEW( 'IDLffLangCat', Language [, PROPERTY=value]
              [, /CONTINUE_ON_ERROR] )
```

or

```
Result = Obj->[IDLffLangCat::]Init( Language [, PROPERTY=value]
                                   [, /CONTINUE_ON_ERROR] ) (In a lifecycle method only.)
```

Return Value

Returns the new object if successful or a null object otherwise if initialized with OBJ_NEW, or returns 1 if successful or 0 otherwise if called from a subclass's Init method.

Arguments

Language

A string containing the name of the language to load from the catalog.

Keywords

Any property listed under “[IDLffLangCat Properties](#)” on page 3420 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

You must specify either APP_NAME or FILENAME for this method. If APP_NAME is specified, it overrides any input to FILENAME.

CONTINUE_ON_ERROR

If set, the object will be created as long as the language is specified, regardless of the validity of any of the input parameters. If not set, the object will not be created if any input is invalid. If a language is not specified or is specified incorrectly (e.g., as a multiple element array), the object will not be created, and an error will be thrown, regardless of the value of this keyword.

Version History

6.1	Introduced
-----	------------

IDLffLangCat::Query

The IDLffLangCat::Query function method returns the string or string array that corresponds to all supplied key values.

Syntax

```
Result = Obj->[IDLffLangCat::]Query( Key [, DEFAULT_STRING=string] )
```

Return Value

Returns a string or string array that corresponds to all supplied key values. If no key can be found, then the default string or, if no default string is supplied, a null string is returned.

Arguments

Key

A string or string array used as the key or keys against which the query is performed. If a given key does not exist in the current language, the default language is queried (if one exists).

Keywords

DEFAULT_STRING

Set this keyword to a string or string array to be used if the key is not found in the catalog. If a scalar string is supplied, it will be returned for all keys not found. For example, if DEFAULT_STRING is “Key not found,” this string is returned for each failed query on a key or keys. If a string array is supplied, only those values whose indices match the missing keys will be returned. That is, you can have different default strings for different cases of failed query matches (e.g., “No File key found” and “No Tools key found” returned, respectively, for failed queries on keys associated with a File menu and a Tools menu).

Version History

6.1	Introduced
-----	------------

IDLffLangCat:: SetProperty

The IDLffLangCat::SetProperty procedure method sets the value of a property or group of properties for an IDLffLangCat object.

Syntax

Obj->[IDLffLangCat::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLffLangCat Properties” on page 3420 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.1	Introduced
-----	------------

IDLffMJPEG2000

The IDLffMJPEG2000 object provides the ability to read and write Motion JPEG2000 (MJ2) files. Motion JPEG2000, like JPEG2000, uses the Discrete Wavelet Transform (DWT) to compress files. This lossless compression option permits retrieval of the original data. With lossy compression, original data is lost during compression and cannot be recovered. DWT is an excellent compression scheme for continuous tone images such as geospatial and medical imagery.

A Motion JPEG2000 (MJ2) file contains a series of frames, each of which is an independent JPEG2000 image. An MJ2 animation displays a timed sequence of frames and uses *intra-frame* coding, which means each frame is an independent entity. In contrast, MPEG files typically use *inter-frame* encoding (motion estimation)—each frame is dependent on the previous frames. Because of the intra-frame encoding, MJ2 files can support lossless compression and permit random access to individual frames. These features make the Motion JPEG2000 file format ideal for scientific applications.

Each frame of an MJ2 file (like a JPEG2000 image) may consist of one or more components (color or data bands), tiles, or regions. Using the IDLffMJPEG2000 object, you can play an animation consisting of frames, components, tiles or regions and can create a file containing frames, components, and tiles. Additionally, you can specify the number of levels (image resolutions) and quality layers when creating or playing back an MJ2 file

An IDLffMJPEG2000 object permits reading or writing an MJ2 file (based on the [WRITE](#) property value). However, the same IDLffMJPEG2000 object cannot be used to both write and read an MJ2 file. You can write a file with one object (where `WRITE=1`), but you must create a separate object (where `WRITE=0`, the default) in order to read or play the new MJ2 file.

Note

The rate at which the IDLffMJPEG2000 object can compress or decompress frames is affected by the contents of the individual frames being compressed or decompressed and by the processing speed of your system. The amount of compression is dependent on the contents of the frames being compressed.

About Processing Threads

Internally, several IDLffMJPEG2000 methods make use of background processing threads that allow the user interface to stay more responsive while MJ2 file data is being compressed (written) or decompressed (read). On a dual processor or

multiprocessor machine the UI thread (of the main IDL process) and the background thread will typically run on separate processors allowing higher compression and decompression throughput. These threads are described in each method where appropriate.

Reading MJ2 Files

You can read or play a sequence of frames, components, tiles or regions contained in an existing MJ2 file or you can randomly access individual elements. Additionally, any element may be returned at a specified resolution (level) or quality (layer). For details on how to use the `IDLffMJPEG2000` object to read MJ2 files see [“Playing a Motion JPEG2000 Animation”](#) (Chapter 6, *Using IDL*).

Tip

You can view monochrome and RGB animations in the pre-built IDL Motion JPEG2000 Player. This example code, `mj2_player.pro`, and a sample image, `idl_mjpeg2000_example.mj2`, are located in the `IDL_DIR\examples\mjpeg2000` directory where `IDL_DIR` is the directory where you have installed IDL. If you have an MJPEG2000 codec installed, you can also play animations in other media players including the Windows Media Player.

Playback will occur as fast as the frames can be decompressed unless you implement some type of timer mechanism. See [“Controlling the Playback Rate”](#) (Chapter 6, *Using IDL*) for details.

Writing MJ2 Files

You can write (create) an MJ2 file that consists of frames, components and tiles, which contain the desired number of quality levels. An MJ2 file can store multiple related or non-related images (frames) as long as each frame has the same dimensions and same number of components. Files can be written in a lossless or lossy format depending on the value of the `REVERSIBLE` property.

The source of frame data for the animation can be existing images, generated images, or snapshots of an `IDLgrWindow` display. Regardless of the source, use the `SetData` method to write the data to the file, and the `Commit` method to close the processing thread once all of the frames have been added to the animation.

For an example that adds a series of `IDLgrWindow` screen captures to an MJ2 file, see the `mj2_writer_rgb.pro` example described below.

Depending on how you pass in data, you may need to set several properties prior to the first call to `SetData` in order to create the expected MJ2 file. For details on how to

use the `IDLffMJPEG2000` object to write MJ2 files, see “[Creating a Motion JPEG2000 Animation](#)” (Chapter 6, *Using IDL*).

Tip

You can use the example IDL Motion JPEG2000 Writer, `mj2_writer_rgb.pro`, as a template for creating an MJ2 animation. This example is located in the `IDL_DIR\examples\mjpeg2000` directory where `IDL_DIR` is the directory where you have installed IDL. Running the example creates a new MJ2 file, which is written to your application user directory, a subdirectory of your home directory.

Note

The `IDLffMJPEG2000` object supports reading and writing Motion JPEG2000 files stored in a progressive format. See the [SCAN_MODE](#) property for details.

Superclasses

None

Creation

See [IDLffMJPEG2000::Init](#).

Properties

Objects of this class have the following properties. See “[IDLffMJPEG2000 Properties](#)” on page 3438 for details on individual properties.

- [BIT_DEPTH](#)
- [BIT_RATE](#)
- [COLOR_SPACE](#)
- [COMMENT](#)
- [CURRENT_FRAME](#)
- [DIMENSIONS](#)
- [DURATION](#)
- [FILENAME](#)
- [FRAME_BUFFER_LENGTH](#)
- [N_LEVELS](#)
- [N_TILES](#)
- [PALETTE](#)
- [PROGRESSION](#)
- [REVERSIBLE](#)
- [SCAN_MODE](#)
- [SIGNED](#)
- [STATE](#)
- [TILE_DIMENSIONS](#)

- [FRAMES_IN_BUFFER](#)
- [FRAME_PERIOD](#)
- [N_COMPONENTS](#)
- [N_FRAMES](#)
- [N_LAYERS](#)
- [TIMESCALE](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

Methods

This class has the following methods:

[IDLffMJPEG2000::Cleanup](#)
[IDLffMJPEG2000::Commit](#)
[IDLffMJPEG2000::GetData](#)
[IDLffMJPEG2000::GetProperty](#)
[IDLffMJPEG2000::GetSequentialData](#)
[IDLffMJPEG2000::Init](#)
[IDLffMJPEG2000::ReleaseSequentialData](#)
[IDLffMJPEG2000::SetData](#)
[IDLffMJPEG2000::SetProperty](#)
[IDLffMJPEG2000::StartSequentialReading](#)
[IDLffMJPEG2000::StopSequentialReading](#)

Examples

The following simple example adds slices of data from an MRI of a human head to an MJ2 file to create a short animation. Each `SetData` call adds a single slice of data, resulting in an animation consisting of 57 frames.

Note

For additional examples, see [“Animations”](#) (Chapter 6, *Using IDL*).

```
PRO mj2_simple_write_read

; Read image data, which contains 57 slices.
nFrames = 57
head = READ_BINARY( FILEPATH('head.dat', $
```

```

SUBDIRECTORY=['examples','data']), $
DATA_DIMS=[80,100, 57])

; Enter new name for MJ2 file or select existing file
; to be overwritten.
file = DIALOG_PICKFILE(DEFAULT_EXTENSION="mj2", $
    TITLE="Enter Name for File")

; Create an IDLffMJPEG2000 object.
oMJ2write=OBJ_NEW('IDLffMJPEG2000', file, /WRITE, /REVERSIBLE)

; Write the data of each frame into the MJ2 file.
FOR i=0, nFrames-1 DO BEGIN
    data = head[*,* ,i]
    result = oMJ2write->SetData(data)
ENDFOR

; Commit and close the IDLffMJPEG2000 object.
return = oMJ2write->Commit(10000)
OBJ_DESTROY, oMJ2write

; Create a new IDLffMJPEG2000 object to read the MJ2 file.
oMJ2read=OBJ_NEW("IDLffMJPEG2000", file)
oMJ2read->GetProperty,N_FRAMES=nFrames, DIMENSIONS=dims

; Create a window and display simple animation.
WINDOW, 0, XSIZE=2*dims[0], YSIZE=2*dims[1]

FOR i=0, nFrames-1 DO BEGIN
    ; Return data and display magnified version. Use WAIT to
    ; pause between each frame for visibility. Unless a timer
    ; is used in conjunction with the FRAME_PERIOD and
    ; TIMESCALE properties, the default playback rate will be
    ; as fast as the frames can be decompressed.
    data = oMJ2read->GetData(i)
    TVSCL, CONGRID(data, 2*dims[0], 2*dims[1])
    WAIT, 0.1
ENDFOR

; Cleanup.
OBJ_DESTROY, oMJ2read

End

```

IDLffMJPEG2000 Properties

IDLffMJPEG2000 objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffMJPEG2000::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffMJPEG2000::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffMJPEG2000::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties:

- [BIT_DEPTH](#)
- [BIT_RATE](#)
- [COLOR_SPACE](#)
- [COMMENT](#)
- [CURRENT_FRAME](#)
- [DIMENSIONS](#)
- [DURATION](#)
- [FILENAME](#)
- [FRAME_BUFFER_LENGTH](#)
- [FRAMES_IN_BUFFER](#)
- [FRAME_PERIOD](#)
- [N_COMPONENTS](#)
- [N_FRAMES](#)
- [N_LAYERS](#)
- [N_LEVELS](#)
- [N_TILES](#)
- [PALETTE](#)
- [PROGRESSION](#)
- [REVERSIBLE](#)
- [SCAN_MODE](#)
- [SIGNED](#)
- [STATE](#)
- [TILE_DIMENSIONS](#)
- [TIMESCALE](#)
- [WRITE](#)
- [XML](#)
- [YCC](#)

BIT_DEPTH

An integer value between 1 and 24 that indicates the bit depth of a file component. All components in the file must have the same bit depth. For example, RGB frames have a bit depth of 8 bits, so this property would be set to 8.

This property must be set prior to the first call to `IDLffMJPEG2000::SetData`. The default value is 8 bits.

Note

When writing a MJPEG2000 file, the default `BIT_DEPTH` is 8 regardless of the data type supplied to `SetData`. If you are writing out short or long integer data, you must set `BIT_DEPTH` to the correct value for the data type.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

You can set this property only for an MJ2 file that is open for writing (`WRITE=1`).

BIT_RATE

A floating-point vector specifying the bit rate for each layer. The `BIT_RATE` vector, if set, is used by the compression engine when writing files to control the size of each layer. The compression engine will compress each layer into the number of bytes calculated from the bit rate for the layer. If the bit rate is not set, the compression engine automatically calculates the number of bytes that will be used to store a layer.

The number of vector elements must be equal to one of the following:

- The number of quality layers (the `N_LAYERS` property value) — each vector element applies to one quality layer. The values may be given in any order and will be automatically sorted into ascending order.
- Two elements — the bit rates applied to each quality layer will be approximately logarithmically spaced between the two vector values.

A value of -1 anywhere within the `BIT_RATE` vector indicates that the highest quality layer should include all compressed bits. When the `REVERSIBLE` property is true, the last rate will be automatically set to -1 to ensure that the last layer contains the bits needed to recreate the original frame data.

An error will be thrown if the number of vector elements exceeds the number of layers. The value in the `N_LAYERS` property must always be equal to or greater than

the number of vector elements in the BIT_RATE property (unless there are two elements).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

COLOR_SPACE

A string identifying the color space of the MJ2 file. Allowable values are:

Value	Description
sLUM	The luminance (monochrome) space.
sRGB	The red, green, blue color space — a reasonably good model for color imagery which has been corrected for display on a monitor.
sYCC	<p>A three-component color space derived by applying the standard YCbCr color transform to RGB data — the YCbCr transform is identical to the irreversible color transform defined by JPEG2000 at the code stream level.</p> <p>This property can be set to sYCC when you are writing RGB data and the YCC property is set to 1 (true).</p> <p>Note - Some players and codecs expect this COLOR_SPACE property to be set to sRGB even when the frames were compressed using YCC.</p>

When writing a file, this property must be set prior to the first call to [IDLffMJPEG2000::SetData](#) in order to take effect. A value set to this property before calling SetData is always honored. If you do not set this property before calling SetData, the property value will be automatically set based on the dimensions of the data passed to SetData as follows:

SetData Data Characteristics	Resulting COLOR_SPACE
Number of frame components equals 3	sRGB
PALETTE property has been set	
Number of frame components not equal to 3	sLUM

Note

If you are writing 3-band monochrome data, you must set `COLOR_SPACE` to `sLUM` prior to the first call to `SetData`.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COMMENT

A string providing a descriptive comment for the MJ2 file. When writing a file, this property must be set prior to the first call to `IDLffMJPEG2000::SetData`. The maximum length is 65,534 characters.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CURRENT_FRAME

A long value that contains the frame number of the last frame compressed (in a file open for writing) or decompressed (in a file open for reading).

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DIMENSIONS

A two element array giving the dimensions [*width*, *height*] of a frame.

In a file that is open for writing (`WRITE=1`), this property must be set prior to the first call to `IDLffMJPEG2000::SetData` in order to take effect. If you call `SetData`

before specifying this property, the DIMENSIONS property value will be automatically set based on the dimensions of the data passed to SetData.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Regardless of whether the DIMENSIONS property is set before the first call to SetData or is set by default based on data dimensions, each subsequent data array must have dimensions identical to that which has been set in order to avoid a SetData error.

DURATION

A floating-point value that returns the length of a movie in seconds. When reading an MJ2 file, this property comes from the file. When writing an MJ2 file, this property is automatically calculated and set in the MJ2 file based on the number of frames written and the [TIMESCALE](#) property value.

Property Type	Float		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

FILENAME

A string that specifies the full path and name of the file associated with the MJ2 file being read or written. The property can only be set as the *Filename* argument during IDLffMJPEG2000 object creation. See the [IDLffMJPEG2000::Init](#) method for details.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

FRAME_BUFFER_LENGTH

A long value that specifies the number of frames that can be held in the frame buffer when doing a sequential playback or when writing an MJ2 file. This property is used by the background read or write processing thread. You can change this property

value to enable high speed MJ2 file playback and creation as described in “[High Speed MJ2 Reading and Writing](#)” (Chapter 6, *Using IDL*).

This property must be set prior to calling `IDLffMJPEG2000::StartSequentialReading` when reading a file, or prior to the first call to `IDLffMJPEG2000::SetData` when writing a file. If this property is not set then the default value of 3 is used.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FRAMES_IN_BUFFER

A long value that returns the number of frames in the read or write frame buffer. When sequentially reading an MJ2 file, this property indicates the number of decompressed frames currently available in the frame buffer. When writing an MJ2 file, this property indicates the number of frames in the write frame buffer waiting to be compressed by the processing thread.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

FRAME_PERIOD

A long value indicating the duration of a frame in ticks, which in conjunction with the [TIMESCALE](#) property, determines the playback rate. See “[Computing Playback Rate](#)” on page 3444 for details.

When this property is set, it is applied to the current frame and every subsequent frame in an MJ2 file unless it is overridden by the `IDLffMJPEG2000::SetData` `FRAME_PERIOD` keyword. When retrieving this property, it returns the frame period of the first frame in the file (when a file is first opened for reading) or the frame period of the current frame that is being read or written.

MJ2 players will typically attempt to playback the frames using the `FRAME_PERIOD` property. However, the actual playback rate may be slower than the desired rate if it exceeds the rate at which the MJ2 player can actually decompress and display frames.

The default FRAME_PERIOD value is 1000.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

You should always append the value you set with “L” to ensure it is interpreted as a long value. For example, use FRAME_PERIOD=2000L.

Computing Playback Rate

To compute the playback rate, divide the FRAME_PERIOD value by the [TIMESCALE](#) property value. Take 1 (frame) over this value (seconds per frame) to get the number of frames per second. For example, the default FRAME_PERIOD (1000) and TIMESCALE (30,000) translate into a playback rate of approximately 30 frames per second:

$$\frac{1000\text{ticks}}{1\text{frame}} \times \frac{1\text{s}}{30000\text{ticks}} = 0.033\text{s/frame}$$

$$\frac{1\text{frame}}{0.033\text{s/frame}} \approx 30\text{frames/s}$$

Leaving the TIMESCALE property value unchanged, you can change the FRAME_PERIOD rate to control playback speed. A smaller FRAME_PERIOD rate speeds up playback; a larger FRAME_PERIOD rate slows playback.

Note

See “[Controlling the Playback Rate](#)” (Chapter 6, *Using IDL*) for details and examples.

N_COMPONENTS

A long value that indicates the number of components (also known as bands or channels) in a frame.

When writing a file, this property must be set prior to the first call to [IDLffMJPEG2000::SetData](#) in order to take effect. If you call SetData before

specifying this property, the `N_COMPONENTS` property value will be automatically set based on the number of components in the first frame of data passed to `SetData`.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_FRAMES

A long value that returns the number of frames in the file. This is either the total number of frames (in a file that is being read), or the number of frames added to the file prior to requesting this property (in a file that is being written).

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_LAYERS

A long value that indicates the number of quality layers used to build each frame. Possible values range from 1 to 244. Each layer contains the information required to represent the frame at a higher quality, given the information from all the previous layers. When a frame has more than one layer, the previous layers are used to build the frame at the requested layer value.

When writing an MJ2 file:

- If `N_LAYERS` is greater than one and the `BIT_RATE` property is not set, the layers will be assigned roughly logarithmically-spaced bit rates
- If `N_LAYERS` is greater than one and the `BIT_RATE` property has been set, the `BIT_RATE` property vector governs the number of bytes allocated to each layer
- If the `REVERSIBLE` property is true, then the last layer, in conjunction with the previous layers (if there are any), will produce a lossless frame

Suppose you have specified 3 layers. The first layer will undergo the greatest compression and be of the lowest quality. Successive layers will be less compressed and contain more clarity. If the `REVERSIBLE` property is set, the last layer will be equivalent to the original data.

This property must be set prior to the first call to [IDLffMJPEG2000::SetData](#) to take effect. If it is not set before calling `SetData`, the property will be set to the default value, 1. The largest possible value is 244.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

When you are playing an MJ2 animation, you can set the `MAX_LAYERS` keyword to [IDLffMJPEG2000::StartSequentialReading](#) or [IDLffMJPEG2000::GetData](#) to control what quality layers will be displayed.

N_LEVELS

An integer that specifies the number of wavelet decomposition (resolution) levels, or stages, in the range of 0...15 where a value of zero indicates no wavelet transform (the full resolution image). For instance, if you have a 1024 by 1024 pixel image, the resolution of each successive level is half of the width and height of the preceding one:

level 0	1024 by 1024
level 1	512 by 512
level 2	256 by 256

Tip

This level/resolution scheme is similar to image pyramids. See “[Image Pyramids](#)” (Chapter 4, *Object Programming*) for a visual representation.

If this property is not set prior to the first call to [IDLffMJPEG2000::SetData](#) then this property will be automatically set to the default value. If the [PALETTE](#) property has been set, the default value is 0. Otherwise, the default value is 5.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

When you are playing an MJ2 animation, you can set the DISCARD_LEVELS keyword to [IDLffMJPEG2000::StartSequentialReading](#) or [IDLffMJPEG2000::GetData](#) to control what level of data will be displayed.

N_TILES

A long value that returns the number of tiles in a component.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PALETTE

A byte or integer array that specifies the red, green, and blue values of the color lookup table to be associated with the color indices found in the frame. An MJ2 file that contains a palette (also known as a color table) stores frames that have only a single component consisting of the color indices.

If reading a file that contains a palette, this property will return an n -by- m array of byte or integer values, where n is the number of intensity values, and m is the number of lookup tables (m is usually 3, indicating red, green, and blue). If the file does not have a palette, this property will return a scalar zero.

When writing an MJ2 file, set this property to a 3-by- n or an n -by-3 array of byte or integer values, where n is the number of intensity values for the three color channels of red, green, and blue. The value n must be a power of 2 and ≤ 256 .

This property must be set prior to the first call to [IDLffMJPEG2000::SetData](#) if it is to be used.

Note

The default values of several properties depend upon the presence of a palette. When a palette is specified, [N_LEVELS](#)=0, [REVERSIBLE](#)=1, and [YCC](#)=0 are set by default.

Property Type	Byte or integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROGRESSION

A string defining the progression order. Progression order may be LRCP, RLCP, RPCL, PCRL, or CPRL where the progression identifiers are L = layer, R = resolution, C = component, and P = position. The four progression identifiers have the following interpretations:

Value	Meaning
L	Layer — a series of one or more quality layers, each contributing a quality increment for the entire frame at full resolution. The quality layers may be interpreted as sub-bitplanes containing the frame data at a specified, possibly fractional, bit-rate.
R	Resolution — each resolution level of a frame, which corresponds to the <code>N_LEVELS</code> keyword used in encoding, and can be considered to contain the frame data at a given size or resolution. Each level adds another level of detail to the previous levels.
C	Component — each frame component of the above.
P	Position — each position (tile) within the frame component.

Data is written to the output file iteratively over the four progression identifiers in this property string—that is, the output is written in four nested iteration levels. The first character refers to the outermost level of the iteration, while the last refers to the innermost level. For example, “LRCP” means that an image is encoded as shown in the preceding table, with quality being the outermost loop.

In the following PCRL example, if a frame consists of 2 quality layers, 5 resolution levels, 3 components, and 16 positions or tiles, the frame would be encoded in a series of packets as follows:

```
P0C0R0L0, P1C0R0L0, P2C0R0L0, ..., P15C0R0L0
P0C1R0L0, P1C1R0L0, P2C1R0L0, ..., P15C1R0L0
P0C2R0L0, P1C2R0L0, P2C2R0L0, ..., P15C2R0L0
P0C0R1L0, P1C0R1L0, P2C0R1L0, ..., P15C0R1L0
P0C1R1L0, P1C1R1L0, P2C1R1L0, ..., P15C1R1L0
```

```

POC2R1L0, P1C2R1L0, P2C2R1L0, ..., P15C2R1L0
... ..
... ..
... ..
POC2R4L0, P1C2R4L0, P2C2R4L0, ..., P15C2R4L0

POC0R0L1, P1C0R0L1, P2C0R0L1, ..., P15C0R0L1
POC1R0L1, P1C1R0L1, P2C1R0L1, ..., P15C1R0L1
POC2R0L1, P1C2R0L1, P2C2R0L1, ..., P15C2R0L1

```

This encodes all components over the entire frame at a given quality level before sending the next quality refinement.

Note

When encoding a large frame with a large number of components, memory requirements will be minimized by sending each component by means of a separate call to `SetData`, and by using a progression order of CPRL.

Note

When writing frames with multiple components and the number of layers is greater than one, the progression order can be set to RPCL, PCRL, CPRL. The LRCP and RLCP progression orders are not usable in this case.

This property is ignored when MJ2 files are being read. The default value is LRCP.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REVERSIBLE

A Boolean value that specifies whether or not you can get the original JP2 data from an MJ2 frame as follows:

0	Frames are irreversible (lossy). The default.
1	Frames are reversible (lossless).

Typically, it will be faster to compress and decompress lossy frames, but this is dependent upon image content.

To create reversible (lossless) frames, you must set this property to 1 prior to the first call to `IDLffMJPEG2000::SetData`. If the `PALETTE` property is set, this property is

automatically set to 1 (reversible, lossless frames). If you have not set the PALETTE property, and you call SetData before setting this property, it will be set to the default value, 0 (irreversible, lossy frames).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SCAN_MODE

A long value that returns whether a frame is stored in a progressive format or in an interlaced format.

Note

The IDLffMJPEG2000 object only supports the progressive format—this object can only read and write MJ2 files in the progressive format.

In the progressive format, all the rows are returned or set in one call. In the interlaced format (not supported), the even rows are returned in one call and the odd rows are returned in the next call. Possible values are:

0	Progressive (supported)
1	Interlaced with the top row first (not supported)
2	Interlaced with the bottom row first (not supported)

The default value is 0 and cannot be set.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SIGNED

A long value that indicates whether the frame data is signed or unsigned as follows:

0	Unsigned frame data (the default)
1	Signed frame data

If `IDLffMJPEG2000::SetData` is called before setting this property, it will be set to the default value, 0.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STATE

A long value that returns whether or not a background read or write processing thread is currently running. Possible values are:

0	Background thread is idle
Non-zero	Background thread is running

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

TILE_DIMENSIONS

A two-element vector indicating the [*width, height*] of each tile. If a frame component contains only one tile, this property will be automatically set to the [DIMENSIONS](#) of the frame.

When writing frame component(s) with more than one tile, this property must be set prior to the first call to `IDLffMJPEG2000::SetData`.

Property Type	Long vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TIMESCALE

This property indicates the number of ticks in a second. This property, in conjunction with the [FRAME_PERIOD](#) period property, controls the playback rate. See [“Computing Playback Rate”](#) on page 3444 for details.

The default value is 30,000.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

WRITE

A Boolean value that indicates whether a file is open for reading or writing as follows:

0	File is read-only (the default)
1	File is open for writing

This property can only be set during initialization (see [IDLffMJPEG2000::Init](#)) or retrieved.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

XML

A string vector, with each element containing the XML string of a corresponding MJ2 XML box. When creating a MJ2 file, call this property with a string value to add the corresponding XML to the MJ2 file. This property can be set multiple times. Each time it is set, the corresponding string will be added to a separate XML box.

When reading a MJ2 file, if the file does not contain any XML boxes, the property returns a null string. If the file contains a single XML box, the property will return a single string containing the entire contents of the XML box. If the file contains multiple XML boxes, the property will return an array of strings, each containing the contents of an entire XML box

This keyword is only valid for MJ2 files.

Here are a few tips for working with XML in MJ2 files and IDLffMJPEG2000 objects:

- An XML box can hold plain text as well as XML text.

- There can be multiple XML boxes in MJ2 files. For example, in a MJ2 file, you could add an XML box for each frame.
- To parse the MJ2 file XML tag with the IDL SAX parser, read the XML tag and store the XML string in a variable. You can then parse the variable directly with the `IDLffXMLSAX::ParseFile` method.
- To parse the MJ2 file XML tag with the IDL DOM parser, read the XML tag and save the XML string in a temporary file. You can then pass the file to `IDLffXMLDOMDocument`.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCC

A Boolean value indicating whether a frame (that consists of 3 components) has or should undergo conversion from the RGB to the YCC Luminance-Chrominance color space as follows:

- **When reading a file:**

0 (false)	Data was not originally converted from the RGB color space to the YCC color space.
1 (true)	Data was converted from the RGB color space to the YCC color space. Consider returning all three frame components when calling <code>IDLffMJPEG2000::GetData</code> or <code>IDLffMJPEG2000::StartSequentialReading</code> so that the YCC data can be correctly transformed back to the RGB color space.

- **When writing a file:**

0 (false)	Data should not be converted from the RGB color space to the YCC color space. When a PALETTE has been specified, YCC is automatically set to 0.
1 (true)	Convert RGB data to YCrCb. This is the default for a frame that has 3 components. The RGB components are automatically converted to YCrCb, and then written. Note - For the RGB-to-YCC conversion to occur, all three components must be provided at the same time. If the components are provided in separate calls to IDLffMJPEG2000::SetData , the YCC conversion is not performed.

Note

The default action that converts RGB to YCC when writing a file may be overridden by explicitly setting YCC to zero.

If the frame being written does not have three components, this property is ignored.

Transforming the color coordinates from RGB to YCC decorrelates the three color components and improves both compression and decompression performance for RGB frames. MJPEG2000 readers will then convert frame data back to RGB. The default value is 1 except as noted above.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffMJPEG2000::Cleanup

The IDLffMJPEG2000::Cleanup procedure method performs all cleanup operations on the Motion JPEG2000 object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffMJPEG2000::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::Commit

The IDLffMJPEG2000::Commit method shuts down the background processing thread and closes the MJ2 file that is being written. Although the MJ2 file does exist on disk, it cannot be accessed until this method successfully returns.

Note

The same IDLffMJPEG2000 object cannot be used to both write and read an MJ2 file. You can write a file with one object (where WRITE=1), but you must create a separate object (where WRITE=0, the default) in order to play the new MJ2 file.

The *Wait* argument provides time for the processing thread to finish compressing any images queued in the write frame buffer. The Commit call will return when the frame buffer is empty or when the wait period expires.

Tip

The [FRAMES_IN_BUFFER](#) property can be used to determine the current number of frames in the frame buffer.

When writing frames on a component-by-component basis or tile-by-tile basis, the frame must be completed prior to calling Commit. If the last frame being written is not complete (does not have all the needed components and or tiles to make a complete frame) when Commit is called, the method will throw an error and the file will not be closed. This method will throw an error if the commit fails. A CATCH statement can be used to trap these errors.

Syntax

Result = *Obj*->[IDLffMJPEG2000::]Commit(*Wait*)

Return Value

The return value indicates the state of the MJ2 file when it was committed to disk:

0	Failure. The file is not usable.
1	Success. The file has been created with all available frames in the frame buffer.
2	Wait period expired before the frame buffer was empty. The file has been created but may not contain all the frames passed in via the IDLffMJPEG2000::SetData method.

Arguments

Wait

A long, positive value specifying the number of milliseconds to wait for the frame buffer to become empty. For example, set the *Wait* argument to 10,000 in order to wait up to 10 seconds for the background processing thread to finish compressing all the remaining frames in the frame buffer before the *Commit* method is called. Regardless of the *Wait* argument, the *Commit* method will return as soon as the frame buffer is empty. If the wait period expires before all of the frames in the frame buffer can be compressed, the return value will be 2.

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::GetData

The IDLffMJPEG2000::GetData function method returns data for a specified frame (or component, tile or region of a frame) from an MJ2 file. This method does not return until the requested data has been decompressed. It will throw an error if the decompression fails. A CATCH statement can be used to trap such an error.

To playback a large number of frames in a sequential manner, consider using the StartSequentialReading method, which includes a built-in background processing thread for file decompression. See [“Sequential Motion JPEG2000 Playback”](#) (Chapter 6, *Using IDL*), which describes using the StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods with a timer mechanism to create a sequential playback.

Note

You can use the WAIT procedure, a widget timer, or a IDLitWindow timer mechanism to control the rate at which random frames are retrieved if needed.

Note

If **PERSISTENT** = 0 (*the default*) when the IDLffMJPEG2000 object was created, only one GetData call can be made per frame when reading individual components, tiles or regions. PERSISTENT must be set on Init in order to access tiled data.

Syntax

```
Result = Obj->[IDLffMJPEG2000::]GetData(FrameNumber
    [, COMPONENT=value] [, DISCARD_LEVELS=value]
    [, MAX_LAYERS=value] [, N_COMPONENTS=value] [, /ORDER]
    [, REGION=value] [, /RGB] [, TILE_INDEX=value])
```

Return Value

Returns a two- or three-dimensional array containing the frame data that corresponds to the specified frame number. The exact dimensions are based on keyword values:

Keyword	Condition and Result
RGB	Set —array dimensions are [3, <i>width</i> , <i>height</i>].
	<p>Not set—array dimensions are [<i>nComponents</i>, <i>width</i>, <i>height</i>] where <i>nComponents</i>, the number of bands or channels of data, depends on the COMPONENT and N_COMPONENTS keyword settings.</p> <p>If COMPONENT is not set, <i>nComponents</i> equals the number of components in the frame.</p> <p>If a starting COMPONENT is set, <i>nComponents</i> equals the number of components requested in N_COMPONENTS unless the frame has only one component. In this case the array dimensions are [<i>width</i>, <i>height</i>]. If a starting COMPONENT is set, but N_COMPONENTS is not set, <i>nComponents</i> equals all available components from the starting component.</p>
REGION	If set, the array <i>width</i> and <i>height</i> are determined by the <i>width</i> and <i>height</i> values in the 4-element REGION vector [<i>startX</i> , <i>startY</i> , <i>width</i> , <i>height</i>].
TILE_INDEX	If set, the array <i>width</i> and <i>height</i> equal the dimensions of a single tile, defined in the TILE_DIMENSIONS property value.

The data type of the result is automatically determined using the **BIT_DEPTH** and **SIGNED** properties of the returned components as follows;

Data Properties	Result
BIT_DEPTH ≤ 8 or RGB is set	Byte
BIT_DEPTH ≥ 9 or ≤ 16	Integer or unsigned integer
BIT_DEPTH > 16	Long or unsigned long

Note

All components in the MJ2 file must have the same bit depth and be either signed or unsigned. Components with different bit depths or a mixture of signed and unsigned data are not supported.

Arguments

FrameNumber

A long value specifying the number of the frame from which data is to be retrieved. Allowable values range from 0 to the total number of frames (the `N_FRAMES` property value) - 1.

Keywords

COMPONENT

An integer value indicating the zero-based index number of the first component to be returned. The total number of components returned depends upon this keyword and the value of `N_COMPONENTS` as follows:

- This keyword is set and `N_COMPONENTS` is not set — returns all the components from the starting COMPONENT
- This keyword is set and `N_COMPONENTS` is set — returns the number of components specified by `N_COMPONENTS` from the starting COMPONENT

If this keyword is not set, all the components are returned. The default is 0.

DISCARD_LEVELS

An integer value specifying the number of resolution levels to be excluded from the result starting with the highest resolution level. For example, given a full-resolution frame that is 1024 by 1024 pixels:

Value	Description
0	The default. No data is discarded.
1	Discard 1 level, the highest resolution data (e.g. discard the 1024 by 1024 level, leaving the 512 by 512 data).
2	Discard 2 levels of data (e.g. discard the 1024 by 1024 and 512 by 512 levels, leaving the 256 by 256 data).

Determine the number of resolution levels by checking the [N_LEVELS](#) property.

MAX_LAYERS

An integer value specifying the maximum number of quality layers to be read. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, means all available layers should be returned. If `MAX_LAYERS` is 3, data from the first, second and third quality layers will be combined in the returned data. Determine the number of quality layers in a file by checking the value of the [N_LAYERS](#) property.

N_COMPONENTS

An integer value specifying the number of components to return from the starting component specified by the [COMPONENT](#) keyword. If this keyword is set, but `COMPONENT` is not set, the default `COMPONENT` value (0) will be used.

ORDER

An integer value specifying the order in which to return data. Motion JPEG2000 frames are assumed to be stored in top-to-bottom order, while IDL usually assumes frames are in bottom-to-top order. By default (`ORDER=0`), this method will automatically flip the result to match IDL's bottom-to-top order. Setting `ORDER` to a nonzero value will return the Motion JPEG2000 frames without doing the vertical flip.

REGION

A four-element long vector containing the rectangular region of the frame to read. The region is specified as [*startX*, *startY*, *width*, *height*], where *startX* and *startY* must be in the range 0 ... $2^{32}-2$, and *width* and *height* must be in the range 1 ... $2^{32}-1$. The region must contain at least some portion of the frame, or an error will occur. If the region is larger than the frame, or extends beyond the frame, only the portion that lies within the frame will be returned. This keyword, in combination with the [COMPONENT](#) keyword, lets you access any region from a particular component.

RGB

If set, the resulting data stream will be interpreted as RGB frames. The returned array will always have three components (red, green, and blue) with the dimensions [*3*, *width*, *height*]. See the following table for information on what data will be read if fewer than or more than 3 components are specified, or if the keyword is not set.

Note

The Motion JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the [YCC](#) property.

RGB Set?	Number of Components	Outcome
Yes	More than 3	Only the first three components are returned.
	Less than 3	An error is thrown.

RGB Set?	Number of Components	Outcome
No	3	If a color transformation has been applied to the input stream, the three components, which are encoded as YCC , will automatically be converted to RGB. To avoid this conversion you must transfer more than or fewer than three components when using <code>GetData</code> .
	Not equal to 3	Each component in the data stream will be placed in the result without interpretation. Result will have dimensions: <code>[N_COMPONENTS, width, height]</code> .

You cannot specify **RGB** and **COMPONENT** or **N_COMPONENTS** at the same time. An error will be thrown in such cases.

TILE_INDEX

An integer value specifying the index of the tile to return. Tiles are numbered in raster scan fashion (from left to right starting at the top-left corner) starting with 0. This keyword, in combination with the **COMPONENT** keyword, lets you access any tile from a particular component. When this keyword is set, the **REGION** keyword is ignored.

IDLffMJPEG2000::GetProperty

The IDLffMJPEG2000::GetProperty procedure method retrieves a property or group of properties for an IDLffMJPEG2000 object.

Syntax

Obj->[IDLffMJPEG2000::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLffMJPEG2000 Properties](#)” on page 3438 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::GetSequentialData

The IDLffMJPEG::GetSequentialData function method returns the frame index number and retrieves the associated frame data from the frame buffer. The StartSequentialReading method, which loads data into the frame buffer, must be called before calling this method.

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are used with a timer mechanism to create a sequential playback as described in “[Sequential Motion JPEG2000 Playback](#)” (Chapter 6, *Using IDL*).

Note

Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback methods as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if retrieval fails. A CATCH statement can be used to trap these errors.

Syntax

```
Result = Obj->[IDLffMJPEG2000::]GetSequentialData( Data  
    [, FRAME_NUMBER=variable] [, FRAME_PERIOD=value] [, STEP=value] )
```

Return Value

If frame data is available in the frame buffer, the method returns a long value indicating the frame buffer index value. This index value is then used by the ReleaseSequentialData call to release the frame.

If no frame data is available, the return index value is -1. This indicates data is being read faster than it is being decompressed. See “[High Speed Sequential Playback](#)” (Chapter 6, *Using IDL*) for ways to avoid this problem.

Arguments

Data

If data is available, the *Data* variable will contain a two- or three-dimensional array associated with the returned frame index value. This data is essentially a pointer to a

slot in the frame buffer, and *not* a copy of the frame data. You should not attempt to modify this data as it is automatically freed when the `ReleaseSequentialData` method is called.

The array dimensions depend upon `IDLffMJPEG2000::StartSequentialReading` method keywords as follows:

Keyword	Result
RGB	RGB is set —array dimensions are [3, <i>width</i> , <i>height</i>].
	<p>RGB is not set—array dimensions are [<i>nComponents</i>, <i>width</i>, <i>height</i>] where <i>nComponents</i>, the number of bands or channels of data, depends on the <code>COMPONENT</code> and <code>N_COMPONENTS</code> keyword settings.</p> <p>If a starting <code>COMPONENT</code> is set, <i>nComponents</i> equals the value specified in <code>N_COMPONENTS</code> unless <code>N_COMPONENTS=1</code>. In this case the array dimensions are [<i>Width</i>, <i>Height</i>].</p> <p>If a starting <code>COMPONENT</code> is set, but <code>N_COMPONENTS</code> is not set, <i>nComponents</i> equals all available components from the starting component.</p> <p>If a starting <code>COMPONENT</code> is not set, then <i>nComponents</i> equals all available components.</p>
REGION	REGION is set —the array <i>width</i> and <i>height</i> are determined by the <i>width</i> and <i>height</i> values in the 4-element <code>REGION</code> vector [<i>startX</i> , <i>startY</i> , <i>width</i> , <i>height</i>].
TILE_INDEX	TILE_INDEX is set —the array <i>width</i> and <i>height</i> values equal the dimensions of a single tile, as defined in the <code>TILE_DIMENSIONS</code> property.

The data type of the result is automatically determined using the `BIT_DEPTH` and `SIGNED` properties of the returned components as follows:

Data Properties	Result
<code>BIT_DEPTH</code> ≤ 8 or <code>RGB</code> is set	Byte
<code>BIT_DEPTH</code> ≥ 9 or ≤ 16	Integer or unsigned integer
<code>BIT_DEPTH</code> > 16	Long or unsigned long

Note

All components in the MJ2 file must have the same bit depth and be either signed or unsigned. Components with different bit depths or a mixture of signed and unsigned data are not supported.

Keywords

FRAME_NUMBER

A variable that will contain the long frame number of the frame that GetSequentialData is currently accessing.

FRAME_PERIOD

A long value specifying the duration of a frame in ticks. Each frame in an MJ2 file can have a unique frame period, which lets you display individual frames for different lengths of time. The FRAME_PERIOD acts in conjunction with the TIMESCALE property to determine the playback rate. See [“Computing Playback Rate”](#) on page 3444 for details.

STEP

A long value indicating the number of frames to skip when retrieving frames from the frame buffer as follows:

Value	Description
0	Reads the next sequential frame (the default)
Positive value	Indicates the number of frames to skip when reading frames in the forward direction
Negative value	Indicates the number of frames to skip when reading frames in the reverse direction

Note

This keyword is intended to be used for manually stepping through frames when sequential playback is paused. This keyword should not be used to skip frames during continuous playback.

If the STEP value results in a frame request that is beyond the range of values defined by [IDLffMJPEG2000::StartSequentialReading](#) START_FRAME and STOP_FRAME keywords, the request will wrap to return the appropriate frame.

Examples

The following simple program uses the four sequential playback methods: StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading to display a sample MJ2 animation.

Note

In this example, the playback speed is equal to the frame rate calculated for the first frame. A more sophisticated example would handle varying frame rates. See [“Controlling the Playback Rate”](#) (Chapter 6, *Using IDL*) for more information and an additional example.

Run the example procedure by entering `mj2_simple_sequential_doc` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT mj2_simple_sequential_doc.pro`.

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::Init

The IDLffMJPEG2000::Init method initializes an IDLffMJPEG2000 object. When **WRITE** is not set or set equal to 0 (the default), the newly created Motion JPEG2000 object can be used to read (decode) frame data from a Motion JPEG2000 (MJ2) frame file. When **WRITE** is set or equal to one, the object can be used to create (encode) frame data to a Motion JPEG2000 file.

Note

When reading an MJ2 file that contains tiled data, you must set the **PERSISTENT** keyword to true in order to access tiles of data from an MJ2 file.

Syntax

```
Obj = OBJ_NEW( 'IDLffMJPEG2000', Filename [, /PERSISTENT]
              [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLffMJPEG2000::]Init( Filename [, /PERSISTENT]
                                     [, PROPERTY=value] ) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A string value that specifies the full path and name of the file associated with the MJ2 file being read or written, based on the **WRITE** property value as follows:

WRITE = 0	The file is opened for reading and cannot be modified.
WRITE = 1	The file is opened for writing. If an existing filename is given, the file contents will be overwritten without prompting.

Motion JPEG2000 files typically have a .mj2 extension, which is recognized by Motion JPEG2000 players. However, this object does not restrict or set the file extension, so it will reflect the value set in this *Filename* argument.

Keywords

In addition to the following keyword, any property listed under “[IDLffMJPEG2000 Properties](#)” on page 3438 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

PERSISTENT

A Boolean value that specifies whether or not data can be accessed more than a single time as follows:

0	Do not persist data. Minimize memory usage and limit certain types of data access to a single time. The default.
1	Persist data. Allow access to data multiple times and do not minimize memory usage. Note - You must set PERSISTENT to 1 if you want to access tiles from an MJ2 file.

The default value is 0.

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::ReleaseSequentialData

The IDLffMJPEG2000::ReleaseSequentialData procedure method releases a frame from the frame buffer during animation playback. After calling GetSequentialData, which reads the frame from the frame buffer, call this method to release the frame and make the frame buffer slot available to the next frame being decompressed.

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are typically used with a timer mechanism to create a sequential playback as described in “[Sequential Motion JPEG2000 Playback](#)” (Chapter 6, *Using IDL*).

Note

Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback methods as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if the release fails. A CATCH statement can be used to trap these errors.

Syntax

Obj->[IDLffMJPEG2000::]ReleaseSequentialData, *Frame_Index*

Arguments

Frame_Index

This long value is typically returned by the IDLffMJPEG2000::GetSequentialData method. If the *Frame_Index* is -1, it is ignored. If the *Frame_Index* is less than 0 or greater than the FRAME_BUFFER_LENGTH property, it is ignored.

Keywords

None

Examples

See the section of IDLffMJPEG2000::GetSequentialData for a simple example that uses the four sequential playback methods.

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::SetData

The IDLffMJPEG::SetData function method starts a background processing thread and adds frame data to an MJ2 file that is being created. Each call to SetData call adds a frame to the frame buffer, which will be compressed by the processing thread. The length of the frame buffer is determined by the `FRAME_BUFFER_LENGTH` property.

If SetData is called faster than the background processing thread can compress the frame data, SetData will wait for an available frame buffer slot before returning. To avoid such delays, see “[High Speed MJ2 Reading and Writing](#)” (Chapter 6, *Using IDL*) for options.

The SetData and `IDLffMJPEG2000::Commit` methods are used together to create a new file. After adding all of the data to the MJ2 file using SetData, call Commit to close the file and shut down the processing thread. For a full description of creating a new file see “[Creating a Motion JPEG2000 Animation](#)” (Chapter 6, *Using IDL*). You can playback the new MJ2 file by creating a new Motion JPEG2000 object that opens the file for reading. See “[Playing a Motion JPEG2000 Animation](#)” in the same chapter for details.

This method will throw an error if the compression fails. A CATCH statement can be used to trap these errors.

Syntax

```
Result = Obj->[IDLffMJPEG2000::]SetData (A1 ...An [, COMPONENT=value]
    [, FRAME_PERIOD=value] [, /ORDER] [, TILE_INDEX=value])
```

Return Value

Returns a byte value indicating success (1) or failure (0).

Arguments

A₁ ...A_n

One or more arrays of data representing the component(s) or tile(s) of data associated with the single frame being written (see “[Writing Frames, Components and Tiles](#)” on page 3476). The arrays may be 2- or 3-dimensional. A 2-dimensional array contains one frame component or tile component, and has the dimensions [*width*, *height*]. A 3-dimensional array has the dimensions [*nComponents*, *width*, *height*]. All arrays must have the same *width*, *height* dimensions.

The data type of the array arguments are converted based the `BIT_DEPTH` and `SIGNED` property values as follows:

<code>BIT_DEPTH</code>	Converted to Data Type
≤ 8	Byte
≥ 9 or ≤ 16	Integer, signed or unsigned based on <code>SIGNED</code> property
> 16	Long, signed or unsigned based on <code>SIGNED</code> property

Note

The data type of the input array has no effect on how the data is converted. If `BIT_DEPTH` and `SIGNED` are not set before the first call to `SetData`, data will be written as unsigned byte data. To write short or long integer data, or signed data, you must set the `BIT_DEPTH` and `SIGNED` properties before calling `SetData`.

Writing Frames, Components and Tiles

Frames may be written using multiple calls to `SetData` with each call transferring one or more components (channels or bands of data) or tile components. A tile component contains one frame component for a given tile and is the smallest unit of data that can be supplied to `SetData`.

The frame dimensions, tile dimensions and the number of components per frame are typically set prior to the first call to `SetData`. If they are not explicitly specified, they are inferred from the array parameters supplied in the first call to `SetData`. Once these properties (`DIMENSIONS`, `TILE_DIMENSIONS`, and `N_COMPONENTS`) are either explicitly set through `Init` or `SetProperty`, or set though the default action of `SetData`, they may not be changed. For example, if you pass in data arrays A_1 , A_2 , A_3 , A_4 and A_5 in a single call to `SetData`, this will be interpreted as a single frame with 5 components. All subsequent frames will be expected to have the same number of components.

The frame will advance when all data for the current frame has been passed in. For example, if you pass in one frame of data at a time, each `SetData` call advances the frame (the `N_FRAMES` property value increases by 1). If you pass in individual components or tiles, multiple `SetData` calls may be needed to advance the frame. Suppose your frame consists of 4 components, which you are passing in one at a time. You will need to call `SetData` four times before the frame will advance. If you have a frame that consists of 2 components and 4 tiles, and you are passing in a single tile component in each `SetData` call, the frame will only advance after 8 calls.

Note

If you are writing individual components, you must set the `N_COMPONENTS` property for the MJ2 file before the first call to `SetData`. If you are writing tiled data, you must set the `TILE_DIMENSIONS` and `DIMENSIONS` properties for the file before the first call to `SetData`.

If a file does not contain the expected number of tiles or components, an error will be generated when you call `IDLffJPEG2000::Commit` to store the data and close the file. If you do not complete writing all of the tiles or components, or if your array dimensions are not the same as the overall frame dimensions, the file storage process will not be completed. In such a case, reading the data back may result in unexpected or incorrect values.

Note

If transferring a frame with multiple calls to `SetData`, try to supply the data to `SetData` in a manner consistent with the progression setting of `PROGRESSION` property to ensure optimum performance and minimize memory requirements.

Color Space and Components

If not set prior to the first call to `SetData`, the `COLOR_SPACE` property will be automatically set based on the number of components passed in during the first call to `SetData` as follows:

Number of Components	Color Space
3	RGB
> 3 <	LUM

Note

If the `YCC` property is set (indicating that you want the library to convert from RGB to YCC before compressing the data), then you must supply all three frame components in the same call to `SetData` (either the entire frame or one tile at a time). If the components are provided in separate calls to `SetData`, the YCC conversion is not performed.

Keywords

COMPONENT

An integer value specifying the index of the component to be written in the current call to `SetData`. The default is 0. For example, suppose a frame consists of 4 components (`N_COMPONENTS` equals 4). If you pass in the first three components in one `SetData` call, you can pass in the fourth component in the next `SetData` call by setting `COMPONENT` equal to 3 (the zero-based index value of the fourth component). `COMPONENT` can only be used to write components sequentially.

You must set the `N_COMPONENTS` property before the first call to `SetData` if you are setting this keyword.

FRAME_PERIOD

A long value that indicates the duration of a frame in ticks. Each frame in an MJ2 file can be displayed a different period of time as defined by the `FRAME_PERIOD`. This value, in conjunction with the `TIMESCALE` property, determines the playback rate. See “[Computing Playback Rate](#)” on page 3444 for details.

The frame period of this frame and all subsequent frames will reflect the value set using the `FRAME_PERIOD` property, or set using this `FRAME_PERIOD` keyword.

ORDER

An integer value specifying the order in which to store data. Motion JPEG2000 frames are assumed to be stored in top-to-bottom order, while IDL usually assumes frames are in bottom-to-top order. By default (`ORDER=0`), this method will automatically flip the result to match Motion JPEG2000’s top-to-bottom order. Setting `ORDER` to a nonzero value will save the frame directly to the file without doing the vertical flip.

TILE_INDEX

An integer value that specifies the index of the tile to be written in the current `SetData` call. Frame tiles are numbered in raster scan fashion (from left to right starting at the upper left corner) beginning with an index value of 0. The default value for this keyword is 0. This keyword, like the `COMPONENT` keyword, lets you add data sequentially in separate `SetData` calls.

The tile indices must range from 0 to one less than the number of tiles in the frame, which is determined by the tile dimensions (`TILE_DIMENSIONS` property) and

frame dimensions ([DIMENSIONS](#) property). These properties must be set prior to the first call to `SetData` if you are setting this keyword.

Examples

Write frame components in separate `SetData` calls using the `COMPONENT` keyword. For a frame with 12 components, write the first five components in the first `SetData` call. Set `COMPONENT` to 5 (the zero-based index value of the sixth component) to add the remaining components in the next `SetData` call.

```
oMJ2write->SetProperty, N_COMPONENTS=12
result = oMJ2write->SetData(data0, data1, data2, data3, data4, $
    COMPONENT=0)
result = oMJ2write->SetData(data5, data6, data7, data8, data9, $
    data10, data11, COMPONENT=5)
```

Note

For additional examples using `SetData`, see [“Adding Data to MJ2 Animations”](#) (Chapter 6, *Using IDL*).

IDLffMJPEG2000:: SetProperty

The IDLffMJPEG::SetProperty procedure method sets the value of properties of an IDLffMJPEG2000 object. You can only set object properties for an associated file that is open for writing (`WRITE=1`).

Syntax

Obj->[IDLffMJPEG2000::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLffMJPEG2000 Properties](#)” on page 3438 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::StartSequentialReading

The IDLffMJPEG2000::StartSequentialReading function method initiates a sequential playback of a large number of frames. This method lets you configure what data is to be decompressed from each frame of the MJ2 file (the entire frame or a component, tile or region of the frame).

Internally, this method starts a background processing thread that decompresses frames into a frame buffer. This background thread allows the UI to remain active as described in [“About Processing Threads”](#) on page 3432).

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are used with a timer mechanism to create a sequential playback as described in [“Sequential Motion JPEG2000 Playback”](#) (Chapter 6, *Using IDL*).

Note

Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback methods as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if the decompression fails. A CATCH statement can be used to trap these errors.

Syntax

```
Result = Obj->[IDLffMJPEG2000::]StartSequentialReading
    ([, COMPONENT=value] [, DISCARD_LEVELS=value]
    [, MAX_LAYERS=value] [, N_COMPONENTS=value] [, /ORDER]
    [, REGION=vector] [, /RGB] [, START_FRAME_NUMBER=value]
    [, STOP_FRAME_NUMBER=value] [, TILE_INDEX=value] )
```

Return Value

Returns an integer value indicating success (1) or failure (0).

Arguments

None

Keywords

COMPONENT

An integer value indicating the zero-based index number of the first component to be returned as follows:

- This keyword is set and [N_COMPONENTS](#) is not set — returns all the components from the starting COMPONENT
- This keyword is set and [N_COMPONENTS](#) is set — returns the number of components specified by [N_COMPONENTS](#) from the starting component specified by COMPONENT

If this keyword is not set, all the components are returned. The default is 0.

DISCARD_LEVELS

An integer value specifying the number of resolution levels to be excluded from the result starting with the highest resolution level. For example, given a full-resolution frame that is 1024 by 1024 pixels:

Value	Description
0	The default. No data is discarded.
1	Discard 1 level, the highest resolution data (e.g. discard the 1024 by 1024 level, leaving the 512 by 512 data)
2	Discard 2 levels of data (e.g. discard the 1024 by 1024 and 512 by 512 levels, leaving the 256 by 256 data)

Determine the number of resolution levels by checking the [N_LEVELS](#) property.

MAX_LAYERS

An integer value specifying the maximum number of quality layers to be read. Each layer contains the information required to represent the image at a higher quality, given the information from all the previous layers. A value of 0, the default, means all available layers should be returned. If [MAX_LAYERS](#) is 3, data from the first, second and third quality layers will be combined in the returned data. Determine the number of quality layers in a file by checking the value of the [N_LAYERS](#) property.

N_COMPONENTS

An integer value specifying the number of components to return from the starting component specified by the [COMPONENT](#) keyword. If this keyword is set, but [COMPONENT](#) is not set, the default [COMPONENT](#) value (0) will be used.

ORDER

An integer value specifying the order in which to return data. Motion JPEG2000 frames are assumed to be stored in top-to-bottom order, while IDL usually assumes frames are in bottom-to-top order. By default ([ORDER](#)= 0), this method will automatically flip the result to match IDL's bottom-to-top order. Setting [ORDER](#) to a nonzero value will return the Motion JPEG2000 frames without doing the vertical flip.

REGION

A four-element long vector containing the rectangular region of the frame to read. The region is specified as [*startX*, *startY*, *width*, *height*], where *startX* and *startY* must be in the range 0 ... $2^{32}-2$, and *width* and *height* must be in the range 1 ... $2^{32}-1$. The region must contain at least some portion of the frame, or an error will occur. If the region is larger than the frame, or extends beyond the frame, only that portion that lies within the frame will be returned. This keyword, in combination with the [COMPONENT](#) keyword, lets you access any region from a particular component.

RGB

If set, the resulting data stream will be interpreted as RGB frames. The returned array will always have three components (red, green, and blue) with the dimensions [3, *width*, *height*]. See the following table for information on what data will be read if fewer than or more than 3 components are specified, or if the keyword is not set.

Note

The Motion JPEG2000 standard allows a decorrelating color transformation to be applied to the first three image components. This transformation is identical or similar to the conventional YCbCr color transformation. To determine if this transform has been applied, examine the [YCC](#) property.

RGB Set?	Number of Components	Outcome
Yes	More than 3	Only the first three components are returned.
	Less than 3	An error is thrown.
No	3	If a color transformation has been applied to the input stream, the three components which are encoded as YCC will automatically be converted to RGB. To avoid this conversion you must transfer more than or fewer than three components when using StartSequentialReading.
	Not equal to 3	Each component in the data stream will be placed in the result without interpretation. Result will have dimensions: [N_COMPONENTS, width, height].

You cannot specify RGB and `COMPONENT` or `N_COMPONENTS` at the same time. An error will be thrown in such cases.

START_FRAME_NUMBER

A long value specifying the frame index with which to start the sequential playback. If not set, the default value, 0, will be used.

STOP_FRAME_NUMBER

A long value specifying the frame index with which to stop the sequential playback. If not set, the stop frame will be the last frame in the file.

TILE_INDEX

An integer value specifying the index of the tile to return. Tiles are numbered in raster scan fashion (from left to right starting at the top-left corner) starting with an index value of 0. This keyword, in combination with the `COMPONENT` keyword, lets you access any tile from a particular component. When this keyword is set, the `REGION` keyword is ignored.

Examples

See the section of `IDLffMJPEG2000::GetSequentialData` for a simple example that uses the four sequential playback methods.

Version History

6.3	Introduced
-----	------------

IDLffMJPEG2000::StopSequentialReading

The IDLffMJPEG2000::StopSequentialReading function method releases the frame buffer memory and shuts down the background processing thread, if it is still running. Call this method when a sequential playback has been completed. Until StopSequentialReading is called, the decompressed frames will remain in the frame buffer.

The StartSequentialReading, GetSequentialData, ReleaseSequentialData and StopSequentialReading methods are used with a timer mechanism to create a sequential playback as described in “[Sequential Motion JPEG2000 Playback](#)” (Chapter 6, *Using IDL*).

Note

Always use a widget timer or IDLitWindow timer mechanism to control the playback rate. Avoid using the WAIT procedure with sequential playback as the interaction between the procedure and the background processing thread will cause adverse side effects on UNIX platforms.

This method will throw an error if the decompression fails. A CATCH statement can be used to trap these errors.

Syntax

```
Result = Obj->[IDLffMJPEG2000::]StopSequentialReading( )
```

Return Value

Returns an integer indicating success (1) or failure (0).

Arguments

None

Keywords

None

Examples

See the section of IDLffMJPEG2000::GetSequentialData for a simple example that uses the four sequential playback methods.

Version History

6.3	Introduced
-----	------------

IDLffMrSID

An IDLffMrSID object class is used to query information about and load image data from a MrSID (.sid) image file.

Note

The IDLffMrSID object is available only under Microsoft Windows. See [“Feature Support by Operating System”](#) (*What’s New in IDL 7.1*) for details.

Superclasses

None

Creation

See [IDLffMrSID::Init](#)

Properties

Objects of this class have the following properties. See [“IDLffMrSID Properties”](#) on page 3489 for details on individual properties.

- [QUIET](#)

Methods

This class has the following methods:

- [IDLffMrSID::Cleanup](#)
- [IDLffMrSID::GetDimsAtLevel](#)
- [IDLffMrSID::GetImageData](#)
- [IDLffMrSID::GetProperty](#)
- [IDLffMrSID::Init](#)

Version History

5.5	Introduced
-----	------------

IDLffMrSID Properties

IDLffMrSID objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffMrSID::Init](#).

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties.

- [QUIET](#)

QUIET

A Boolean value to indicate whether error messages are suppressed while constructing the IDLffMrSID object. If this value is true, the errors messages are suppressed. Otherwise, the messages are printed to the Output Log.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLffMrSID::Cleanup

The IDLffMrSID::Cleanup procedure method deletes all MrSID objects, closing the MrSID file in the process. It also deletes the IDL objects used to communicate with the MrSID library.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffMrSID::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.5	Introduced
-----	------------

IDLffMrSID::GetDimsAtLevel

The IDLffMrSID::GetDimsAtLevel function method is used to retrieve the dimensions of the image at a given level. This can be used, for example, to determine what level is required to fit the image into a certain area.

Syntax

Result = *Obj*->[IDLffMrSID::]GetDimsAtLevel (*Level*)

Return Value

Returns a floating-point two-element vector containing the dimensions of the image at a given level.

Arguments

Level

A scalar integer specifying the level at which the dimensions are to be determined. This level must be in the range returned by the LEVELS keyword of IDLffMrSID::GetProperty.

Keywords

None

Examples

Initialize the MrSID file object.

```
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $  
    SUBDIRECTORY = ['examples', 'data']))
```

Get the range of levels of resolution contained within the file.

```
oFile->GetProperty, LEVELS = lvls  
PRINT, lvls
```

IDL prints,

```
-9    4
```

Print the image dimensions at the lowest image resolution where image level = 4.

```
imgLevelA = MAX(lvls)
dimsAtA = oFile->GetDimsAtLevel(imgLevelA)
PRINT, 'Dimensions of lowest resolution image is', dimsAtA
```

IDL prints,

```
32  32
```

Print the image dimensions at full resolution where image level = 0

```
dimsAtFull = oFile->GetDimsAtLevel(0)
PRINT, 'Dimensions of full resolution image is', dimsAtFull
```

IDL prints,

```
512  512
```

Print the image dimensions at the highest resolution where image level = -9

```
highestLvl = MIN(lvls)
dimsAtHighest = oFile->GetDimsAtLevel(highestLvl)
PRINT, 'Dimensions of highest resolution image is', dimsAtHighest
```

IDL prints,

```
262144  262144
```

Clean up object references.

```
OBJ_DESTROY, [oFile]
```

Version History

5.5	Introduced
-----	------------

IDLffMrSID::GetImageData

The IDLffMrSID::GetImageData function method extracts and returns the image data from the MrSID file at the specified level and location.

Syntax

```
Result = Obj->[IDLffMrSID::]GetImageData ([, LEVEL = lvl]  
[, SUB_RECT = rect])
```

Return Value

Returns an n -by- w -by- h array containing the image data where n is 1 for grayscale or 3 for RGB images, w is the width and h is the height.

Note

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left corner of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left corner of the image.

Arguments

None

Keywords

LEVEL

Set this keyword to an integer that specifies the level at which to read the image.

If this keyword is not set, the maximum level is used which returns the minimum resolution (see the LEVELS keyword to IDLffMrSID::GetProperty).

SUB_RECT

Set this keyword to a four-element vector $[x, y, xdim, ydim]$ specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying portions of a high-resolution image.

If this keyword is not set, the whole image will be returned. This may require significant memory if a high-resolution image level is selected.

If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

Note

The elements of SUB_RECT are measured in pixels at the current level. This means the point $x = 10$, $y = 10$ at level 1 will be located at $x = 20$, $y = 20$ at level 0 and $x = 5$, $y = 5$ at level 2.

Examples

```

PRO MrSID_GetImageData

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile->GetProperty, LEVELS = lvlS
PRINT, lvlS
; IDL prints, -9, 4

; Get the image data at level 0.
imgDataA = oFile->GetImageData(LEVEL = 0)
HELP, 'image array data at full resolution', imgDataA
; IDL prints, Array[1, 512, 512] indicating a grayscale 512 x 512
array.

; Display the full resolution image.
oImgA = OBJ_NEW('IDLgrImage', imgDataA)
oModelA = OBJ_NEW('IDLgrModel')
oModelA->Add, oImgA
XOBJVIEW, oModelA, BACKGROUND = [0,0,0], $
    TITLE = 'Full Resolution Image', /BLOCK

; Get the image data of a higher resolution image,
imgDataB = oFile->GetImageData(LEVEL = -2)
HELP, imgDataB
; IDL returns [1,2048,2048] indicating a grayscale 2048 x 2048
array.

```

```
; To save processing time, display only a 1024 x 1024 portion of
; the high resolution, using 512,512 as the origin.
imgDataSelect = oFile->GetImageData(LEVEL = -2,$
    SUB_RECT = [512, 512, 1024, 1024])
oImgSelect = OBJ_NEW('IDLgrImage', imgDataSelect)
oModel = OBJ_NEW('IDLgrModel')
oModel->Add, oImgSelect

XOBJVIEW, oModel, BACKGROUND = [0,0,0], $
    TITLE = 'Detail of High Resolution Image', /BLOCK

; Clean up object references.
OBJ_DESTROY, [oFile, oImgA, oModelA, oImgSelect, oModel]

END
```

Version History

5.5	Introduced
-----	------------

IDLffMrSID::GetProperty

The IDLffMrSID::GetProperty function method is used to query properties associated with the MrSID image.

Syntax

```
Obj->[IDLffMrSID::]GetProperty [, CHANNELS=nChannels]
    [, DIMENSIONS=Dims] [, LEVELS=Levels] [, PIXEL_TYPE=pixelType]
    [, TYPE=strType] [, GEO_VALID=geoValid] [, GEO_PROJTYPE=geoProjType]
    [, GEO_ORIGIN=geoOrigin] [, GEO_RESOLUTION=geoRes]
```

Arguments

None

Keywords

CHANNELS

Set this keyword to a named variable that will contain the number of image bands. For RGB images this is 3, for grayscale it is 1.

DIMENSIONS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*width, height*] that specifies the dimensions of the MrSID image at level 0 (full resolution).

GEO_ORIGIN

Set this keyword to a named variable that will contain a two-element double precision array of the form [*x, y*] that specifies the location of the center of the upper-left pixel.

GEO_PROJTYPE

Set this keyword to a named variable that will contain an unsigned integer that specifies the geoTIFF projected coordinate system type code. For example, type code 32613 corresponds to PCS_WGS84_UTM_zone_13N.

For more information on the geoTIFF file type and available type codes see:

<http://www.remotesensing.org/geotiff/geotiff.html>

GEO_RESOLUTION

Set this keyword to a named variable that will contain a two-element double precision array of the form [*xres*, *yres*] that specifies the pixel resolution.

GEO_VALID

Set this keyword to a named variable that will contain a long integer that is set to:

- 1 - If the MrSID image contains valid georeferencing data.
- 0 - If the MrSID image does not contain georeferencing data or the data is in an unsupported format.

Note

Always verify that this keyword returns 1 before using the data returned by any other GEO_* keyword.

LEVELS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*minlvl*, *maxlvl*] that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

PIXEL_TYPE

Set this keyword to a named variable that will contain the IDL basic type code for a pixel sample. For a list of the data types indicated by each type code, see the “IDL Type Codes” section of the [SIZE](#) function.

TYPE

Set this keyword to a named variable that will contain a string identifying the file format. This should always be MrSID.

Examples

```
PRO MrSID_GetProperty

; Initialize the MrSID object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
    SUBDIRECTORY = ['examples', 'data']))
```

```

; Get the property information of the MrSID file.
oFile->GetProperty, CHANNELS = chan, LEVELS = $
    lvls, Pixel_Type = pType, TYPE = fileType, GEO_VALID = geoQuery

; Print MrSID file information.
PRINT, 'Number of image channels = ', chan
; IDL returns 1 indicating one image band.

PRINT, 'Range of image levels = ', lvls
; IDL returns -9, 4, the minimum and maximum level values.

PRINT, 'Type code of image pixels = ', pType
; IDL returns 1 indicating byte data type.

PRINT, 'Image file type = ', FileType
; IDL returns "MrSID"

PRINT, 'Result of georeferencing data query = ', geoQuery
; IDL returns 0 indicating that the image does not contain
; georeferencing data.

; Destroy object references.
OBJ_DESTROY, [oFile]

END

```

Version History

5.5	Introduced
-----	------------

IDLffMrSID::Init

The IDLffMrSID::Init function method initializes an IDLffMrSID object containing the image data from a MrSID image file.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = OBJ_NEW('IDLffMrSID', *Filename* [, *PROPERTY=value*])

or

Result = *Obj*->[IDLffMrSID::]Init(*Filename* [, *PROPERTY=value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string argument containing the full path and filename of a MrSID file to be accessed through this IDLffMrSID object.

Note

This is a required argument; it is not possible to create an IDLffMrSID object without specifying a valid MrSID file.

Keywords

Any property listed under “[IDLffMrSID Properties](#)” on page 3489 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

```
oMrSID = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $  
    SUBDIRECTORY = ['examples', 'data']))
```

- [IDLffShape::Open](#)
- [IDLffShape::PutEntity](#)
- [IDLffShape::SetAttributes](#)

Version History

5.4	Introduced
5.6	Added N_RECORDS, DBF_ONLY properties

Overview of ESRI Shapefiles

An ESRI Shapefile stores nontopological geometry and attribute information for the spatial features in a data set.

A Shapefile consists of a main file (.shp), an index file (.shx), and a dBASE table (.dbf). For example, the Shapefile “states” would have the following files:

- states.shp
- states.shx
- states.dbf

Naming Conventions for a Shapefile

All the files that comprise an ESRI Shapefile must adhere to the 8.3 filename convention and must be lower case. The main file, index file, and dBASE file must all have the same prefix. The prefix must start with an alphanumeric character and can contain any alphanumeric, underscore (_), or hyphen (-). The main file suffix must use the .shp extension, the index file the .shx extension, and the dBASE table the .dbf extension.

Major Elements of a Shapefile

A Shapefile consists of the following elements that you can access through the `IDLffShape` class:

- Entities
- Attributes

Entities

The geometry for a feature is stored as a shape comprising a set of vector coordinates (referred to as ‘entities’). The (non-null) entities in a Shapefile must all be of the same type. The following are the possible types for entities in a Shapefile:

Shape Type	Type Code
Point	1
PolyLine	3
Polygon	5

Table 30-16: Entity Types

Shape Type	Type Code
MultiPoint	8
PointZ	11
PolyLineZ	13
PolygonZ	15
MultiPointZ	18
PointM	21
PolyLineM	23
PolygonM	25
MultiPointM	28
MultiPatch	31

Table 30-16: Entity Types (Continued)

When retrieving entities using the `IDLffShape::GetEntity` method, an IDL structure is returned. This structure has the following fields:

Field	Data Type	Description
SHAPE_TYPE	Long integer	The entity type.
ISHAPE	Long integer	A read-only field containing the index of the specific entity within the shape object. This value is set automatically when the shape file is written.

Table 30-17: Entity Structure Field Data Types

Field	Data Type	Description
BOUNDS	Eight-element, double-precision array	<p>A bounding box that specifies the range limits of the entity. This eight element array contains the following information:</p> <ul style="list-style-type: none"> • Index 0 — X minimum value • Index 1 — Y minimum value • Index 2 — Z minimum value (if Z is supported by type) • Index 3 — Measure minimum value (if measure is supported by entity type) • Index4 — X maximum value • Index5 — Y maximum value • Index6 — Z maximum value (if Z is supported by the entity type) • Index7 — Measure maximum value (if measure is supported by entity type) <p>Note - If the entity is a point type, the values contained in the bounds array are also the values of the entity.</p>
N_VERTICES	Long integer	<p>The number of vertices in the entity. If this value is one and the entity is a POINT type (POINT, POINTM, POINTZ), the vertices pointer will be set to NULL and the entity value will be maintained in the BOUNDS field.</p>

Table 30-17: Entity Structure Field Data Types (Continued)

Field	Data Type	Description
VERTICES	Pointer to Vertices array	<p>An IDL pointer that contains the vertices of the entity. This pointer contains a double array that has one of the following formats:</p> <ul style="list-style-type: none"> • [2, <i>N</i>] - If Z data is not present • [3, <i>N</i>] - If Z data is present <p>where <i>N</i> is the number of vertices. These array formats can be passed to the polygon and polyline objects of IDL Object Graphics.</p> <p>Note - This pointer will be null if the entity is a point type, with the values maintained in the BOUNDS array.</p>
MEASURE	Pointer to Measure array	<p>If the entity has a measure value (this is dependent on the entity type), this IDL pointer will contain a vector array of measure values. The length of this vector is N_VERTICES.</p> <p>Note - This pointer will be null if the entity is of type POINTM, with the values contained in the BOUNDS array.</p>
N_PARTS	Long integer	<p>If the values of the entity are separated into parts, the break points are enumerated in the parts array. This field lists the number of parts in this entity. If this value is 0, the entity is one part and the PARTS pointer will be NULL.</p>

Table 30-17: Entity Structure Field Data Types (Continued)

Field	Data Type	Description
PARTS	Pointer to Parts array	An IDL pointer that contains an array of indices into the vertex/measure arrays. These values represent the start of each part of the entity. The index range of each entity part is defined by the following: <ul style="list-style-type: none"> • Start = Parts[I] • End = Parts[I+1]-1 or the end of the array
PART_TYPES	Pointer to part types	This IDL pointer is only valid for entities of type MultiPatch and defines the type of the particular part. If the entity type is not MultiPatch, part types are assumed to be type RING (SHPP_RING). Note - This pointer is NULL if the entity is not type MultiPatch.
ATTRIBUTES	Pointer to Attribute array	If the attributes for an entity were requested, this field contains an IDL pointer that contains a structure of attributes for the entity. For more information on this structure, see “ Attributes ” on page 3507.

Table 30-17: Entity Structure Field Data Types (Continued)

Attributes

A Shapefile provides the ability to associate information describing each entity (a geometric element) contained in the file. This descriptive information, called attributes, consists of a set of named data elements for each geometric entity contained in the file. The set of available attributes is the same for every entity contained in a Shapefile, with each entity having its own set of attribute values.

An attribute consist of two components:

- A name
- A data value

The name consists of an 11 character string that is used to identify the data value. The data value is not limited to any specific format.

The two components that form an attribute are accessed differently using the shape object. To get the name of attributes for the specific file, the `ATTRIBUTE_NAMES` keyword to the `IDLffShape::GetProperty` method is used. This returns a string array that contains the names for the attributes defined for the file.

To get the attribute values for an entity, the `IDLffShape::GetAttributes` method is called or the `ATTRIBUTES` keyword of the `IDLffShape::GetEntity` method is set. In each case, the attribute values for the specified entity is returned as an anonymous IDL structure. The numeric order of the fields in the returned structure map to the numeric order of the attributes defined for the file. The actual format of the returned structure is:

```
ATTRIBUTE_0 : VALUE,
ATTRIBUTE_1 : VALUE,
ATTRIBUTE_2 : VALUE,
...
ATTRIBUTE_<N-1> : VALUE
```

To access the values in the returned structure, you can either hard code the structure field names or use the structure indexing feature of IDL.

Accessing Shapefiles

The following example shows how to access data in a Shapefile. This example sets up a map to display parts of a Shapefile, opens a Shapefile, reads the entities from the Shapefile, and then plots only the state of Colorado:

```
PRO ex_shapefile

DEVICE, RETAIN=2, DECOMPOSED=0

!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0           ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255    ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0       ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0     ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255
```

```

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,45, -120, /ISOTROPIC, $
/HORIZON, E_HORIZON={FILL:1, COLOR:blue}, $
/GRID, COLOR=black, /NOBORDER

; Fill the continent boundaries:
MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=green

; Overplot coastline data:
MAP_CONTINENTS, /COASTS, COLOR=black

; Show national borders:
MAP_CONTINENTS, /COUNTRIES, COLOR=black

; Open the states Shapefile in the examples directory
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

; Parsing through the entities and only plotting the state of
; Colorado
FOR x=1, (num_ent-1) DO BEGIN
; Get the Attributes for entity x
attr = myshape->IDLffShape::GetAttributes(x)
; See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
; entity x
IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN
; Get entity
ent=myshape->IDLffShape::GetEntity(x)
; Plot entity
POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*], $
COLOR=yellow
; Clean-up of pointers
myshape->IDLffShape::DestroyEntity, ent
ENDIF
ENDFOR

; Close the Shapefile
OBJ_DESTROY, myshape

END

```

This results in the following:

Figure 30-2: Example Use of Shapefiles

Creating New Shapefiles

To create a Shapefile, you need to create a new Shapefile object, define the entity and attributes definitions, and then add your data to the file. For example, the following program creates a new Shapefile (`cities.shp`), defines the entity type to be “Point”, defines 2 attributes (`CITY_NAME` and `STATE_NAME`), and then adds an entity to the new file:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
  SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->AddAttribute, 'CITY_NAME', 7, 25, $
  PRECISION=0
mynewshape->AddAttribute, 'STAT_NAME', 7, 25, $
  PRECISION=0
```

```

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000
entNew.N_VERTICES = 1 ; take out of example, need as workaround

;Create structure for new attributes
attrNew = mynewshape ->GetAttributes(/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape -> PutEntity, entNew

;Note that because this is a new shapefile, the index of
;the new entity is zero.
entity_index=0

;Add the Colorado attributes to new shapefile.
mynewshape -> SetAttributes, entity_index, attrNew

;Close the shapefile
OBJ_DESTROY, mynewshape

END

```

Updating Existing Shapefiles

You can modify existing Shapefiles with the following:

- Adding new entities
- Adding new attributes (only to Shapefiles without any existing values in any attributes)
- Modifying existing attributes

Note

You cannot modify existing entities.

For example, the following program adds an entity and attributes for the city of Boulder to the `cities.shp` file created in the previous example:

```

PRO ex_shapefile_modify

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
    SUBDIR=['examples', 'data']), /UPDATE)

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 200
entNew.BOUNDS[0] = -105.25100
entNew.BOUNDS[1] = 40.026878
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -105.25100
entNew.BOUNDS[5] = 40.026878
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000
entNew.N_VERTICES = 1 ; take out of example, need as workaround

;Create structure for new attributes
attrNew = myshape ->GetAttributes(/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Boulder'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
myshape -> PutEntity, entNew

;Determine the zero-based index of the new entity
myshape -> GetProperty, N_ENTITIES=num_entities
entity_index=num_entities-1

;Add the Colorado attributes to new shapefile
myshape -> SetAttributes, entity_index, attrNew

;Close the shapefile
OBJ_DESTROY, myshape

```

END

Graphing an Updated Shapefile

The following program graphs the `cities.shp` file that was created and updated in the previous examples:

```

pro plot_cities

DEVICE, RETAIN=2, DECOMPOSED=0

!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0           ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255    ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0       ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0     ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,39, -104, SCALE=9e6, /ISOTROPIC, $
        /HORIZON, E_HORIZON={FILL:1, COLOR:green}, $
        COLOR=yellow

; Show state borders:
MAP_CONTINENTS, /USA, COLOR=black

;Open the states Shapefile in the examples directory
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
        SUBDIR=['examples', 'data']))

;Get the number of entities so we can parse through them
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

;Parsing through the entities and only plotting the state of
;Colorado
FOR x=1, (num_ent-1) DO BEGIN
    ;Get the Attributes for entity x
    attr = myshape->IDLffShape::GetAttributes(x)
    ;See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
    ;entity x
    IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN

```

```

        ;Get entity
        ent=myshape->IDLffShape::GetEntity(x)
        ;Plot entity
        POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*], $
            COLOR=yellow
        ;Clean-up of pointers
        myshape->IDLffShape::DestroyEntity, ent
    ENDFIF

ENDFOR

;Close the states Shapefile
OBJ_DESTROY, myshape

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
    SUBDIR=['examples', 'data']))

;Get the number of entities so we can parse through them
myshape->IDLffShape::GetProperty, N_ENTITIES=num_ent

;Plot the cities on the map of Colorado

FOR x=0, (num_ent-1) DO BEGIN
    ;Get entity
    ent=myshape->IDLffShape::GetEntity(x)

    ;Get city attribute
    attr = myshape ->IDLffShape::GetAttributes(x)

    ;Plot the cities with a symbol, as well as the city name
    plots, ent.BOUNDS[0], ent.BOUNDS[1], psym=5, color=black
    xyouts, ent.BOUNDS[0] + 0.3, ent.BOUNDS[1], $
        attr.ATTRIBUTE_0, color=black

    ;Clean-up of pointers
    myshape->IDLffShape::DestroyEntity, ent

ENDFOR

;Close the Shapefile
OBJ_DESTROY, myshape

END

```

IDLffShape Properties

IDLffShape objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffShape::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffShape::Init](#).

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties.

- [ATTRIBUTE_INFO](#)
- [ATTRIBUTE_NAMES](#)
- [DBF_ONLY](#)
- [ENTITY_TYPE](#)
- [FILENAME](#)
- [IS_OPEN](#)
- [N_ATTRIBUTES](#)
- [N_ENTITIES](#)
- [N_RECORDS](#)
- [UPDATE](#)

ATTRIBUTE_INFO

A array of structures containing the attribute information for each attribute. The attribute information structures have the following fields:

Field	Description
NAME	A string that contains the name of the attribute
TYPE	The IDL type code of the attribute

Table 30-18: Attribute Information Fields

Field	Description
WIDTH	The width of the attribute
PRECISION	The precision of the attribute

Table 30-18: Attribute Information Fields (Continued)

The file must be open to obtain this information.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ATTRIBUTE_NAMES

A string array containing the names of each attribute in the Shapefile object.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DBF_ONLY

A non-zero, positive integer value indicating whether the underlying dBASE table (.dbf) component of the shapefile is opened while all other entity related files are left closed. The following two values are accepted for this property:

- 1 - Open an existing .dbf file,
- Greater than 1 - Create a new .dbf file

Note

The UPDATE keyword is required to open the .dbf file for updating.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

ENTITY_TYPE

If retrieving this property, its value is an integer representing the type code for the entities contained in the Shapefile object. If the value is unknown, this method returns -1. For more information on entity type codes, see “Entities” on page 3503.

If setting this property, its value is an integer representing the entity type of a new Shapefile. Use this setting only when creating a new Shapefile. For more information on entity types, see “Entities” on page 3503.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

FILENAME

A string representing the fully qualified path name of the Shapefile in the current Shapefile object.

Note

FILENAME can only be set via an argument to the `IDLffShape::Init` method.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IS_OPEN

An integer value representing information about the status of a Shapefile. The following values can be returned:

0	File is not open
1	File is open in read-only mode
3	File is open in update mode

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_ATTRIBUTES

A longword integer representing the number of attributes associated with a Shapefile object. If the number of attributes is unknown, this property returns 0.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_ENTITIES

A longword integer representing the number of entities contained in Shapefile object. If the number of entities is unknown, this property returns 0.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_RECORDS

A longword integer representing the number of records in the dBASE table (.dbf) component of the Shapefile. In a normal operating mode, this process is accomplished by getting the number of entities. However, in DBF_ONLY mode, no entity file exists.

Property Type	Long		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UPDATE

A Boolean value indicating whether the file opened for writing. The file is opened for writing if this property is set to true. The default is read-only.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLffShape::AddAttribute

The IDLffShape::AddAttribute method adds an attribute definition to a Shapefile. Adding the attribute definition is required before adding the actual attribute data to a file. For more information on attributes, see [“Attributes”](#) on page 3507.

Note

You can only define new attributes to Shapefiles that do not have any existing values in any attributes.

Syntax

Obj->[IDLffShape::]AddAttribute, *Name*, *Type*, *Width* [, PRECISION=*integer*]

Arguments

Name

Set to a string that contains the attribute name. Name values are limited to 11 characters. Arguments longer than 11 characters will be truncated.

Type

Set to the IDL type code that corresponds to the data type that will be stored in the attribute. The valid types are:

3	Longword integer
5	Double-precision floating-point
7	String

Width

Set to the user-defined width of the field for the data value of the attribute. The following table describes the possible values depending on the defined *Type*:

Longword Integer	Establishes the number of digits of the largest number that can be represented
Double-precision floating-point	Establishes the total number of digits, including the decimal point and the number of positions after the decimal point (see the PRECISION keyword)
String	Establishes the maximum length of the string that can be stored

Keywords

PRECISION

Set this keyword to the number of positions to be included after the decimal point. The default is 8. This keyword is only valid for fields defined as double-precision floating-point.

Examples

For an example of AddAttribute, see [“Creating New Shapefiles”](#) on page 3510.

Note

If `cities.shp` already contains data in an attribute for any of the entities defined in the file, this operation will fail.

Version History

5.4	Introduced
-----	------------

IDLffShape::Cleanup

The IDLffShape::Cleanup procedure method performs all cleanup on a Shapefile object. If the Shapefile being accessed by the object is open and the file has been modified, the new information is written to the file if one of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

Note

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffShape::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.4	Introduced
-----	------------

IDLffShape::Close

The IDLffShape::Close procedure method closes a Shapefile. If the file has been modified, it is also written to the disk if neither of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

If the file has been modified and one of the previous conditions is not met, the file is closed and the changes are not written to disk.

Syntax

Obj->[\[IDLffShape::\]Close](#)

Arguments

None

Keywords

None

Version History

5.4	Introduced
-----	------------

IDLffShape::DestroyEntity

The IDLffShape::DestroyEntity procedure method frees memory associated with the entity structure. For more information on the entity structure, see “Entities” on page 3503.

Syntax

Obj->[IDLffShape::]DestroyEntity, *Entity*

Arguments

Entity

A scalar or array of entities to be destroyed.

Keywords

None

Examples

In the following example, all of the entities from the `states.shp` Shapefile are read and then the DestroyEntity method is called to clean up all pointers:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
    ;Read the entity x
    ent = myshape->GetEntity(x)
    ;Clean-up of pointers
    myshape->DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape
END
```

Version History

5.4	Introduced
-----	------------

IDLffShape::GetAttributes

The IDLffShape::GetAttributes function method retrieves the attributes for the entities you specify from a Shapefile.

Syntax

```
Result = Obj->[IDLffShape::]GetAttributes([Index] [, /ALL]  
[, /ATTRIBUTE_STRUCTURE] )
```

Return Value

Returns an anonymous structure array. For more information on the structure, see “Attributes” on page 3507.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve the attributes, with 0 being the first entity in the Shapefile.

Note

If you do not specify *Index* and the ALL keyword is not set, the attributes for the first entity (0) are returned.

Keywords

ALL

Set this keyword to retrieve the attributes for all entities in a Shapefile. If you set this keyword, the *Index* argument is not required.

ATTRIBUTE_STRUCTURE

Set this keyword to return an empty attribute structure that can then be used with the [IDLffShape::SetAttributes](#) method to add attributes to a Shapefile.

Examples

In the first example, we retrieve the attributes associated with entity at location 0 (the first entity in the file):

```
attr = myShape->getAttributes( 0)
```

In the next example, we retrieve the attributes associated with entities 10 through 20:

```
attr = myShape->getAttributes( 10+indgen(11) )
```

In the next example, we retrieve the attributes for entities 1,4, 9 and 70:

```
attr = myShape->getAttributes( [1, 4, 9, 70] )
```

In the next example, we retrieve all the attributes for a Shapefile:

```
attr = myShape->getAttributes( /ALL )
```

Version History

5.4	Introduced
-----	------------

IDLffShape::GetEntity

The IDLffShape::GetEntity function method returns the entities you specify from a Shapefile.

Syntax

Result = *Obj*->[IDLffShape::]GetEntity([*Index*] [, /ALL] [, /ATTRIBUTES])

Return Value

Returns a type {IDL_SHAPE_ENTITY} structure array. For more information on the structure, see “Entities” on page 3503.

Note

Since an entity structure contains IDL pointers, you must free all the pointers returned in these structures when the entity is no longer needed using the [IDLffShape::DestroyEntity](#) method.

Note

Since entities cannot be modified in a Shapefile, an entity is read directly from the Shapefile each time you use the IDLffShape::GetEntity method even if you have already read that entity. If you modify the structure array returned by this method for a given entity and then use IDLffShape::GetEntity on that same entity, the modified data will NOT be returned, the data that is actually written in the file is returned.

Arguments

Index

A scalar or array of longs specifying the entities for which you want to retrieve with 0 being the first entity in the Shapefile. If the ALL keyword is set, this argument is not required. If you do not specify any entities and the ALL keyword is not set, the first entity (0) is returned.

Keywords

ALL

Set this keyword to retrieve all entities from the Shapefile. If this keyword is set, the Index argument is not required.

ATTRIBUTES

Set this keyword to return the attributes in the entity structure. If not set, the ATTRIBUTES tag in the entity structure will be a null IDL pointer.

Examples

In the following example, all of the entities from the `states.shp` Shapefile are read:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape->GetProperty, N_ENTITIES=num_ent

; Read all the entities. The entity array in a Shapefile
; starts with index zero (0).
FOR x=0, (num_ent-1) DO BEGIN
    ;Read the entity x
    ent = myshape->GetEntity(x)
    ;Clean-up of pointers
    myshape->DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

Version History

5.4	Introduced
-----	------------

IDLffShape::GetProperty

The IDLffShape::GetProperty procedure method returns the values of properties associated with a Shapefile object. These properties are:

- Number of entities
- The type of the entities
- The number of attributes associated with each entity
- The names of the attributes
- The name, type, width, and precision of the attributes
- The status of a Shapefile
- The filename of the Shapefile object

Syntax

Obj->[IDLffShape::]GetProperty [, *PROPERTY*=*variable*]

Arguments

None

Keywords

Any property listed under “IDLffShape Properties” on page 3515 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Examples

In the following example, the number of entities and the entity type is returned:

```
PRO entity_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
  SUBDIR=['examples', 'data']))

; Get the number of entities and the entity type.
myshape->GetProperty, N_ENTITIES=num_ent, $
  ENTITY_TYPE=ent_type
```

```

; Print the number of entities and the type.
PRINT, 'Number of Entities: ', num_ent
PRINT, 'Entity Type: ', ent_type

; Close the Shapefile.
OBJ_DESTROY, myshape

END

```

This results in the following:

```

Number of Entities:      51
Entity Type:            5

```

In the next example, the definitions for attribute 1 are returned:

```

PRO attribute_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))

; Get the info for all attribute.
myshape->GetProperty, ATTRIBUTE_INFO=attr_info

; Print Attribute Info.
PRINT, 'Attribute Number: ', '1'
PRINT, 'Attribute Name: ', attr_info[1].name
PRINT, 'Attribute Type: ', attr_info[1].type
PRINT, 'Attribute Width: ', attr_info[1].width
PRINT, 'Attribute Precision: ', attr_info[1].precision

; Close the Shapefile.
OBJ_DESTROY, myshape

END

```

This results in the following:

```

Attribute Number:      1
Attribute Name:       STATE_NAME
Attribute Type:        7
Attribute Width:      25
Attribute Precision:   0

```

Version History

5.4	Introduced
-----	------------

IDLffShape::Init

The IDLffShape::Init function method initializes or constructs a Shapefile object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Result = OBJ_NEW('IDLffShape' [, Filename] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLffShape::]Init([, Filename] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. If this file exists, it is opened. If the file does not exist, a new Shapefile object is constructed. You do not need to use [IDLffShape::Open](#) to open an existing file when specifying this argument.

Note

The .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

Note

The value specified by the *Filename* argument is used to initialize the value of the **FILENAME** property of the IDLffShape object.

Keywords

Any property listed under “[IDLffShape Properties](#)” on page 3515 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Examples

In the following example, we create a new Shapefile object and open the `examples/data/states.shp` file:

```
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']))
```

Version History

5.4	Introduced
-----	------------

IDLffShape::Open

The IDLffShape::Open function method opens a specified Shapefile.

Syntax

```
Result = Obj->[IDLffShape::]Open( 'Filename' [, /DBF_ONLY]  
    [, ENTITY_TYPE='value'] [, /UPDATE] )
```

Return Value

Returns 1 if the file can be read successfully. If not able to open the file, it returns 0.

Arguments

Filename

A scalar string containing the full path and filename of a Shapefile (.shp) to open. Note that the .shp, .shx, and .dbx files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

Keywords

DBF_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (.dbf) component of the shapefile is opened. All entity related files are left closed. Two values to this keyword are accepted: 1 - Open an existing .dbf file, > 1 - Create a new .dbf file

The UPDATE keyword is required to open the .dbf file for updating.

ENTITY_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when creating a new Shapefile. For more information on entity types, see “Entities” on page 3503.

UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

Examples

In the following example, the file `examples/data/states.shp` is opened for reading and writing:

```
status = myShape->Open(FILEPATH('states.shp', $
    SUBDIR=['examples', 'data']), /UPDATE)
```

Version History

5.4	Introduced
-----	------------

IDLffShape::PutEntity

The IDLffShape::PutEntity procedure method inserts an entity into the Shapefile object. The entity must be in the proper structure. For more information on the structure, see “Entities” on page 3503.

Note

The shape type of the new entity must be the same as the shape type defined for the Shapefile. If the shape type has not been defined for the Shapefile using the ENTITY_TYPE keyword for the IDLffShape::Open or IDLffShape::Init methods, the first entity that is inserted into the Shapefile defines the type.

Note

Only new entities can be inserted into a Shapefile. Existing entities cannot be updated.

Syntax

Obj->[IDLffShape::]PutEntity, *Data*

Arguments

Data

A scalar or an array of entity structures.

Keywords

None

Examples

In the following example, we create a new shapefile, define a new entity, and then use the PutEntity method to insert it into the new file:

```
PRO ex_shapefile_putentity

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape',
DIALOG_PICKFILE(FILE='shape_entity.shp', /WRITE), $
/UPDATE, ENTITY_TYPE=1)
```

```
; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity.
entNew.SHAPE_TYPE = 1
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Add the new entity to new shapefile.
mynewshape->PutEntity, entNew

; Close the shapefile
mynewshape->Close

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

Version History

5.4	Introduced
-----	------------

IDLffShape::SetAttributes

The `IDLffShape::SetAttributes` procedure method sets the attributes for a specified entity in a Shapefile object.

Syntax

Obj->[[IDLffShape::](#)]SetAttributes, *Index*, *Attribute_Num*, *Value*

or

Obj->[[IDLffShape::](#)]SetAttributes, *Index*, *Value*

Arguments

Attribute_Num

The field number in the attribute structure for the attribute whose value is being set. This value is 0-based.

Attributes

An Attribute structure whose fields match the fields in the attribute table. If *Attributes* is an array, the entities specified in *Index*, up to the size of the Attributes array, are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

The type of this Attribute structure must match the type that is generated internally for Attribute table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the `ATTRIBUTE_STRUCTURE` keyword of the [IDLffShape::GetProperty](#) method.

Index

A scalar or array of integers specifying the entity in which you want to set the attributes. If *Index* is a scalar, then it specifies the starting point at which to start writing the attributes as given by the *Value* argument. If *Index* is an array with the same number of elements as *Value*, then *Index* specifies the indices of the attributes to write. When writing new attributes, the attributes must be written in order, starting at index 0, with no gaps. When overwriting existing attributes, the attributes may be written in any order.

Value

If *Attribute_Num* is present, then *Value* is the value (or array of values) of the field within the attribute. If the value is not of the correct type, type conversion is attempted.

If *Attribute_Num* is not present, then *Value* is an *Attribute* structure (or array of structures) whose fields match the fields in the attribute table. The type of this *Attribute* structure must match the type that is generated internally for *Attribute* table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE_STRUCTURE keyword of the IDLffShape::GetProperty method. If *Value* is an array, the attributes specified in *Index* are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

Keywords

None

Examples

For an example of SetAttributes, see [“Creating New Shapefiles”](#) on page 3510. In this example you will create a new shapefile, define the attributes for the new file, define a new entity, define some attributes, insert the new entity, and then use the SetAttributes method to insert the attributes into the new file.

- [“IDLffXMLDOMTreeWalker”](#) on page 3717

IDLffXMLDOMAttr

The IDLffXMLDOMAttr object represents an attribute that is part of an element object. Typically, the allowable values for the attribute are defined in a DTD.

Attribute objects are subclasses of the [IDLffXMLDOMNode](#) abstract superclass, but are not actually child nodes of the elements they describe and are not considered as part of the DOM tree. Therefore, an attribute object does not have a parent or siblings, and so the `ParentNode()`, `NextSibling()`, and `PreviousSibling()` methods always return a null object reference. The DOM takes the view that attributes are properties of elements, rather than having a separate identity.

An attribute's value may be explicitly assigned or may take on a default value as described by a DTD. If neither of these alternatives is true, the attribute does not exist in the element. Use the [IDLffXMLDOMAttr::GetSpecified](#) method to determine if the value was explicitly specified or has taken on the default value.

If the value of an attribute may contain entity references, then the attribute node may have either text or entity-reference child nodes.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMAttr::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMAttr::Cleanup](#)
- [IDLffXMLDOMAttr::GetName](#)
- [IDLffXMLDOMAttr::GetSpecified](#)
- [IDLffXMLDOMAttr::GetValue](#)

- [IDLffXMLDOMAttr::Init](#)
- [IDLffXMLDOMAttr::SetValue](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMAttr Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

IDLffXMLDOMAttr::Cleanup

The IDLffXMLDOMAttr::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

-----	------------

IDLffXMLDOMAttr::GetName

The IDLffXMLDOMAttr::GetName function method returns the name of the attribute node.

Syntax

Result = *Obj*->[\[IDLffXMLDOMAttr::\]GetName\(\)](#)

Return Value

Returns a scalar string containing the name of the attribute node.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMAttr::GetSpecified

The IDLffXMLDOMAttr::GetSpecified function method returns a scalar integer indicating how the value of the attribute node was set.

Syntax

Result = *Obj*->[IDLffXMLDOMAttr::]GetSpecified()

Return Value

Returns 1 if the value of the attribute node was explicitly set in the XML document or was set programmatically with the [IDLffXMLDOMAttr::SetValue](#) method. Returns 0 if the attribute's value was established from the default value declared in the document's DTD.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLfXMLDOMAttr::GetValue

The IDLfXMLDOMAttr::GetValue function method returns the value of the attribute node.

Syntax

Result = *Obj*->[IDLfXMLDOMAttr::]GetValue()

Return Value

Returns a scalar string containing the value of the attribute node.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMAttr::Init

The IDLffXMLDOMAttr::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetAttributes](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMAttr::SetValue

The IDLffXMLDOMAttr::SetValue procedure method sets the value of the attribute node, using the *Value* argument.

Syntax

Obj->[IDLffXMLDOMAttr::]SetValue, *Value*

Arguments

Value

A scalar string used to set the value of the attribute node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCDATASection

The IDLffXMLDOMCDATASection object is used to escape blocks of text containing characters that would otherwise be regarded as markup. The only delimiter that is recognized in a CDATA section is the “[>]” string that ends the CDATA section. CDATA sections cannot be nested. The primary purpose is for including material such as XML fragments without needing to escape all the delimiters.

There are no methods specific to this class except Cleanup and Init.

Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

[IDLffXMLDOMText](#)

Creation

See [IDLffXMLDOMCDATASection::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMCDATASection::Cleanup](#)
- [IDLffXMLDOMCDATASection::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLffXMLDOMCDATASection::Init

The IDLffXMLDOMCDATASection::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMCharacterData

The IDLffXMLDOMCharacterData class extends the [IDLffXMLDOMNode](#) class with a set of methods for accessing character data in the DOM tree. This is an abstract class in the sense that there will never be an instance of this class, but its methods are available to its subclasses.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMCharacterData::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMCharacterData::AppendData](#)
- [IDLffXMLDOMCharacterData::Cleanup](#)
- [IDLffXMLDOMCharacterData::DeleteData](#)
- [IDLffXMLDOMCharacterData::GetData](#)
- [IDLffXMLDOMCharacterData::GetLength](#)
- [IDLffXMLDOMCharacterData::Init](#)
- [IDLffXMLDOMCharacterData::InsertData](#)
- [IDLffXMLDOMCharacterData::ReplaceData](#)
- [IDLffXMLDOMCharacterData::SetData](#)
- [IDLffXMLDOMCharacterData::SubstringData](#)

In addition, this class inherits the methods of any superclasses.

Version History

IDLffXMLDOMCharacterData Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

IDLffXMLDOMCharacterData::AppendData

The IDLffXMLDOMCharacterData::AppendData procedure method appends a string to the character data in the node.

Syntax

Obj->[IDLffXMLDOMCharacterData::]AppendData, *String*

Arguments

String

A scalar string to be added at the end of the character data.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::Cleanup

The IDLffXMLDOMCharacterData::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::DeleteData

The IDLffXMLDOMCharacterData::DeleteData procedure method deletes a number of characters from the character data in the node, starting at an offset.

Syntax

Obj->[IDLffXMLDOMCharacterData::]DeleteData, *Offset*, *Count*

Arguments

Offset

A scalar value that indicates where to begin deleting characters.

Count

A scalar number of characters to delete.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::GetData

The IDLffXMLDOMCharacterData::GetData function method returns the character data in the node.

Syntax

Result = *Obj*->[IDLffXMLDOMCharacterData::]GetData()

Return Value

Returns a scalar string containing the character data in the node.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::GetLength

The IDLffXMLDOMCharacterData::GetLength function method returns the number of characters in the node.

Syntax

Result = *Obj*->[IDLffXMLDOMCharacterData::]GetLength()

Return Value

Returns a scalar string containing the number of characters in the node. This value may be zero.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::Init

The IDLffXMLDOMCharacterData::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMCharacterData::InsertData

The IDLffXMLDOMCharacterData::InsertData procedure method inserts a string in the node's character data at a specified offset.

Syntax

Obj->[IDLffXMLDOMCharacterData::]InsertData, *Offset*, *String*

Arguments

Offset

A scalar value that indicates where in the character data to begin inserting the string contained in *String*.

String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::ReplaceData

The IDLffXMLDOMCharacterData::ReplaceData procedure method replaces a number of characters, starting at an offset in the node's character data, with a string.

Syntax

Obj->[IDLffXMLDOMCharacterData::]ReplaceData, *Offset*, *Count*, *String*

Arguments

Offset

A scalar value that indicates where in the character data to begin replacement.

Count

A scalar number of characters in the character data to replace.

String

A scalar string to be inserted in the character data at the point indicated by *Offset*.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::SetData

The IDLffXMLDOMCharacterData::SetData procedure method sets the node's character data to a string.

Syntax

Obj->[IDLffXMLDOMCharacterData::SetData](#), *String*

Arguments

String

A scalar string to be set in the node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMCharacterData::SubstringData

The IDLffXMLDOMCharacterData::SubstringData function method returns a string composed of a substring of the node's character data.

Syntax

Result = *Obj*->[IDLffXMLDOMCharacterData:]SubstringData(*Offset*, *Count*)

Return Value

Returns a string containing a substring of the node's character data that starts at *Offset* and has a length specified by *Count*.

Arguments

Offset

A scalar value that indicates where in the character data to begin the substring.

Count

A scalar length of the substring.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMComment

The IDLffXMLDOMComment class represents the content of a comment, the characters between the starting “<!--” and the ending “-->”.

There are no methods specific to this class except Cleanup and Init.

Superclasses

[IDLffXMLDOMNode](#)

[IDLffXMLDOMCharacterData](#)

Creation

See [IDLffXMLDOMComment::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMComment::Cleanup](#)
- [IDLffXMLDOMComment::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMComment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)
- [IDLffXMLDOMCharacterData](#)

IDLffXMLDOMComment::Cleanup

The IDLffXMLDOMComment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

IDLffXMLDOMComment::Init

The IDLffXMLDOMComment::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMDocument

The IDLffXMLDOMDocument class represents the entire XML document as the root of the document tree and by providing the primary access to the document's data.

This class is also the class factory for DOM tree nodes such as [IDLffXMLDOMText](#) since all DOM tree nodes must belong to a specific document. To this end, this class includes methods that create DOM tree nodes of all the various types.

Note that nodes created with these factory methods belong to the document, but are not part of the DOM tree structure until they are inserted into the DOM tree. See the relevant methods in the [IDLffXMLDOMNode](#) class for details on inserting nodes into the DOM tree.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMDocument::Init](#).

Properties

Objects of this class have the following properties. See “[IDLffXMLDOMDocument Properties](#)” on page 3574 for details on individual properties.

- [NODE_DESTRUCTION_POLICY](#)

Methods

This class has the following methods:

- [IDLffXMLDOMDocument::Cleanup](#)
- [IDLffXMLDOMDocument::CreateAttribute](#)
- [IDLffXMLDOMDocument::CreateCDATASection](#)
- [IDLffXMLDOMDocument::CreateComment](#)
- [IDLffXMLDOMDocument::CreateElement](#)

- [IDLffXMLDOMDocument::Init](#)
- [IDLffXMLDOMDocument::Load](#)
- [IDLffXMLDOMDocument::Save](#)
- [IDLffXMLDOMDocument::SetProperty](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
6.2	Added <code>NODE_DESTRUCTION_POLICY</code> property. Added <code>CreateNodeIterator</code> , <code>CreateTreeWalker</code> , <code>GetProperty</code> and <code>SetProperty</code> methods.

IDLffXMLDOMDocument Properties

IDLffXMLDOMDocument objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffXMLDOMDocument::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffXMLDOMDocument::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffXMLDOMDocument::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [NODE_DESTRUCTION_POLICY](#)

In addition, objects of this class inherit properties from the following superclass:

- [IDLffXMLDOMNode](#)

NODE_DESTRUCTION_POLICY

A scalar integer that specifies the node destruction policy for all node objects created directly or indirectly by a document object. The property value is not changed if you attempt to set it to other than one of the supported values:

0	When OBJ_DESTROY destroys a node object, it also destroys all node objects that the node created. These nodes, in turn, destroy all the nodes that they created, and so on. This is the default property value.
1	OBJ_DESTROY destroys only the node object for which it is called.

The destruction policy used for node destruction is obtained from the document object's property at the time a node object is destroyed. Thus, the document object's node destruction policy property can be changed between node destructions to use a specific destruction policy for certain nodes.

For all values of this property, all of the nodes created directly or indirectly by the document object are destroyed when the document object itself is destroyed.

For example, consider the following code:

```
oChild = oElement->getFirstChild()
oParent = oElement->getParentNode()
OBJ_DESTROY, oElement
```

If `NODE_DESTRUCTION_POLICY` has a value of 0 when `OBJ_DESTROY` is called, all three nodes, `oChild`, `oParent`, and `oElement`, are destroyed. If the property has a value of 1 when `OBJ_DESTROY` is called, only `oElement` is destroyed.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffXMLDOMDocument::Cleanup

The IDLffXMLDOMDocument::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffXMLDOMDocument::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateAttribute

The IDLffXMLDOMDocument::CreateAttribute function method creates and names an attribute node that is owned by the document. The new attribute can be set in an Element node with the [IDLffXMLDOMElement::SetAttributeNode](#) method.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateAttribute(*Name*)

Return Value

Returns an object reference to the new [IDLffXMLDOMAttr](#) node.

Arguments

Name

A scalar string containing the attribute name.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateCDATASection

The IDLffXMLDOMDocument::CreateCDATASection function method creates a CDATASection node that is owned by the document and stores a string in the CDATASection node.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateCDATASection(*String*)

Return Value

Returns an object reference to the new [IDLffXMLDOMCDATASection](#) node.

Arguments

String

A scalar string to put in the new CDATASection node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateComment

The IDLffXMLDOMDocument::CreateComment function method creates a comment node that is owned by the document and stores a string in the comment node.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateComment(*String*)

Return Value

Returns an object reference to the new IDLffXMLDOMComment node.

Arguments

String

A scalar string to put in the new comment node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateDocumentFragment

The IDLffXMLDOMDocument::CreateDocumentFragment function method creates a document-fragment node that is owned by the document.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateDocumentFragment()

Return Value

Returns an object reference to the new [IDLffXMLDOMDocumentFragment](#) node.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateElement

The IDLffXMLDOMDocument::CreateElement function method creates an element node that is owned by the document and sets the element's name to a tag name.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateElement(*TagName*)

Return Value

Returns an object reference to the new IDLffXMLDOMElement node.

Arguments

TagName

A scalar string that contains the name of the element.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateEntityReference

The IDLffXMLDOMDocument::CreateEntityReference function method creates and names an entity reference node that is owned by the document.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateEntityReference(*Name*)

Return Value

Returns an object reference to the new [IDLffXMLDOMEntityReference](#) node.

Arguments

Name

A scalar string that contains the entity reference name.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateNodeIterator

The `IDLffXMLDOMDocument::CreateNodeIterator` function method is used to create an instance of an [IDLffXMLDOMNodeIterator](#) object. This function returns an object reference to that instance.

Please note the following exceptions in node iteration:

- Attributes are never children of DOM nodes, so they are not visited by the node iterator. Showing attributes is only meaningful when the iterator root node is an attribute.
- Entities are not part of the DOM tree, so they are not visited by the node iterator. Showing entities is only meaningful when the iterator root node is an entity.
- Notations are not part of the DOM tree, so they are not visited by the node iterator. Showing notations is only meaningful when the iterator root node is a notation.

Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateNodeIterator( RootNode  
    [, FILTER_NAME=string] [, FILTER_USERDATA=variable]  
    [, WHAT_TO_SHOW=value] )
```

Arguments

RootNode

An object reference to an object that is a subclass of [IDLffXMLDOMNode](#) that refers to a node in the DOM tree. The iterator's current position is set immediately before this node. If this object reference is `NULL`, the iterator's current position is set immediately before the document node.

Keywords

FILTER_NAME

Set this keyword to a scalar string containing the name of an IDL function that is called each time the iterator is about to visit a node. The purpose of this function is to allow the iterator to ask the IDL application if it should visit a particular node, and hence return it in response to an [IDLffXMLDOMNodeIterator::NextNode](#) or

`IDLffXMLDOMNodeIterator::PreviousNode` method call. The code in this function should analyze the incoming node and then return a value that instructs the iterator to accept or reject the node.

If this keyword is not specified, the node iterator visits every node.

Nodes that are accepted are returned by `IDLffXMLDOMNodeIterator::NextNode` and `IDLffXMLDOMNodeIterator::PreviousNode`. Nodes that are rejected are not returned by these methods.

The filter function is called by the iterator for the given node after the determinations are made with respect to the `WHAT_TO_SHOW` setting. Therefore, the filter function is not called for nodes that are rejected by the `WHAT_TO_SHOW` property.

The filter function specified by `FILTER_NAME` must have the following parameters:

- **Node Object** — an object reference to an instance of an `IDLffXMLDOMNode` subclass. This parameter is required and is supplied by the iterator on every call.
- **USERDATA** — an optional keyword parameter set by the iterator to a variable containing a copy of the data provided in the `FILTER_USERDATA` keyword. If `FILTER_USERDATA` is not specified, `USERDATA` is not passed by the iterator.

The function must return one of three scalar integer values:

Value	Function
1	ACCEPT: this node is visited by the node iterator
2	REJECT: this node is not visited by the node iterator
3	SKIP: this node is not visited by the node iterator (same as REJECT)

Table 30-19: Return Values for CreateNodeIterator's Filter Function

SKIP and REJECT have the same meanings for a node iterator, but have different meanings for a tree walker. This makes it possible for a single filter function to be used with either a node iterator or tree walker. If the function returns a value that is not supported, the iterator visits the node, as if the return value was 1 (ACCEPT). If the function returns a value that cannot be converted to a scalar, IDL throws an error.

The function should not destroy the node object passed as the first parameter.

FILTER_USERDATA

Set this keyword to an IDL variable containing data to pass to the filter function each time the iterator calls the filter function. The iterator creates a copy of this variable to pass on each call.

Supplying this keyword without [FILTER_NAME](#) produces no effect on the iterator.

WHAT_TO_SHOW

Set this keyword to a scalar unsigned integer containing a bitmask, where each bit indicates types of nodes that the iterator visits. If this keyword is not specified, the node iterator visits every node.

Type	Value (Hex)	Value (Decimal)
ALL	'ffff'xu	65535U
Element	'0001'xu	1U
Attribute	'0002'xu	2U

Document Fragment	'0400'xu	1024U
Notation	'0800'xu	2048U

Table 30-20: Bitmasks for CreateNodeIterator's WHAT_TO_SHOW Keyword

The node iterator performs the WHAT_TO_SHOW test for a node before calling any user-provided filter function.

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMDocument::CreateProcessingInstruction

The IDLffXMLDOMDocument::CreateProcessingInstruction function method creates a processing-instruction node that is owned by the document and stores two strings in the processing-instruction node.

Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateProcessingInstruction( Target,  
    Data )
```

Return Value

Returns an object reference to the new [IDLffXMLDOMProcessingInstruction](#) node.

Arguments

Target

A scalar string to store in the processing-instruction target.

Data

A scalar string to store in the processing-instruction data.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateTextNode

The IDLffXMLDOMDocument::CreateTextNode function method creates a text node that is owned by the document and stores a string in the text node.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]CreateTextNode(*String*)

Return Value

Returns an object reference to the new IDLffXMLDOMText node.

Arguments

String

A scalar string to put in the new text node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::CreateTreeWalker

The `IDLffXMLDOMDocument::CreateTreeWalker` function method is used to create an instance of an `IDLffXMLDOMTreeWalker` object. This function returns an object reference to that instance.

Please note the following exceptions in tree-walking:

- Attributes are never children of DOM nodes, so they are not visited by the tree walker. Showing attributes is only meaningful when the walker root node is an attribute.
- Entities are not part of the DOM tree, so they are not visited by the tree walker. Showing entities is only meaningful when the walker root node is an entity.
- Notations are not part of the DOM tree, so they are not visited by the tree walker. Showing notations is only meaningful when the walker root node is a notation.

Syntax

```
Result = Obj->[IDLffXMLDOMDocument::]CreateTreeWalker( RootNode  
    [, FILTER_NAME=string] [, FILTER_USERDATA=variable]  
    [, WHAT_TO_SHOW=value] )
```

Arguments

RootNode

An object reference to an object that is a subclass of `IDLffXMLDOMNode` that refers to a node in the DOM tree. The tree walker's current position is set at this node. If the object reference is NULL, the walker's current position is set to the document node.

Keywords

FILTER_NAME

Set this keyword to a scalar string containing the name of an IDL function that is called each time the tree walker is about to visit a node. The purpose of this function is to allow the walker to ask the IDL application if it should visit a particular node, and hence return it in response to a call to one of the tree walker's navigation methods (e.g., `IDLffXMLDOMTreeWalker::NextNode`). The code in this function should

analyze the incoming node and then return a value that instructs the walker to accept or reject the node.

If this keyword is not specified, the tree walker visits every node.

The various tree-walker movement methods return nodes that are accepted by the filter function. The movement methods do not return nodes that are rejected or skipped by the filter function. The walker does not consider nodes that are children of a rejected node, but does consider children of nodes that are skipped.

The tree walker calls the filter function for the given node after making determinations with respect to the **WHAT_TO_SHOW** setting. However, unlike the node iterator, the walker still calls the filter function for nodes not meeting the **WHAT_TO_SHOW** criteria. This is required so that the filter function can direct the walker to either REJECT or SKIP a node whose type is not in the **WHAT_TO_SHOW** list. If the filter function returns ACCEPT for a node not meeting the **WHAT_TO_SHOW** criteria, the walker SKIPS the node. That is, a filter function cannot override the rejection of a node because of the **WHAT_TO_SHOW** setting; it can only direct the walker to REJECT or SKIP such a node.

The filter function specified by **FILTER_NAME** must have the following parameters:

- **Node Object** — an object reference to an instance of an **IDLffXMLDOMNode** subclass. This parameter is required and is supplied by the tree walker on every call.
- **USERDATA** — an optional keyword parameter set by the tree walker to a variable containing a copy of the data provided in the **FILTER_USERDATA** keyword. If **FILTER_USERDATA** is not specified, **USERDATA** is not passed by the walker.

The function must return one of three scalar integer values:

Value	Function
1	ACCEPT: the tree walker visits this node
2	REJECT: the tree walker does not visit this node or its children
3	SKIP: the tree walker does not visit this node, but considers the node's children for visiting

Table 30-21: Return Values for CreateTreeWalker's Filter Function

If the function returns a value that is not supported, the tree walker visits the node, as if the return value were 1 (ACCEPT). If the function returns a value that cannot be converted to a scalar, IDL throws an error.

The function should not destroy the node object passed as the first parameter.

FILTER_USERDATA

Set this keyword to an IDL variable containing data to pass to the filter function each time the tree walker calls the filter function.

Supplying this keyword without [FILTER_NAME](#) produces no effect on the tree walker.

WHAT_TO_SHOW

Set this keyword to a scalar unsigned integer containing a bitmask, where each bit indicates types of nodes that the tree walker visits. If this keyword is not specified, the walker visits every node.

Type	Value (Hex)	Value (Decimal)
ALL	'ffff'xu	65535U
Element	'0001'xu	1U

Notation	'0800'xu	2048U

Table 30-22: Bitmasks for CreateTreeWalker's WHAT_TO_SHOW Keyword

The tree walker performs the `WHAT_TO_SHOW` test for a node before calling any user-provided filter function.

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMDocument::GetDoctype

The IDLffXMLDOMDocument::GetDoctype function method creates an instance of [IDLffXMLDOMDocumentType](#) and returns its object reference.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]GetDoctype()

Return Value

Returns an object reference to the new instance of [IDLffXMLDOMDocumentType](#), or a null object reference if a document does not have a DTD.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::GetDocumentElement

The IDLffXMLDOMDocument::GetDocumentElement function method creates an instance of an [IDLffXMLDOMElement](#) and returns its object reference. The IDLffXMLDOMElement object refers to the node that is the root element of the document.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]GetDocumentElement()

Return Value

Returns an object reference to the new instance of [IDLffXMLDOMElement](#).

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::GetElementsByTagName

The `IDLffXMLDOMDocument::GetElementsByTagName` function method creates an `IDLffXMLDOMNodeList` object containing all element nodes in the document tree with the specified tag name and returns an object reference to the `IDLffXMLDOMNodeList` object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

Syntax

Result = *Obj*->[IDLffXMLDOMDocument::]GetElementsByTagName(*TagName*)

Return Value

Returns an object reference to the `IDLffXMLDOMNodeList` object.

The returned node list is “live,” in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an `IDLffXMLDOMNodeList` object is still returned, but contains no nodes.

Arguments

TagName

A scalar string containing the tag name that is used to match the elements. The value “*” matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocument::GetProperty

The IDLffXMLDOMDocument::GetProperty procedure method is used to get the values of various properties of the document object.

Syntax

Obj->[IDLffXMLDOMDocument::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLffXMLDOMDocument Properties” on page 3574 that contains the word “Yes” in the “Get” column of the property table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMDocument::Init

The IDLffXMLDOMDocument::Init function method initializes the object. It can also load and parse an XML document, using the same keywords that [IDLffXMLDOMDocument::Load](#) does. (For more information on loading, see that method's description.)

Syntax

```
Obj = OBJ_NEW('IDLffXMLDOMDocument'
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]
  [, /EXPAND_ENTITY_REFERENCES]
  [, FILENAME=string / STRING=string] [, MSG_ERROR=string]
  [, MSG_FATAL=string] [, MSG_WARNING=string] [, /QUIET]
  [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value])
```

or

```
Result = Obj->[IDLffXMLDOMDocument::]Init(
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]
  [, /EXPAND_ENTITY_REFERENCES]
  [, FILENAME=string / STRING=string] [, MSG_ERROR=string]
  [, MSG_FATAL=string] [, MSG_WARNING=string] [, /QUIET]
  [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value] ) (In a
  lifecycle method only.)
```

Return Value

Returns an object reference to the newly created object when this method is called indirectly, as part of the call to the OBJ_NEW function.

Returns 1 if initialization was successful or 0 otherwise, when this method is called directly within a subclass Init method.

Arguments

None

Keywords

Note

Any property listed under “[IDLfXMLDOMDocument Properties](#)” on page 3574 that contains the word “Yes” in the “Init” column of the property table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

EXCLUDE_IGNOREABLE_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM tree. Note that in order for the parser to distinguish between ignorable and non-ignorable white space, validation must be turned on with the [VALIDATION_MODE](#) keyword and there must be a DTD. This keyword has no effect if [VALIDATION_MODE](#) is 0 or if there is no DTD for the XML document.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

FILENAME

Set this keyword to a scalar string containing the name of the XML file to load and parse.

The FILENAME keyword can also specify a URL. In this case, the object reads the XML data from the specified URL over the network and builds the document tree without the XML data needing to be present in a local file.

Setting both the FILENAME and STRING keywords causes an error.

The following example reads XML from an RSS feed containing weather information for Denver, Colorado:

```
FUNCTION filter, oNode
    name = oNode->getNodeName()
```

```

        IF name EQ 'title' OR name EQ 'description' THEN $
            RETURN, 1 ; accept
        RETURN, 3 ;; skip
    END

    PRO weather
        oDoc = OBJ_NEW( 'IDLffXMLDOMDocument', $
            FILENAME='http://weather.gov/data/current_obs/KDEN.rss' )
        oNodeIterator = oDoc->createNodeIterator( OBJ_NEW(), $
            FILTER_NAME='filter' )

        oNode = oNodeIterator->nextNode()
        WHILE OBJ_VALID( oNode ) DO BEGIN
            ; Assuming only one text node per element
            PRINT, (oNode->GetFirstChild())->getNodeValue()
            oNode = oNodeIterator->nextNode()
        ENDWHILE
        PRINT
        OBJ_DESTROY, oDoc
    END

```

MSG_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- Filename – A scalar string containing the name of the file being parsed
- Line number – A scalar integer containing the line number in the file where the parsing error occurred
- Column number – A scalar integer containing the column number in the file where the parsing error occurred
- Message – A scalar string containing the parser error message

MSG_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for [MSG_ERROR](#).

MSG_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for [MSG_ERROR](#).

QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

SCHEMA_CHECKING

Set this keyword to an integer value to indicate the type of validation the parser should perform. XML schemas describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation occurs. Possible values are:

0	No schema checking is performed.
1	Schema checking is performed only if a schema is provided. This is the default value.
2	Full schema constraint checking is performed if a schema is provided. This feature checks the schema grammar itself for additional errors.

STRING

Set this keyword equal to a scalar string containing the XML Document text. Setting the `STRING` keyword avoids the need for file input/output operations. As a result, setting both the `FILENAME` and `STRING` keywords causes an error.

If the XML Document text contains references to local files, IDL's current working directory should be set to the directory containing those files. To avoid the need to manage the current working directory, use this keyword with self-contained XML documents. For example, placing DTD information in a `DOCTYPE` element in the document text avoids the need for an external file reference.

VALIDATION_MODE

Set this keyword to one of the following values:

0	The parser does not report validation errors.
1	The parser reports validation errors only if a DTD is specified. This is the default value.
2	The parser always reports validation errors.

This keyword ignores all other values.

Version History

6.1	Introduced
6.2	Added SCHEMA_CHECKING keyword
6.4	Added STRING keyword

IDLffXMLDOMDocument::Load

The IDLffXMLDOMDocument::Load procedure method loads XML data from the source specified by the **FILENAME** keyword. The XML parser then parses the data, using any related DTD or schema specifications. The results of the parse are used to construct a DOM document tree that can then be accessed through this document object.

If the **FILENAME** keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

Note

This method invalidates all object references to node objects created with the previous document.

IDL issues messages for any parser warnings or errors unless the **QUIET** keyword is set. If a parsing error that is more severe than a warning is encountered during parsing, IDL issues a single additional message after parsing and returns to the interpreter, even if **QUIET** is set. The IDL CATCH facility can intercept this message. If this message is issued, the document tree is empty, containing no nodes.

Syntax

```
Obj->[IDLffXMLDOMDocument::]Load
  [, /EXCLUDE_IGNOREABLE_WHITESPACE]
  [, /EXPAND_ENTITY_REFERENCES]
  [, FILENAME=string / STRING=string] [, MSG_ERROR=string]
  [, MSG_FATAL=string] [, MSG_WARNING=string] [, /QUIET]
  [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value]
```

Arguments

None

Keywords

EXCLUDE_IGNOREABLE_WHITESPACE

Set this keyword to prevent text nodes containing ignorable white space from being inserted into the DOM tree. The default action is to include these nodes in the DOM

tree. Note that in order for the parser to distinguish between ignorable and non-ignorable white space, validation must be turned on with the `VALIDATION_MODE` keyword and there must be a DTD. This keyword has no effect if `VALIDATION_MODE` is 0 or if there is no DTD for the XML document.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text. If entity references are not expanded, the DOM parser creates entity-reference nodes in the DOM tree. The children of the entity-reference nodes are read-only and are elements containing the entity values. If entity references are expanded, the DOM parser creates no entity-reference nodes in the DOM tree and instead creates read-write nodes that correspond to the fully expanded substitution text.

FILENAME

Set this keyword equal to a scalar string containing the name of the XML file to load and parse. If this keyword is not specified, the other keywords have no effect and the DOM document tree is unchanged. If it is specified, then any existing DOM document tree is destroyed, and the results of the parsing operation are used to create a new DOM document tree.

The keyword string can also specify a URL. In this case, the object reads the XML data from the specified URL over the network and builds the document tree without the XML data needing to be present in a local file.

Setting both the `FILENAME` and `STRING` keywords causes an error.

The following example reads XML from an RSS feed containing weather information for Denver, Colorado:

```

FUNCTION filter, oNode
    name = oNode->getNodeName()
    IF name EQ 'title' OR name EQ 'description' THEN $
        RETURN, 1 ; accept
    RETURN, 3 ;; skip
END

PRO weather
    oDoc = OBJ_NEW( 'IDLffXMLDOMDocument', $
        FILENAME='http://weather.gov/data/current_obs/KDEN.rss' )
    oNodeIterator = oDoc->createNodeIterator( OBJ_NEW(), $
        FILTER_NAME='filter' )

    oNode = oNodeIterator->nextNode()
    WHILE OBJ_VALID( oNode ) DO BEGIN

```

```

        ; Assuming only one text node per element
        PRINT, (oNode->GetFirstChild())->getNodeValue()
        oNode = oNodeIterator->nextNode()
    ENDWHILE
PRINT
OBJ_DESTROY, oDoc
END

```

MSG_ERROR

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates an error message. The following procedure parameters are required:

- **Filename** – A scalar string containing the name of the file being parsed
- **Line number** – A scalar integer containing the line number in the file where the parsing error occurred
- **Column number** – A scalar integer containing the column number in the file where the parsing error occurred
- **Message** – A scalar string containing the parser error message

MSG_FATAL

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a fatal error message. The required procedure parameters are the same as for [MSG_ERROR](#).

MSG_WARNING

Set this keyword to a scalar string that contains the name of an IDL procedure that will be called when the parser generates a warning message. The required procedure parameters are the same as for [MSG_ERROR](#).

QUIET

Set this keyword to prevent IDL from printing out informational parser warnings and error messages. The default action is to report all parser warnings and errors with messages. If an error more severe than a warning is encountered, IDL issues an additional single message after parsing is complete and returns to the interpreter, regardless of this keyword's setting.

SCHEMA_CHECKING

Set this keyword to an integer value to indicate the type of validation the parser should perform. XML schemas describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation occurs.

Possible values are:

0	No schema checking is performed.
1	Schema checking is performed only if a schema is provided. This is the default value.
2	Full schema constraint checking is performed if a schema is provided. This feature checks the schema grammar itself for additional errors.

STRING

Set this keyword equal to a scalar string containing the XML Document text. Setting the STRING keyword avoids the need for file input/output operations. As a result, setting both the FILENAME and STRING keywords causes an error.

If the XML Document text contains references to local files, IDL's current working directory should be set to the directory containing those files. To avoid the need to manage the current working directory, use this keyword with self-contained XML documents. For example, placing DTD information in a DOCTYPE element in the document text avoids the need for an external file reference.

VALIDATION_MODE

Set this keyword to one of the following values:

0	The parser does not report validation errors.
1	The parser reports validation errors only if a DTD is specified. This is the default value.
2	The parser always reports validation errors.

This keyword ignores all other values.

Version History

6.2	Added SCHEMA_CHECKING keyword
6.4	Added STRING keyword

IDLffXMLDOMDocument::Save

The IDLffXMLDOMDocument::Save procedure method serializes the current DOM document belonging to this document object and writes it to the output source specified by the [FILENAME](#) keyword.

Syntax

```
Obj->[IDLffXMLDOMDocument::]Save [, ENCODING=string]  
    [, /EXPAND_ENTITY_REFERENCES]  
    [, FILENAME=string / STRING=variable] [, /PRETTY_PRINT]
```

Arguments

None

Keywords

ENCODING

Set this keyword to a scalar string specifying the encoding to be used when the XML DOM document is written to a file. If this keyword is not specified and the document was loaded with the [IDLffXMLDOMDocument::Init](#) or [IDLffXMLDOMDocument::Load](#) methods from a file, the document is written to a file using the same encoding used to load the file. If this keyword is not specified and the document was created programatically, the document is written to the file using UTF-8 encoding.

Note

For the list of supported XML encodings, see [“About XML”](#) (Chapter 20, *Application Programming*).

If an encoding is specified that is not supported, no error is reported and this method writes an empty file.

EXPAND_ENTITY_REFERENCES

Set this keyword to cause the parser to replace entity references with their fully expanded substitution text as the DOM tree is written to the output file. The DOM tree itself is not changed. The default behavior is to write the entity references to the output file.

FILENAME

Set this keyword to the name of the XML file in which to store the XML data. If FILENAME is not set or is set to "" (null string), this method will return without storing any data on the file system.

FILENAME can contain a directory path (e.g., 'C:\ITT\test.xml'). IDL throws an error and stops if any of the following conditions are true:

- The directory does not exist
- The directory exists, but is not writable
- The file exists, but is not writable

Setting both the FILENAME and STRING keywords causes an error.

PRETTY_PRINT

Set this keyword to format the output by adding white space to produce a pretty-printed, indented, reader-friendly form.

STRING

Set this keyword to a named variable that will contain the string data representing the XML DOM document currently represented in this object. Setting the STRING keyword avoids the need for file input/output operations. As a result, setting the FILENAME and STRING keywords causes an error.

Version History

6.1	Introduced
6.2	Added ENCODING keyword
6.4	Added STRING keyword

IDLffXMLDOMDocument:: SetProperty

The IDLffXMLDOMDocument::SetProperty procedure method is used to set the values of various properties of the parser.

Syntax

Obj->[IDLffXMLDOMDocument::]SetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLffXMLDOMDocument Properties” on page 3574 that contains the word “Yes” in the “Set” column of the property table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMDocumentFragment

The `IDLffXMLDOMDocumentFragment` class references a document-fragment node.

It is very common to want to be able to extract a portion of a document's tree or to create a new fragment of a document. Imagine implementing a user command such as “cut” or rearranging a document by moving fragments around. It is desirable to have an object that can hold such fragments, and it is quite natural to use a node for this purpose. While it is true that a document object could fill this role, it can potentially be a heavyweight object, depending on the underlying implementation. What you need for this purpose, instead, is a very lightweight object, and the document-fragment node is such an object.

Furthermore, various operations such as inserting nodes as children of another node may take document-fragment objects as arguments; this results in all the child nodes of the document-fragment node being moved to the child list of this node.

The children of a document-fragment node are zero or more nodes representing the roots of any sub-trees defining the structure of the document. Document-fragment nodes do not need to be well-formed XML documents (although they do need to follow the rules imposed upon well-formed XML parsed entities, which can have multiple root nodes). For example, a document-fragment node might have only one child, and that child node could be a text node. Such a structure model represents neither an HTML document nor a well-formed XML document.

When a document-fragment node is inserted into a document tree (or, indeed, any other node that may take children), the children of the document-fragment node and not the document-fragment node itself are inserted into the node. This insertion process makes the document-fragment node very useful when you want to create nodes that are siblings. Because the document-fragment node acts as the parent of these nodes, you can use the standard methods from the node object, such as `InsertBefore()` and `AppendChild()`.

There are no methods specific to this class except `Cleanup` and `Init`.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMDocumentFragment::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMDocumentFragment::Cleanup](#)
- [IDLffXMLDOMDocumentFragment::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocumentFragment Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

IDLffXMLDOMDocumentFragment::Cleanup

The IDLffXMLDOMDocumentFragment::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

IDLffXMLDOMDocumentType::GetEntities

The IDLffXMLDOMDocumentType::GetEntities function method returns the general entities, both external and internal, declared in the DTD.

Syntax

Result = *Obj*->[IDLffXMLDOMDocumentType::GetEntities\(\)](#)

Return Value

Returns an object reference to a named node map ([IDLffXMLDOMNamedNodeMap](#)) containing the general entities declared in the DTD. If there are no entities, this method returns an empty named node map.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocumentType::GetName

The IDLffXMLDOMDocumentType::GetName function method returns the name of the DTD.

Syntax

Result = *Obj*->[IDLffXMLDOMDocumentType::]GetName()

Return Value

Returns a scalar string containing the name of the DTD (i.e., the name immediately following the DOCTYPE keyword).

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMDocumentType::GetNotations

The IDLffXMLDOMDocumentType::GetNotations function method returns the notations declared in the DTD.

Syntax

Result = *Obj*->[IDLffXMLDOMDocumentType:]GetNotations()

Return Value

Returns an object reference to a named node map (IDLffXMLDOMNamedNodeMap) containing the notations declared in the DTD. If there are no notations, this method returns an empty named node map.

Arguments

None

Keywords

None

Version History

6.1	Introduced

IDLffXMLDOMDocumentType::Init

The IDLffXMLDOMDocumentType::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMEElement

The IDLffXMLDOMEElement class references an element node, which is one of the most common node types in an XML document.

Elements can have attributes associated with them, which can be obtained with the [IDLffXMLDOMNode::GetAttributes](#) method. The IDLffXMLDOMEElement class also has methods for getting an attribute object or an attribute value by its name.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMEElement::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMEElement::Cleanup](#)
- [IDLffXMLDOMEElement::GetAttribute](#)
- [IDLffXMLDOMEElement::GetAttributeNode](#)
- [IDLffXMLDOMEElement::GetElementsByTagName](#)
- [IDLffXMLDOMEElement::GetTagName](#)
- [IDLffXMLDOMEElement::Init](#)
- [IDLffXMLDOMEElement::RemoveAttribute](#)
- [IDLffXMLDOMEElement::RemoveAttributeNode](#)
- [IDLffXMLDOMEElement::SetAttribute](#)
- [IDLffXMLDOMEElement::SetAttributeNode](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMEElement Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLffXMLDOMNode](#)

IDLffXMLDOMELEMENT::Cleanup

The IDLffXMLDOMELEMENT::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMELEMENT::GetAttribute

The IDLffXMLDOMELEMENT::GetAttribute function method returns the value of the attribute specified by *Name*.

Syntax

Result = *Obj*->[IDLffXMLDOMELEMENT::]GetAttribute(*Name*)

Return Value

Returns a scalar string containing the value of the attribute specified by *Name*.

Arguments

Name

A scalar string used to specify the name of the attribute for which to get the value.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMElement::GetAttributeNode

The IDLffXMLDOMElement::GetAttributeNode function method creates an IDLffXMLDOMAttr object and returns its object reference.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]GetAttributeNode(*Name*)

Return Value

Returns an object reference to the IDLffXMLDOMAttr object. The object refers to the attribute node specified by name. If this node does not exist, this function returns a null object reference.

Arguments

Name

A scalar string used to specify the attribute node to get.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMElement::GetElementsByTagName

The `IDLffXMLDOMElement::GetElementsByTagName` function method creates an [IDLffXMLDOMNodeList](#) object containing all descendant element nodes in the document tree with the specified tag name and returns an object reference to the [IDLffXMLDOMNodeList](#) object. The nodes are placed in the node list in the order that they are encountered during a preorder traversal of the tree.

Syntax

Result = *Obj*->[[IDLffXMLDOMElement::](#)]GetElementsByTagName(*TagName*)

Return Value

Returns an object reference to the [IDLffXMLDOMNodeList](#) object.

The returned node list is “live,” in that any changes made to the document tree after the node list was returned will be immediately reflected in the node list.

If no nodes matching the specified tag name are found, an [IDLffXMLDOMNodeList](#) is still returned, but contains no nodes.

Arguments

TagName

A scalar string containing the tag name that is used to match the elements. The value “*” matches all tags only; it is not a wildcard expression, and you cannot use it to make partial matches.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMELEMENT::GetTagName

The IDLffXMLDOMELEMENT::GetTagName function method returns the name of the element.

Syntax

Result = *Obj*->[IDLffXMLDOMELEMENT::]GetTagName()

Return Value

Returns a scalar string containing the name of the element.

Argument

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMELEMENT::Init

The IDLffXMLDOMELEMENT::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMElement::RemoveAttribute

The IDLffXMLDOMElement::RemoveAttribute procedure method removes a specified attribute from the element node.

Syntax

Obj->[IDLffXMLDOMElement::]RemoveAttribute, *Name*

Arguments

Name

A scalar string that contains the name of the attribute to remove from the element.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMElement::RemoveAttributeNode

The IDLffXMLDOMElement::RemoveAttributeNode function method removes a specified attribute node from the element node.

Syntax

Result = *Obj*->[IDLffXMLDOMElement::]RemoveAttributeNode(*OldAttr*)

Return Value

Returns an object reference to an IDLffXMLDOMAttr node referring to the attribute node that was removed.

Arguments

OldAttr

An object reference to an IDLffXMLDOMAttr object that refers to an attribute node to be removed from the element node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMElement::SetAttribute

The IDLffXMLDOMElement::SetAttribute procedure method adds a new attribute to or updates an existing attribute in the element node.

Syntax

Obj->[IDLffXMLDOMElement::]SetAttribute, *Name*, *Value*

Arguments

Name

A scalar string that contains the name of the attribute.

Value

A scalar string that contains the value of the attribute.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMELEMENT::SetAttributeNode

The IDLffXMLDOMELEMENT::SetAttributeNode function method adds an attribute node to the element node.

Syntax

Result = *Obj*->[IDLffXMLDOMELEMENT::]SetAttributeNode(*NewAttr*)

Return Value

Returns an object reference to an IDLffXMLDOMAttr node, if an old attribute is replaced by the new. This method returns a null object reference if no attribute was replaced by this method.

Arguments

NewAttr

An object reference to an IDLffXMLDOMAttr object that refers to an attribute node that is to be set in the element node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMEntity

The IDLffXMLDOMEntity class references an entity, either parsed or unparsed, in an XML document. Entities are placeholders in XML and are inserted into documents by entity references. Entity nodes have no parents. Entity nodes and their descendants are read-only.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMEntity::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMEntity::Cleanup](#)
- [IDLffXMLDOMEntity::GetNotationName](#)
- [IDLffXMLDOMEntity::GetPublicId](#)
- [IDLffXMLDOMEntity::GetSystemId](#)
- [IDLffXMLDOMEntity::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced

IDLfXMLDOMEntity::GetNotationName

The IDLfXMLDOMEntity::GetNotationName function method returns the name of the notation for the entity.

Syntax

Result = *Obj*->[IDLfXMLDOMEntity::]GetNotationName()

Return Value

Returns a scalar string containing the name of the notation for the unparsed entity, or an empty string if the entity is parsed.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMEntity::GetPublicId

The IDLffXMLDOMEntity::GetPublicId function method returns the public ID of the entity, if it is specified.

Syntax

Result = *Obj*->[IDLffXMLDOMEntity:]GetPublicId()

Return Value

Returns a scalar string containing the public ID of the entity, or an empty string if the public ID is not specified.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLfXMLDOMEntity::GetSystemId

The IDLfXMLDOMEntity::GetSystemId function method returns the system ID of the entity, if it is specified.

Syntax

Result = *Obj*->[IDLfXMLDOMEntity::]GetSystemId()

Return Value

Returns a scalar string containing the system ID of the entity, or an empty string if the system ID is not specified.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMEntity::Init

The IDLffXMLDOMEntity::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMDocumentType::GetEntities](#) coupled with [IDLffXMLDOMNamedNodeMap::GetNamedItem](#) are used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMEntityReference

The IDLffXMLDOMEntityReference class references entity reference nodes. Entity references in the source XML file are meant to be substituted by the entity contents upon parsing. Any entity reference nodes left in the document tree may exist because the entity was not found, or the parser was instructed to not expand entity references.

Entity references are read-only.

There are no methods specific to this class except Cleanup and Init.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMEntityReference::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMEntityReference::Cleanup](#)
- [IDLffXMLDOMEntityReference::Init](#)

In addition, this class inherits the methods of any superclasses.

Version History

IDLffXMLDOMEntityReference::Init

The IDLffXMLDOMEntityReference::Init function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNamedNodeMap

The IDLffXMLDOMNamedNodeMap class is a container for nodes (see [IDLffXMLDOMNode](#) and its subclasses) and uses the node's name to access the nodes in the container.

For example, consider this XML:

```
<show title="My Title" date="Nov 12, 1999" author="Me">
```

The entire line is a DOM element node. A `GetAttributes` call returns a `NamedNodeMap` that contains three attribute node objects. The attribute node object containing the date, for example, has a node name of 'date' and a node value of 'Nov 12, 1999'.

The benefit of the named node map is that the nodes are accessed by their node names. Thus, to access the date node, you would use the string 'date' and would not have to worry about its position in the list.

Superclasses

[IDLffXMLDOMNode](#)

Creation

See [IDLffXMLDOMNamedNodeMap::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNamedNodeMap::GetLength

The IDLffXMLDOMNamedNodeMap::GetLength function method returns the number of nodes in the named node map.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]GetLength()

Return Value

Returns an integer containing the number of nodes in the named node map.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNamedNodeMap::GetNamedItem

The IDLffXMLDOMNamedNodeMap::GetNamedItem function method returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied name.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]GetNamedItem(*Name*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied name. If the node is not found, this function returns a null object reference.

Arguments

Name

A scalar string that contains the name used to locate the node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNamedNodeMap::Init

The IDLffXMLDOMNamedNodeMap::Init function method initializes the object, but this class should not be instantiated directly. Instead, the [IDLffXMLDOMNode::GetAttributes](#) method is used to create objects of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNamedNodeMap::Item

The IDLffXMLDOMNamedNodeMap::Item function method returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to an index.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]Item(*Index*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the node from the named node map that corresponds to the supplied index. If the node at the specified index does not exist, a null object reference is returned.

Arguments

Index

An integer that contains the index into the named node map.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNamedNodeMap::RemoveNamedItem

The IDLffXMLDOMNamedNodeMap::RemoveNamedItem function method removes the node from the named node map that corresponds to a name.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]RemoveNamedItem(*Name*)

Return Value

Returns an object reference to an instance of a subclass of [IDLffXMLDOMNode](#) that refers to the removed node if it exists. If the node does not exist, this function returns a null object reference.

Arguments

Name

A scalar string that contains the name used to locate the node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNamedNodeMap::SetNamedItem

The `IDLffXMLDOMNamedNodeMap::SetNamedItem` function method adds a node to the named node map. After adding the node, the node can be accessed using the node's name attribute. If a node with the same name is already present in the map, then the node in the map is replaced by this new node.

Some node types have fixed name tags due to the nature of the node type. For example, an `IDLffXMLDOMText` node's name tag always has the value “#text” because it always contains text in its value tag. For a list of other nodes with fixed name tags see “[IDLffXMLDOMNode::GetNodeName Return Values](#)” on page 3668. (The fixed names are the names in quotation marks.)

Note

You cannot place nodes with fixed name tags into a named node map because it uses the nodes' name tags to search for a requested node.

Syntax

Result = *Obj*->[IDLffXMLDOMNamedNodeMap::]SetNamedItem(*Node*)

Return Value

Returns an object reference to an instance of a subclass of `IDLffXMLDOMNode` that references the node that was replaced, if the method replaces a node in the map. Otherwise, the method returns a null object reference.

Arguments

Node

An object reference to an instance of a subclass of `IDLffXMLDOMNode` that refers to the node to add to the map.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode

The IDLffXMLDOMNode class is an abstract class used as a superclass for other IDLffXMLDOM node classes.

Because this class is an abstract class, there will never be an instance of this class. Rather, this class's functionality described here is accessed through an instance of one of its subclasses.

An object instance of this class is a reference to a corresponding node in the DOM document tree. Use the appropriate methods for this class, defined below, to access and manipulate the DOM data.

This class keeps track of any objects it creates (e.g., via the [IDLffXMLDOMNode::GetFirstChild](#) method) and destroys these objects when it is destroyed.

Superclasses

None

Creation

See [IDLffXMLDOMNode::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMNode::AppendChild](#)
- [IDLffXMLDOMNode::Cleanup](#)
- [IDLffXMLDOMNode::CloneNode](#)
- [IDLffXMLDOMNode::GetAttributes](#)
- [IDLffXMLDOMNode::GetChildNodes](#)
- [IDLffXMLDOMNode::GetFirstChild](#)

- [IDLffXMLDOMNode::GetLastChild](#)
- [IDLffXMLDOMNode::GetNextSibling](#)
- [IDLffXMLDOMNode::GetNodeName](#)
- [IDLffXMLDOMNode::GetNodeType](#)
- [IDLffXMLDOMNode::GetNodeValue](#)
- [IDLffXMLDOMNode::GetOwnerDocument](#)
- [IDLffXMLDOMNode::GetParentNode](#)
- [IDLffXMLDOMNode::GetPreviousSibling](#)
- [IDLffXMLDOMNode::HasChildNodes](#)
- [IDLffXMLDOMNode::Init](#)
- [IDLffXMLDOMNode::InsertBefore](#)
- [IDLffXMLDOMNode::RemoveChild](#)
- [IDLffXMLDOMNode::ReplaceChild](#)
- [IDLffXMLDOMNode::SetNodeValue](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNode::AppendChild

The IDLffXMLDOMNode::AppendChild function method adds a new node to the end of the calling node's children list.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]AppendChild(*NewChild*)

Return Value

Returns an object reference to the new child node.

Arguments

NewChild

An object reference to an instance of an IDLffXMLDOMNode subclass that refers to the node that is being added.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::Cleanup

The IDLffXMLDOMNode::Cleanup procedure method destroys both the object (that is, the accessing object in the IDL tree) and any objects created by that object. It does not modify the actual DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::CloneNode

The IDLffXMLDOMNode::CloneNode function method creates a copy of the calling node (i.e., an instance of an IDLffXMLDOMNode subclass) and returns the object reference to the cloned node. The class of the cloned node is the same as the class of the calling node. The cloned node has no parent.

Cloning an element node copies all attributes and their values and does not copy child nodes unless the **DEEP** keyword is set. Cloning any other type of node simply copies the node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]CloneNode([, /**DEEP**])

Return Value

Returns an object reference to the cloned node.

Arguments

None

Keywords

DEEP

Set this keyword to cause all of a node's children to be cloned along with the calling node. By default, only the calling node is cloned.

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetAttributes

The IDLffXMLDOMNode::GetAttributes function method creates an instance of an [IDLffXMLDOMNamedNodeMap](#) and returns an object reference to that object. The named node map can then be used to access the attributes of an element object.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetAttributes()

Return Value

Returns an object reference to the new [IDLffXMLDOMNamedNodeMap](#) object. If the calling object is not an [IDLffXMLDOMElement](#), a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetChildNodes

The IDLffXMLDOMNode::GetChildNodes function method creates an instance of an [IDLffXMLDOMNodeList](#) object, which can then be used to access the child nodes. If there are no children, the node list object contains no nodes.

The contents of the node list object are updated as changes are made to the tree, such as children being added or removed from the calling node's children list.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetChildNodes()

Return Value

Returns an object reference to the new [IDLffXMLDOMNodeList](#) object.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetFirstChild

The IDLffXMLDOMNode::GetFirstChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the first child of the calling node in the DOM tree. The type of the object corresponds to the type of the first child node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetFirstChild()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetLastChild

The IDLffXMLDOMNode::GetLastChild function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the last child of the calling node in the DOM tree. The type of the object corresponds to the type of the last child node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetLastChild()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a child in the DOM tree. If there are no children, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetNextSibling

The IDLffXMLDOMNode::GetNextSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the next sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the next sibling node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNextSibling()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a next sibling in the DOM tree. If there is no sibling, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetNodeName

The IDLffXMLDOMNode::GetNodeName function method returns the name of the node, depending on the calling node's subclass type.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNodeName()

Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute name
IDLffXMLDOMCDATASection	"#cdata-section"
IDLffXMLDOMComment	"#comment"
IDLffXMLDOMDocument	"#document"
IDLffXMLDOMDocumentFragment	"#document-fragment"
IDLffXMLDOMDocumentType	document type name
IDLffXMLDOMElement	tag name
IDLffXMLDOMEntity	entity name
IDLffXMLDOMEntityReference	name of entity reference
IDLffXMLDOMNotation	notation name
IDLffXMLDOMProcessingInstruction	target
IDLffXMLDOMText	"#text"

Table 30-23: IDLffXMLDOMNode::GetNodeName Return Values

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetNodeType

The IDLffXMLDOMNode::GetNodeType function method returns the subclass type of the calling node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNodeType()

Return Value

Returns an integer whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	2
IDLffXMLDOMCDATASection	4
IDLffXMLDOMComment	8
IDLffXMLDOMDocument	9
IDLffXMLDOMDocumentFragment	11
IDLffXMLDOMDocumentType	10
IDLffXMLDOMElement	1
IDLffXMLDOMEntity	6
IDLffXMLDOMEntityReference	5
IDLffXMLDOMNotation	12
IDLffXMLDOMProcessingInstruction	7
IDLffXMLDOMText	3

Table 30-24: IDLffXMLDOMNode::GetNodeType Return Values

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetNodeValue

The IDLffXMLDOMNode::GetNodeValue function method returns the value of the calling node, depending on its subclass type.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetNodeValue()

Return Value

Returns a scalar string whose value depends on the subclass type:

Subclass	Return Value
IDLffXMLDOMAttr	attribute value
IDLffXMLDOMCDATASection	content of the CDATA section
IDLffXMLDOMComment	content of the comment
IDLffXMLDOMDocument	empty string
IDLffXMLDOMDocumentFragment	empty string
IDLffXMLDOMDocumentType	empty string
IDLffXMLDOMEElement	empty string
IDLffXMLDOMEntity	empty string
IDLffXMLDOMEntityReference	empty string
IDLffXMLDOMNotation	empty string
IDLffXMLDOMProcessingInstruction	entire content excluding the target
IDLffXMLDOMText	content of the text node

Table 30-25: IDLffXMLDOMNode::GetNodeValue Return Values

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetOwnerDocument

The IDLffXMLDOMNode::GetOwnerDocument function method returns an object reference to the [IDLffXMLDOMDocument](#) used to create the node.

Syntax

Result = *Obj*->[IDLffXMLDOMNode::]GetOwnerDocument()

Return Value

Returns an object reference to the [IDLffXMLDOMDocument](#) used to create the node. If the calling node is an [IDLffXMLDOMDocument](#), the method returns a null object reference.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetParentNode

The `IDLffXMLDOMNode::GetParentNode` function method creates an instance of one of the `IDLffXMLDOMNode` subclasses and returns an object reference to that object, which refers to the parent node in the DOM tree. The type of the created object corresponds to the type of the parent node.

All node classes except [IDLffXMLDOMAttr](#), [IDLffXMLDOMDocument](#), [IDLffXMLDOMDocumentFragment](#), and [IDLffXMLDOMEntity](#) may have parents.

A node that has just been created and not yet added to the tree does not have a parent.

Syntax

```
Result = Obj->[IDLffXMLDOMNode::]GetParentNode()
```

Return Value

Returns an object reference to the new object, which refers to the calling node's parent in the DOM tree. The type of the new object corresponds to the type of the parent node. If there is no parent, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::GetPreviousSibling

The IDLffXMLDOMNode::GetPreviousSibling function method creates an instance of one of the IDLffXMLDOMNode subclasses and returns an object reference to that object, which refers to the previous sibling of the calling node in the DOM tree. The type of the object corresponds to the type of the previous sibling node.

Syntax

Result = *Obj*->[\[IDLffXMLDOMNode::\]](#)GetPreviousSibling()

Return Value

Returns an object reference to the new IDLffXMLDOMNode subclass object if there is a previous sibling in the DOM tree. If there is no sibling, a null object reference is returned.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::HasChildNodes

The IDLffXMLDOMNode::HasChildNodes returns a value indicating whether the calling node has children.

Syntax

Result = *Obj*->[\[IDLffXMLDOMNode::\]HasChildNodes\(\)](#)

Return Value

Returns 1 if the calling node has children, or 0 otherwise.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::Init

The `IDLffXMLDOMNode::Init` function method initializes the object, but this class should not be instantiated directly. Instead, methods such as [IDLffXMLDOMNode::GetFirstChild](#) are used to create objects of all classes except [IDLffXMLDOMDocument](#).

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNode::InsertBefore

The `IDLffXMLDOMNode::InsertBefore` function method inserts a new node into the calling node's children list at the location before a reference node.

If the reference node is not specified or is a null object reference, the new node is inserted at the end of the list of children.

If the new node is an [IDLffXMLDOMDocumentFragment](#), all of its children are inserted in the same order before the reference node.

If the new node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

Syntax

```
Result = Obj->[IDLffXMLDOMNode::]InsertBefore( NewChild [, RefChild] )
```

Return Value

Returns an object reference to the new child node.

Arguments

NewChild

An object reference to an instance of an `IDLffXMLDOMNode` subclass that refers to the node to insert.

RefChild

An object reference to an instance of an `IDLffXMLDOMNode` subclass that refers to the reference node. The new child node is inserted before the reference node. The reference node must be a child of the calling node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::RemoveChild

The `IDLffXMLDOMNode::RemoveChild` function method removes an existing child node from the calling node's child list.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

Syntax

```
Result = Obj->[IDLffXMLDOMNode::]RemoveChild( OldChild )
```

Return Value

Returns an object reference to the old child node.

Arguments

OldChild

An object reference to an instance of an `IDLffXMLDOMNode` subclass that refers to the node that is being removed. The old child node must be a child of the calling node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::ReplaceChild

The `IDLffXMLDOMNode::ReplaceChild` function method replaces an existing child node with a new child node into the calling node's child list.

If the new child node is an [IDLffXMLDOMDocumentFragment](#), the old child node is replaced by all the [IDLffXMLDOMDocumentFragment](#) children, which are inserted in the same order.

If the new child node is already in the tree, it is first removed.

The ownership of the IDL object to which the *NewChild* object reference refers is changed so that it is no longer owned by its previous owner and becomes owned by the calling object. Therefore, destroying the calling object destroys the new child as well.

The ownership of the IDL object to which the *OldChild* object reference refers is transferred from this calling object to the document object. The old child node has no parent after it is replaced. The document object becomes the new owner of the old child node, which is destroyed when the document object is destroyed.

Syntax

```
Result = Obj->[IDLffXMLDOMNode::]ReplaceChild( NewChild, OldChild )
```

Return Value

Returns an object reference to the old child node.

Arguments

NewChild

An object reference to an instance of an `IDLffXMLDOMNode` subclass that refers to the node to put into the tree, replacing the old child node.

OldChild

An object reference to an instance of an `IDLffXMLDOMNode` subclass that refers to the node that is being replaced. The old child node must be a child of the calling node.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNode::SetNodeValue

The IDLffXMLDOMNode::SetNodeValue procedure method sets the node's value to the contents of a string.

Note

This method is applicable only to the following node types: Attribute, Text, CDATA, Comment, and ProcessingInstruction. For all other node types, the method does nothing. For more information, see [“IDLffXMLDOMNode::GetNodeValue Return Values”](#) on page 3672.

Syntax

Obj->[IDLffXMLDOMNode:]SetNodeValue, *Node Value*

Arguments

NodeValue

A scalar string value used to set the node's value.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMNodeIterator

The `IDLffXMLDOMNodeIterator` class is used to navigate a DOM tree by creating a node object for accessing a DOM node and then destroying that node object as the iterator moves to another DOM node. The iterator creates an object and returns an object reference to that object each time the iterator moves, destroying the object that it last returned when the iterator last moved. This process lets the application visit the nodes in a DOM tree efficiently and easily.

The iterator moves back and forth through a document in a depth-first document-order traversal that corresponds to the order of the starting tags in an XML document. The node iterator is conceptually a “current” node pointer into the DOM tree. The pointer is positioned between nodes, so there is no concept of a current node. Instead, nodes on either side of the iterator's current position are referred to as the next and previous nodes. When the iterator moves, it returns either the next node or the previous node, depending on the direction it moves. The iterator is then positioned after the next node or before the previous node, again depending on the direction.

When the iterator is positioned at the start of a list of nodes, it has a next node, but no previous node. When the iterator is positioned at the end of a list of nodes, it has a previous node, but no next node.

The node specified when the iterator is created is the root node for the iterator. The iterator is positioned before the root node when the iterator is created. The nodes following the root node are the root node's children, if any. The iterator cannot move to siblings or to the parent of the root node. The root node therefore represents the top node of the subtree visible to the iterator.

The iterator never destroys the [IDLffXMLDOMDocument](#) objects that it might return. The iterator can only return an `IDLffXMLDOMDocument` object if an `IDLffXMLDOMDocument` object is the root node.

Objects of this class are created with the [IDLffXMLDOMDocument::CreateNodeIterator](#) method.

Superclasses

None

Creation

See [IDLffXMLDOMNodeIterator::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMNodeIterator::Cleanup](#)
- [IDLffXMLDOMNodeIterator::Init](#)
- [IDLffXMLDOMNodeIterator::NextNode](#)
- [IDLffXMLDOMNodeIterator::PreviousNode](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.2	Introduced
-----	------------

IDLffXLMDOMNodelerator Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMNodeIterator::Cleanup

The IDLffXMLDOMNodeIterator::Cleanup procedure method performs cleanup on the node-iterator object. As part of this cleanup, the method destroys any other objects that were created by the iterator object. In particular, the node object returned when the iterator was last moved is destroyed. The destruction of the iterator object does not affect any corresponding nodes in the DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMNodeIterator::Init

The `IDLffXMLDOMNodeIterator::Init` function method initializes the object, but this class should not be instantiated directly. Instead, use the [IDLffXMLDOMDocument::CreateNodeIterator](#) method to create instances of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMNodeIterator::NextNode

The `IDLffXMLDOMNodeIterator::NextNode` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that appears after the iterator's current position in document-order traversal. The iterator's current position is then updated to the position immediately after the node returned by this method.

This method destroys the object returned by the most recent previous invocation of [IDLffXMLDOMNodeIterator::NextNode](#) or [IDLffXMLDOMNodeIterator::PreviousNode](#).

Syntax

Result = *Obj*->[[IDLffXMLDOMNodeIterator::](#)]NextNode()

Return Value

Returns the object reference to the object that refers to the next node in the DOM tree.

If the iterator is positioned after the last node in the subtree under the iterator's root node, this method returns a null object reference, and the iterator's position does not change.

The first time this method is called after the iterator is created, the return value is the iterator's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMNodeIterator::PreviousNode

The `IDLffXMLDOMNodeIterator::PreviousNode` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that appears before the iterator's current position in document-order traversal. The iterator's current position is then updated to the position immediately before the node returned by this method.

This method destroys the object returned by the most recent previous invocation of [IDLffXMLDOMNodeIterator::NextNode](#) or [IDLffXMLDOMNodeIterator::PreviousNode](#).

Syntax

Result = *Obj*->[\[IDLffXMLDOMNodeIterator::\]PreviousNode\(\)](#)

Return Value

Returns the object reference to the object that refers to the previous node in the DOM tree.

If the iterator is positioned before the iterator's root node, this method returns a null object reference, and the iterator's position does not change. This is the situation immediately after an iterator's creation.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMText::IsIgnorableWhitespace

The IDLffXMLDOMText::IsIgnorableWhitespace function method indicates whether the text node contains ignorable whitespace.

In order for the parser to distinguish between ignorable and non-ignorable white space, validation must be performed during parsing with a DTD or schema.

Syntax

Result = *Obj*->[IDLffXMLDOMText::]IsIgnorableWhitespace()

Return Value

Returns 1 if the text node contains ignorable whitespace, or 0 if the text node contains whitespace that is not ignorable.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMText::SplitText

The IDLffXMLDOMText::SplitText function method breaks a text node into two nodes, splitting the text at the specified offset. Both nodes are kept in the same tree as siblings. The method both modifies its caller and creates an instance of a new IDLffXMLDOMText object, which contains the text following the offset point. When the offset is equal to the length of the string, the new node has no value data.

Syntax

Result = *Obj*->[IDLffXMLDOMText::]SplitText(*Offset*)

Return Value

Returns an object reference to the new IDLffXMLDOMText object.

Arguments

Offset

An integer containing the offset into the string at which to split it.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLffXMLDOMTreeWalker

The `IDLffXMLDOMTreeWalker` class is used to navigate a DOM tree by creating a node object for accessing a DOM node and then destroying that node object as the tree walker is moved to another DOM node. The walker creates an object and returns an object reference to that object each time the walker moves, destroying the object that it last returned when the walker last moved. This process lets the application visit the nodes in a DOM tree efficiently and easily.

The tree walker is conceptually a “current” node pointer into the DOM tree. When the walker moves, it returns an object reference to a newly created instance of a node that represents the DOM node where the walker is now positioned.

The node specified when the tree walker is created is the root node for the walker. The walker is positioned at the root node when the walker is created. The walker cannot move to an ancestor of the root node. The root node, its children, and all of its siblings and their children compose the subtree visible to the walker.

The tree walker never destroys the [IDLffXMLDOMDocument](#) objects that it might return. The walker can only return an [IDLffXMLDOMDocument](#) object if an [IDLffXMLDOMDocument](#) object is the root node.

Objects of this class are created with the [IDLffXMLDOMDocument::CreateTreeWalker](#) method.

Superclasses

None

Creation

See [IDLffXMLDOMTreeWalker::Init](#).

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLffXMLDOMTreeWalker::Cleanup](#)

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::Init](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)
- [IDLffXMLDOMTreeWalker::SetCurrentNode](#)

In addition, this class inherits the methods of any superclasses.

Version History

6.2	Introduced
-----	------------

IDLfXMLDOMTreeWalker Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

IDLffXMLDOMTreeWalker::Cleanup

The IDLffXMLDOMTreeWalker::Cleanup procedure method performs cleanup on the tree-walker object. As part of this cleanup, the method destroys any other objects that were created by the walker object. The destruction of the walker object does not affect any corresponding nodes in the DOM tree.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

Syntax

OBJ_DESTROY, *Obj*

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::FirstChild

The `IDLffXMLDOMTreeWalker::FirstChild` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that is the first child of the node to which the walker is currently pointing.

If the current node has no visible children, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

```
Result = Obj->[IDLffXMLDOMTreeWalker::]FirstChild()
```

Return Value

Returns an object reference to the first child of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible children.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::GetCurrentNode

The `IDLffXMLDOMTreeWalker::GetCurrentNode` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree to which the walker is currently pointing.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = *Obj*->[\[IDLffXMLDOMTreeWalker::\]GetCurrentNode\(\)](#)

Return Value

Returns the object reference to the object that refers to the tree walker's current position in the DOM tree.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::Init

The `IDLffXMLDOMTreeWalker::Init` function method initializes the object, but this class should not be instantiated directly. Instead, use the [IDLffXMLDOMDocument::CreateTreeWalker](#) method to create instances of this class.

This class should not be subclassed by a user class because the classes that create objects, such as [IDLffXMLDOMDocument](#), will not be aware of any user-defined classes.

IDLffXMLDOMTreeWalker::LastChild

The `IDLffXMLDOMTreeWalker::LastChild` function method creates an object that is a subclass of [IDLffXMLDOMNode](#) and returns the object reference to that object. The object refers to the node in the DOM tree that is the last child of the node to which the walker is currently pointing.

If the current node has no visible children, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = *Obj*->[[IDLffXMLDOMTreeWalker::](#)]LastChild()

Return Value

Returns an object reference to the last child of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible children.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::NextNode

The `IDLffXMLDOMTreeWalker::NextNode` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is visited next after the walker's current node in document-order traversal.

If the current node has no next node or the search for the next node looks above the tree walker's root node, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

```
Result = Obj->[IDLffXMLDOMTreeWalker::]NextNode()
```

Return Value

Returns an object reference to the next node in the DOM tree in the tree walker's document-order traversal, or a null object reference if the current node has no next node or the search for the next node looks above the walker's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::NextSibling

The `IDLffXMLDOMTreeWalker::NextSibling` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is the next sibling of the node to which the walker is currently pointing.

If the current node has no visible next sibling, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = *Obj*->[[IDLffXMLDOMTreeWalker::](#)]NextSibling()

Return Value

Returns an object reference to the next sibling of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible next sibling.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::ParentNode

The `IDLffXMLDOMTreeWalker::ParentNode` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is the parent of the node to which the walker is currently pointing.

If the search for a parent node attempts to look above the tree walker's root node or no visible ancestor node is found, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

```
Result = Obj->[IDLffXMLDOMTreeWalker:]ParentNode()
```

Return Value

Returns the object reference to the parent of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the search cannot find a visible ancestor node or attempts to look above the walker's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::PreviousNode

The `IDLffXMLDOMTreeWalker::PreviousNode` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is visited before the walker's current node in document-order traversal.

If the current node has no previous node or the search for the previous node looks above the tree walker's root node, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

```
Result = Obj->[IDLffXMLDOMTreeWalker::]PreviousNode()
```

Return Value

Returns an object reference to the previous node in the DOM tree in the tree walker's document-order traversal, or a null object reference if the current node has no previous node or the search for the previous node looks above the walker's root node.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::PreviousSibling

The `IDLffXMLDOMTreeWalker::PreviousSibling` function method creates an object that is a subclass of `IDLffXMLDOMNode` and returns the object reference to that object. The object refers to the node in the DOM tree that is the previous sibling of the node to which the walker is currently pointing.

If the current node has no visible previous sibling, this method returns a null object reference, and the current node does not change. Otherwise, the DOM tree node to which the returned object refers becomes the current node in the tree walker.

This method destroys the object returned by the most recent previous invocation of any of the following navigation methods:

- [IDLffXMLDOMTreeWalker::FirstChild](#)
- [IDLffXMLDOMTreeWalker::GetCurrentNode](#)
- [IDLffXMLDOMTreeWalker::LastChild](#)
- [IDLffXMLDOMTreeWalker::NextNode](#)
- [IDLffXMLDOMTreeWalker::NextSibling](#)
- [IDLffXMLDOMTreeWalker::ParentNode](#)
- [IDLffXMLDOMTreeWalker::PreviousNode](#)
- [IDLffXMLDOMTreeWalker::PreviousSibling](#)

A node object returned by this method is destroyed when the tree walker is destroyed.

Syntax

Result = *Obj*->[IDLffXMLDOMTreeWalker::]PreviousSibling()

Return Value

Returns an object reference to the previous sibling of the node in the DOM tree to which the tree walker is pointing, or a null object reference if the current node has no visible previous sibling.

Arguments

None

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLffXMLDOMTreeWalker::SetCurrentNode

The IDLffXMLDOMTreeWalker::SetCurrentNode procedure method sets the tree walker's current node to the specified node. You can use this method to position the walker at a particular node in the DOM tree.

Syntax

Obj->[IDLffXMLDOMTreeWalker::SetCurrentNode](#), *CurrentNode*

Arguments

CurrentNode

An object reference to an object belonging to a subclass of [IDLffXMLDOMNode](#).

For example:

```
oTop = oDocument->GetDocumentElement()
oWalker = oDocument->CreateTreeWalker( oTop )
oNode = oWalker->GetFirstChild()
oNode = oWalker->GetNextSibling()
; Move walker back to the top.
oWalker->SetCurrentNode, oTop
```

Keywords

None

Version History

-----	------------

IDLffXMLSAX

An IDLffXMLSAX object uses an XML SAX level 2 parser. The XML parser allows you to read an XML file and store arbitrary data from the file in IDL variables. The parser object's methods are *callbacks*. These methods are called automatically when the parser encounters different types of XML elements or attributes.

Note

To use the XML parser, you *must* write a subclass of this object class, overriding the object methods as necessary to process the data in a specific XML file or files. See [Chapter 20, “Using the XML Parser Object Class”](#) (*Application Programming*) for further information and examples.

The IDLffXMLSAX object encapsulates the Xerces validating XML parser; see <http://xml.apache.org> for details.

Note

For more information on XML, see [“About XML”](#) (Chapter 20, *Application Programming*).

Superclasses

None

Subclasses

You *must* write a subclass of this object, overriding object methods as necessary to retrieve information from the XML file.

Creation

See [“IDLffXMLSAX::Init”](#) on page 3765

Properties

Objects of this class have the following properties. See [“IDLffXMLSAX Properties”](#) on page 3742 for details on individual properties.

- [FILENAME](#)
- [NAMESPACE_PREFIXES](#)

- `PARSER_LOCATION`
- `PARSER_PUBLICID`
- `PARSER_URI`
- `SCHEMA_CHECKING`
- `VALIDATION_MODE`

Methods

This class has the following methods:

- `IDLffXMLSAX::AttributeDecl`
- `IDLffXMLSAX::Characters`
- `IDLffXMLSAX::Cleanup`
- `IDLffXMLSAX::Comment`
- `IDLffXMLSAX::ElementDecl`
- `IDLffXMLSAX::EndCDATA`
- `IDLffXMLSAX::EndDocument`
- `IDLffXMLSAX::EndDTD`
- `IDLffXMLSAX::EndElement`
- `IDLffXMLSAX::EndEntity`
- `IDLffXMLSAX::EndPrefixMapping`
- `IDLffXMLSAX::Error`
- `IDLffXMLSAX::ExternalEntityDecl`
- `IDLffXMLSAX::FatalError`
- `IDLffXMLSAX::GetProperty`
- `IDLffXMLSAX::IgnorableWhitespace`
- `IDLffXMLSAX::Init`
- `IDLffXMLSAX::InternalEntityDecl`
- `IDLffXMLSAX::NotationDecl`
- `IDLffXMLSAX::ParseFile`
- `IDLffXMLSAX::ProcessingInstruction`

- `IDLffXMLSAX::SetProperty`
- `IDLffXMLSAX::SkippedEntity`
- `IDLffXMLSAX::StartCDATA`
- `IDLffXMLSAX::StartDocument`
- `IDLffXMLSAX::StartDTD`
- `IDLffXMLSAX::StartElement`
- `IDLffXMLSAX::StartEntity`
- `IDLffXMLSAX::StartPrefixmapping`

IDLffXMLSAX Properties

IDLffXMLSAX objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLffXMLSAX::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLffXMLSAX::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLffXMLSAX::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [FILENAME](#)
- [NAMESPACE_PREFIXES](#)
- [PARSER_LOCATION](#)
- [PARSER_PUBLICID](#)
- [PARSER_URI](#)
- [SCHEMA_CHECKING](#)
- [VALIDATION_MODE](#)

FILENAME

A string containing the filename of the XML file being parsed.

Note

This property is only available during a parse operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

NAMESPACE_PREFIXES

A Boolean value indicating whether namespace prefixes are enabled. Namespace prefixes are enabled if this property is set to true. By default, namespace prefixes are disabled.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARSER_LOCATION

A two-element array containing the approximate location of the parser within the entity being parsed. The first element of the array is set to the line number and the second element is set to the column number.

Note

This property is only available during a parse operation.

Property Type	Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PARSER_PUBLICID

A string containing the Public ID for the entity being parsed, if it is available. If the Public ID is not available, an empty string is returned.

Note

This property is only available during a parse operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PARSER_URI

A string containing the base URI (System ID) for the entity being parsed, if it is available. If the value is available, it is always an absolute URI. If the System ID is not available, an empty string is returned.

Note

This property can be used to identify the document or external entity in diagnostics, or to resolve relative URIs. However, it is only available during a parse operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SCHEMA_CHECKING

An integer value to indicating the type of validation the parser should perform. XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation will occur. Possible values are:

0	No validation.
1	Validate only if a schema is provided. This is the default value.
2	Perform full schema constraint checking, if a schema is provided. This feature checks the schema grammar itself for additional errors. It does not affect the level of checking performed on document instances that use schema grammars.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VALIDATION_MODE

An integer value indicating the type of XML validation that the parser should perform. XML *Document Type Definitions* (DTDs) describe the structure and

allowed contents of an XML document. By default, the parser will validate the parsed XML file against the specified DTD, if one is provided; if no DTD specification is provided, no validation will occur. Possible values are:

0	No validation.
1	Validate only if a DTD is provided. This is the default value.
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLffXMLSAX::AttributeDecl

The IDLffXMLSAX::AttributeDecl procedure method is called when the parser detects an `<!ATTLIST . . . >` declaration in a DTD. This method is called once for each attribute declared by the tag.

Syntax

Obj->[IDLffXMLSAX::](#)AttributeDecl, *eName*, *aName*, *Type*, *Mode*, *Value*

Arguments

eName

A string containing the name of the element for which the attribute is being declared.

aName

A string containing the name of the attribute being declared.

Type

A string that specifying the type of attribute being defined. Possible values are:

- 'CDATA'
- 'ID'
- 'IDREF'
- 'IDREFS'
- 'NMTOKEN'
- 'NMTOKENS'
- 'ENTITY'
- 'ENTITIES'

or two types of enumerated values. Enumerated values are encoded with parenthesized strings such as `(a|b|c)` to indicate that strings `a`, `b`, or `c` are permissible. If the string is an enumeration of notation names, the string `"NOTATION "` (note the space after the second “N”) precedes the parenthesized string.

Mode

A string specifying restrictions on the value of the attribute. Possible values are:

- '#IMPLIED' - the application determines the value
- '#REQUIRED' - the value must be given; defaulting is not permitted
- '#FIXED' - only one value is permitted
- "" - a null string (the value specified by the *Value* argument is used as the default)

Value

A string containing the default value for the attribute. If *Value* contains a null string, no default value was specified.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::Characters

The IDLffXMLSAX::Characters procedure method is called when the parser detects text in the parsed document.

Syntax

Obj->[IDLffXMLSAX::]Characters, *Chars*

Arguments

Chars

A string containing the text detected by the parser.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::Cleanup

The IDLffXMLSAX::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLffXMLSAX::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::Comment

The IDLffXMLSAX::Comment procedure method is called when the parser detects a comment section of the form `<!-- . . . -->`.

Syntax

Obj->[IDLffXMLSAX::](#)Comment, *Comment*

Arguments

Comment

A string containing the text within the detected comment section, without the delimiting characters (“<!--” and “-->”).

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::ElementDecl

The IDLffXMLSAX::ElementDecl procedure method is called when the parser detects an `<!ELEMENT . . . >` declaration in the DTD.

Syntax

Obj->[IDLffXMLSAX::](#)ElementDecl, *Name*, *Model*

Arguments

Name

A string containing the name of the element.

Model

A string containing the *content model* (sometimes called the *content specification*) for the element, with all whitespace removed.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::EndCDATA

The IDLffXMLSAX::EndCDATA procedure method is called when the parser detects the end of a `<![CDATA[. . .]>` text section.

Syntax

Obj->[IDLffXMLSAX::](#)EndCDATA

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::EndDocument

The IDLffXMLSAX::EndDocument procedure method is called when the parser detects the end of the XML document.

Syntax

Obj->[\[IDLffXMLSAX::\]](#)EndDocument

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::EndDTD

The IDLffXMLSAX::EndDTD procedure method is called when the parser detects the end of a Document Type Definition (DTD).

Syntax

Obj->[IDLffXMLSAX::](#)EndDTD

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::EndElement

The IDLffXMLSAX::EndElement procedure method is called when the parser detects the end of an element.

Syntax

Obj->[IDLffXMLSAX::]EndElement, *URI*, *Local*, *qName*

Arguments

URI

A string containing the namespace URI with which the element is associated, if any.

Note

A URI (or Uniform Resource Identifier) refers to the generic set of all names and addresses which are short strings which refer to objects.

Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A string containing the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::EndEntity

The IDLffXMLSAX::EndEntity procedure method is called when the parser detects the end of an internal or external entity expansion.

Syntax

Obj->[IDLffXMLSAX::]EndEntity, *Name*

Arguments

Name

A string containing the name of the entity.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::EndPrefixMapping

The IDLffXMLSAX::EndPrefixMapping procedure method is called when a previously declared prefix mapping goes out of scope.

Syntax

Obj->[IDLffXMLSAX::]EndPrefixMapping, *Prefix*

Arguments

Prefix

A string containing the namespace prefix that is going out of scope.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::Error

The IDLffXMLSAX::Error procedure method is called when the parser detects an error that is not expected to be fatal. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

For example, a violation of XML validity constraints is generally a non-fatal error.

Note

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj->[IDLffXMLSAX::]Error, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

Arguments

SystemID

A string containing the URI of the associated text.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message sent to the IDL output log.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::ExternalEntityDecl

The IDLffXMLSAX::ExternalEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declarations in the DTD for a parsed external entity.

Syntax

Obj->[IDLffXMLSAX::]ExternalEntityDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the entity name.

PublicID

A string containing the Public ID for the entity.

Note

If this value is not specified in the entity declaration, this variable will contain an empty string.

SystemID

A string containing the System ID for the entity, provided as an absolute URI.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::FatalError

The IDLffXMLSAX::FatalError procedure method is called when the parser detects a fatal error. When called, parsing will normally stop, but may sometimes continue long enough to report further errors. This method prints an IDL error string to the IDL output log.

Syntax

Obj->[IDLffXMLSAX::]FatalError, *SystemID*, *LineNumber*, *ColumnNumber*,
Message

Arguments

SystemID

A string containing the URI of the associated text.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message sent to the IDL output log.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::GetProperty

The IDLffXMLSAX::GetProperty procedure method is used to get the values of various properties of the parser.

Syntax

Obj->[IDLffXMLSAX::](#)GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLffXMLSAX Properties](#)” on page 3742 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::IgnorableWhitespace

The IDLffXMLSAX::IgnorableWhitespace procedure method is called when the parser detects whitespace that separates elements in an element content model.

Syntax

Obj->[IDLffXMLSAX::]IgnorableWhitespace, *Chars*

Arguments

Chars

A string containing the whitespace detected by the parser. Whitespace can consist of spaces, tabs, or newline characters in any combination.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::Init

The IDLffXMLSAX::Init function method initializes an XML parser object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. In most cases, you cannot call the Init method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLffXMLSAX' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLffXMLSAX::]Init([, *PROPERTY=value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLffXMLSAX Properties” on page 3742 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::InternalEntityDecl

The IDLffXMLSAX::InternalEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declaration in a DTD for (parsed) internal entities. The entity can be either a general entity or a parameter entity.

Syntax

Obj->[\[IDLffXMLSAX::\]](#)InternalEntityDecl, *Name*, *Value*

Arguments

Name

A string containing the entity name. Names that start with the “%” character are parameter entities; all others are general entities.

Value

A string containing the entity value. The entity value can contain arbitrary XML content, which will be reparsed when the entity is expanded.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::NotationDecl

The IDLffXMLSAX::NotationDecl procedure method is called when the parser detects a `<!NOTATION . . . >` declaration in a DTD.

Syntax

Obj->[IDLffXMLSAX::](#)NotationDecl, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the notation name.

PublicID

A string containing the Public ID for the notation.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

SystemID

A string containing the System ID for the notation, provided as an absolute URI.

Note

If this value is not specified in the notation declaration, this variable will contain an empty string.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::ParseFile

The IDLffXMLSAX::ParseFile procedure method parses the specified XML file. During the parsing operation, different object methods are called as different items within the XML file are detected. When this method returns, the parse operation is complete.

Syntax

Obj->[IDLffXMLSAX::]ParseFile, *Input* [, /URL] [, /XML_STRING]

Arguments

Input

A string containing the full path name of the file to be parsed. If the XML_STRING keyword is set, *Input* should be a string containing the XML data to be parsed. If the URL keyword is set, *Input* should be a Uniform Resource Locator.

Keywords

URL

Set this keyword to indicate that *Input* is a Uniform Resource Locator containing the XML data to be parsed rather than the name of an XML file.

XML_STRING

Set this keyword to indicate that *Input* is a string array containing XML data to be parsed rather than the name of an XML file.

Version History

5.6	Introduced
6.4	Added URL and XML_STRING keywords

IDLffXMLSAX::ProcessingInstruction

The IDLffXMLSAX::ProcessingInstruction procedure method is called when the parser detects a processing instruction.

Syntax

Obj->[IDLffXMLSAX::]ProcessingInstruction, *Target*, *Data*

Arguments

Target

A string specifying the target, which is the application that should process the instruction.

Data

A string specifying the data to be passed to the application specified by *Target*.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX:: SetProperty

The IDLffXMLSAX::SetProperty procedure method is used to set the values of various properties of the parser.

Syntax

Obj->[IDLffXMLSAX::]SetProperty [, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “IDLffXMLSAX Properties” on page 3742 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::SkippedEntity

The IDLffXMLSAX::SkippedEntity procedure method is called when the parser skips an entity and validation is not being performed. This method is rarely called by SAX parsers.

Syntax

Obj->[IDLffXMLSAX::]SkippedEntity, *Name*

Arguments

Name

A string containing the name of the entity that was skipped.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StartCDATA

The IDLffXMLSAX::StartCDATA procedure method is called when the parser detects the beginning of a `<![CDATA[. . .]>` text section.

Syntax

Obj->[IDLffXMLSAX::StartCDATA](#)

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StartDocument

The IDLffXMLSAX::StartDocument procedure method is called when the parser begins processing a document, and before any data is processed.

Syntax

Obj->[IDLffXMLSAX::](#)StartDocument

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StartDTD

The IDLffXMLSAX::StartDTD procedure method is called when the parser detects the beginning of a Document Type Definition (DTD).

Syntax

Obj->[IDLffXMLSAX::]StartDTD, *Name*, *PublicID*, *SystemID*

Arguments

Name

A string containing the declared name of the root element for the document.

PublicID

A string containing the *normalized* version of the Public ID (a URI) declared for the external subset, or an empty string if no external subset was declared. *Normalization* involves removal of unnecessary “.” and “. .” segments from the URI.

SystemID

A string containing the System ID (a URI) of the external subset, or an empty string if no external subset was declared.

Note

This URI has not been resolved into an absolute URI.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StartElement

The IDLffXMLSAX::StartElement procedure method is called when the parser detects the beginning of an element.

Syntax

Obj->[IDLffXMLSAX::]StartElement, *URI*, *Local*, *qName* [, *attrName*, *attrValue*]

Arguments

URI

A string containing the namespace URI with which the element is associated, if any.

Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

qName

A string containing the element name found in the XML file.

Note

If the element is associated with a namespace URI, this variable may contain an empty string.

attrName

A string array representing the names of the attributes associated with the element, if any.

attrValue

A string array representing the values of each attribute associated with the element, if any. The returned array will have the same number of elements as the array returned in the *attrName* keyword variable.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StartEntity

The IDLffXMLSAX::StartEntity procedure method is called when the parser detects the start of an internal or external entity expansion.

Syntax

Obj->[IDLffXMLSAX::](#)StartEntity, *Name*

Arguments

Name

A string containing the name of the entity.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StartPrefixmapping

The IDLffXMLSAX::StartPrefixMapping procedure method is called when the parser detects the beginning of a namespace declaration.

Syntax

Obj->[IDLffXMLSAX::]StartPrefixmapping, *Prefix*, *URI*

Arguments

Prefix

A string containing the prefix, which is being mapped. If the variable specified by *Prefix* contains an empty string, the mapping is for the default element namespace.

URI

A string containing the URI of the prefix namespace.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::StopParsing

Call the IDLffXMLSAX::StopParsing procedure method during a parse operation to halt the operation and cause the ParseFile method to return. This may be useful when parsing large XML files and the desired information is known to have been returned.

Syntax

Obj->[IDLffXMLSAX::]StopParsing

Arguments

None

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::UnparsedEntityDecl

The IDLffXMLSAX::UnparsedEntityDecl procedure method is called when the parser detects an `<!ENTITY . . . >` declaration that includes the `NDATA` keyword, indicating that the entity is not meant to be parsed. The value of the `NDATA` keyword generally specifies the name of a *notation*, which in turn specifies the type of data.

Syntax

Obj->[IDLffXMLSAX::]UnparsedEntityDecl, *Name*, *PublicID*, *SystemID*, *Notation*

Arguments

Name

A string containing the name of the unparsed entity.

PublicID

A string containing the Public ID of the notation specified by the entity's `NDATA` keyword, or an empty string if no Public ID was declared.

SystemID

A string containing the System ID of the notation specified by the entity's `NDATA` keyword. This value is normally an absolute URI.

Notation

A string containing the name of the notation specified by the entity's `NDATA` keyword.

Keywords

None

Version History

5.6	Introduced
-----	------------

IDLffXMLSAX::Warning

The IDLffXMLSAX::Warning procedure method is called when the parser detects a problem during processing. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

Note

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

Syntax

Obj->[IDLffXMLSAX::](#)Warning, *SystemID*, *LineNumber*, *ColumnNumber*,
Message

Arguments

SystemID

A string containing the URI of the text that generated the error.

LineNumber

A longword integer representing the line number that contains the error.

ColumnNumber

A longword integer representing the column number that contains the error.

Message

A string containing the error message.

Keywords

None

Chapter 31

Graphics Object Classes

This chapter describes IDL's built-in graphics class library.

IDLgrAxis	3787	IDLgrPolygon	4175
IDLgrBuffer	3823	IDLgrPolyline	4218
IDLgrClipboard	3859	IDLgrPrinter	4251
IDLgrColorbar	3893	IDLgrROI	4282
IDLgrContour	3915	IDLgrROIGroup	4303
IDLgrFilterChain	3957	IDLgrScene	4322
IDLgrFont	3965	IDLgrShader	4335
IDLgrImage	3975	IDLgrShaderBytscl	4353
IDLgrLegend	4027	IDLgrShaderConvolve3	4364
IDLgrLight	4049	IDLgrSurface	4375
IDLgrModel	4068	IDLgrSymbol	4423
IDLgrMPEG	4094	IDLgrTessellator	4435
IDLgrPalette	4111	IDLgrText	4447
IDLgrPattern	4133	IDLgrTextEdit	4482
IDLgrPlot	4144	IDLgrView	4497

IDLgrViewgroup	4516
IDLgrVolume	4528
IDLgrVRML	4561
IDLgrWindow	4583

IDLgrAxis

An axis object represents a single vector that may include a set of tick marks, tick labels, and a title.

An IDLgrAxis object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrAxis::Init](#)” on page 3820.

Properties

Objects of this class have the following properties. See “[IDLgrAxis Properties](#)” on page 3790 for details on individual properties.

- [ALL](#)
- [AM_PM](#)
- [COLOR](#)
- [DAYS_OF_WEEK](#)
- [DEPTH_TEST_FUNCTION](#)
- [DIRECTION](#)
- [EXTEND](#)
- [HIDE](#)
- [LOG](#)
- [MINOR](#)
- [NOTEXT](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [ALPHA_CHANNEL](#)
- [CLIP_PLANES](#)
- [CRANGE](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [EXACT](#)
- [GRIDSTYLE](#)
- [LOCATION](#)
- [MAJOR](#)
- [MONTHS](#)
- [PALETTE](#)
- [RANGE](#)
- [SHADER](#)

- SUBTICKLEN
- TEXTBASELINE
- TEXTUPDIR
- TICKDIR
- TICKFRMTDATA
- TICKLAYOUT
- TICKTEXT
- TICKVALUES
- USE_TEXT_COLOR
- XRANGE
- YRANGE
- ZRANGE
- TEXTALIGNMENTS
- TEXTPOS
- THICK
- TICKFORMAT
- TICKINTERVAL
- TICKLEN
- TICKUNITS
- TITLE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrAxis::Cleanup](#)
- [IDLgrAxis::GetCTM](#)
- [IDLgrAxis::GetProperty](#)
- [IDLgrAxis::Init](#)
- [IDLgrAxis::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property

6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property

IDLgrAxis Properties

IDLgrAxis objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrAxis::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrAxis::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrAxis::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [AM_PM](#)
- [COLOR](#)
- [DAYS_OF_WEEK](#)
- [DEPTH_TEST_FUNCTION](#)
- [DIRECTION](#)
- [EXTEND](#)
- [HIDE](#)
- [LOG](#)
- [MINOR](#)
- [NOTEXT](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SUBTICKLEN](#)
- [TEXTBASELINE](#)
- [TEXTUPDIR](#)
- [TICKDIR](#)
- [TICKFRMTDATA](#)
- [ALPHA_CHANNEL](#)
- [CLIP_PLANES](#)
- [CRANGE](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [EXACT](#)
- [GRIDSTYLE](#)
- [LOCATION](#)
- [MAJOR](#)
- [MONTHS](#)
- [PALETTE](#)
- [RANGE](#)
- [SHADER](#)
- [TEXTALIGNMENTS](#)
- [TEXTPOS](#)
- [THICK](#)
- [TICKFORMAT](#)
- [TICKINTERVAL](#)

- [TICKLAYOUT](#)
- [TICKTEXT](#)
- [TICKVALUES](#)
- [USE_TEXT_COLOR](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)
- [TICKLEN](#)
- [TICKUNITS](#)
- [TITLE](#)
- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the entire axis, including tick text and title text. The default value of 1.0 causes IDL to draw the axis completely opaque. If the value of this property is less than 1.0, then the pixels of the axis are blended with the pixels already on the screen, where the color of the axis is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color mode. When the `USE_TEXT_COLOR` property is set to a non-zero value, the tick and title text is drawn using the value of the `ALPHA_CHANNEL` property from the

tick and/or title text objects. In other words, USE_TEXT_COLOR also implies using the text objects' alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AM_PM

A string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CLIP_PLANES

A 4 by n floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this axis. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0, 0, 0].

Property Type	Color		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CRANGE

A double-precision floating-point vector of the form [*minval, maxval*] that will contain the actual full range of the axis. This computed range may not exactly match the requested range provided via the `RANGE` property due to tick mark rounding and effects of the `EXTEND` property.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DAYS_OF_WEEK

A string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

0	Inherit the value set by the parent model or view (the default). The parent view always enables depth testing. A model may also enable or disable depth testing.
1	Explicitly disable depth buffer testing while drawing this object.
2	Explicitly enable depth testing for this object

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always

sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

0	INHERIT	Use value from parent model or view
1	NEVER	Never passes
2	LESS	Passes if the object's depth is less than the depth buffer's value
3	EQUAL	Passes if the object's depth is equal to the depth buffer's value
4	LESS OR EQUAL	Passes if the object's depth is less than or equal to the depth buffer's value
5	GREATER	Passes if the object's depth is greater than or equal to the depth buffer's value
6	NOT EQUAL	Passes if the object's depth is not equal to the depth buffer's value
7	GREATER OR EQUAL	Passes if the object's depth is greater than or equal to the depth buffer's value
8	ALWAYS	Always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled:

0	Inherit the value set by the parent model or view (the default). The parent view always enables depth writing. A model may also enable or disable depth writing.
1	Explicitly disable depth buffer writing while rendering this object.
2	Explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIRECTION

An integer value that specifies which axis is being created:

0	Create X axis
1	Create Y axis
2	Create Z axis

Specifying this property is the same as specifying the optional *Direction* argument to the [IDLgrAxis::Init](#) method.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EXACT

A Boolean value that determines whether to force the axis range to be exactly as specified. If this property is not set, the range may be lengthened or shortened slightly to allow for evenly spaced tick marks.

Property Type	Boolean		
Name String	Use exact axis range		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EXTEND

A Boolean value that determines whether to extend the axis slightly beyond the range of data to be plotted, which is a value specified by the RANGE property. This can be useful when you specify the axis range based on the minimum and maximum data values, but do not want the graphic to extend all the way to the end of the axis. The amount by which the axis is extended is determined by the system using a number of factors, including the MAJOR property of the axis.

Property Type	Boolean		
Name String	Extend axis		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GRIDSTYLE

An integer or two-element vector that indicates the line style that should be used to draw the axis' tick marks. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `GRIDSTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as a Linestyle drop-down list, with the following options:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn. Options:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATION

A two- or three-element floating-point vector of the form $[x, y]$ or $[x, y, z]$ to specify the coordinate through which the axis should pass. The default is $[0, 0, 0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LOG

A Boolean value that indicates whether the axis is logarithmic.

Property Type	Boolean		
Name String	Use logarithmic axis		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MAJOR

An integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

Property Type	Integer		
Name String	Number of major ticks		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

Property Type	Integer		
Name String	Number of minor ticks		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MONTHS

A string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the TICKFORMAT property.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NOTEXT

A Boolean value or an enumerated list item indicating whether the tick labels and the axis title should be drawn.

Value	Property Sheet Value	Description
0	True	Draw tick labels and axis title (the default)
1	False	Do not draw tick labels and axis title

Property Type	ENUMLIST		
Name String	Text show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

The object reference of a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrAxis object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: No	Init: No	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RANGE

A two-element floating-point vector containing the minimum and maximum data values covered by the axis. The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the axis is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single

IDLgrShader object may be associated with additional axis objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

Property Type	FLOAT		
Name String	Minor tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTALIGNMENTS

A two-element floating-point vector, [*horizontal*, *vertical*], specifying the horizontal and vertical alignments for the tick text. Each alignment value should be a value between 0.0 and 1.0. For horizontal alignment, 0.0 left-justifies the text; 1.0 right-justifies the text. For vertical alignment, 0.0 bottom-justifies the text, 1.0 top-justifies the text.

The defaults are as follows:

- X-Axis: [0.5, 1.0] (centered horizontally, top-justified vertically)
- Y-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)
- Z-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)

Set this property to a scalar value to *restore* the default values after they have been explicitly set.

Property Type	Floating-point scalar or vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTBASELINE

A two- or three-element floating-point vector describing the direction in which the baseline of the tick text is to be oriented. Use this property in conjunction with the TEXTUPDIR property to specify the plane on which the tick text lies. The default is [1,0,0].

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTPOS

An integer that indicates on which side of the axis to draw the tick text labels. The table below describes the placement of the tick text with each setting.

Axis	TEXTPOS = 0	TEXTPOS = 1
X	Tick text will be drawn <i>below</i> the X axis, where <i>below</i> is defined as being toward the direction of the negative Y axis (this is the default).	Tick text will be drawn <i>above</i> the X axis, where <i>above</i> is described as being toward the direction of the positive Y axis.
Y	Tick text will be drawn to the <i>left</i> of the Y Axis, where <i>left</i> is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the <i>right</i> of the Y axis, where <i>right</i> is defined as being toward the direction of the positive X axis.
Z	Tick text will be drawn to the <i>left</i> of the Z axis, where <i>left</i> is defined as being toward the direction of the negative X axis (this is the default).	Tick text will be drawn to the <i>right</i> of the Z axis, where <i>right</i> is defined as being toward the direction of the positive X axis.

Table 31-1: Values for the TEXTPOS property

In a property sheet, this property appears as an enumerated list. Options:

- Below/left: Text will be drawn below the axis and to the left.
- Above/right: Text will be drawn above the axis and to the right.

Property Type	ENUMLIST		
Name String	Text position		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTUPDIR

A two- or three-element floating-point vector describing the direction in which the up-vector of the tick text is to be oriented. Use this property in conjunction with the TEXTBASELINE property to specify the plane on which the tick text lies.

TEXTUPDIR should be orthogonal to TEXTBASELINE. The default is as follows:

- X-Axis: [0, 1, 0]
- Y-Axis: [0, 1, 0]
- Z-Axis: [0, 0, 1]

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value in points between 1.0 and 10.0 that specifies the line thickness used to draw the axis. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as a Thickness drop-down list with the following options:

Property Type	Thickness		
Name String	Line thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKDIR

An integer value of zero or one to indicate the tick mark direction.

Axis	TICKDIR = 0	TICKDIR = 1
X	Tick marks will be drawn above the X axis, in the direction of the positive Y axis (this is the default).	Tick marks will be drawn below the X axis.
Y	Tick marks will be drawn to the right of the Y axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Y axis.
Z	Tick marks will be drawn to the right the Z axis, in the direction of the positive X axis (this is the default).	Tick marks will be drawn to the left of the Z axis.

Table 31-2: Tick Mark Direction Values

In a property sheet, this property appears as an enumerated list, with the following options:

- Right/above: Tick marks will be drawn above the axis and to the right.
- Left/below: Tick marks will be drawn below the axis and to the left.

Property Type	ENUMLIST		
Name String	Tick direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKFORMAT

A string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. (The [TICKUNITS](#) property determines the number of levels for an axis.) If the number of strings stored in this property is one, `GetProperty` returns a scalar string, otherwise `GetProperty` returns an array of strings.

If the string begins with an open parenthesis, it is treated as a standard format string. (See “[Format Codes](#)” (Chapter 18, *Application Programming*).)

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [TICKUNITS](#) is specified.

If [TICKUNITS](#) are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

If [TICKUNITS](#) are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Whether or not [TICKUNITS](#) is specified, the callback function can also define a `DATA` keyword. If the callback function accepts the `DATA` keyword, it will be set equal to the value (if any) of the [TICKFRMTDATA](#) property.

Note

For more information, see “[XYZ]TICKFORMAT” on page 5630.

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

Property Type	String or string array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKFRMTDATA

A value of any type that will be passed to the user-supplied formatting callback function (specified via the TICKFORMAT property) as the value of the DATA keyword. By default, this value is undefined, indicating that the value of the DATA keyword will be undefined.

Note

TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrAxis::GetProperty method.

Property Type	Scalar of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKINTERVAL

A floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis RANGE and the number of major tick marks (MAJOR). This property takes precedence over MAJOR.

For example, if TICKUNITS=['S','H','D'], and TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

Property Type	FLOAT		
Name String	Tick interval		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLAYOUT

An integer scalar or enumerated list item that indicates the tick layout style to be used to draw each level of the axis. Valid values include:

Value	Property Sheet Value	Description
0	Axis plus labels	The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
1	Labels only	Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
2	Box style	Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

Property Type	ENUMLIST		
Name String	Tick layout		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Major tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKTEXT

An object reference to a single instance of the [IDLgrText](#) object class (with multiple strings) or a vector of instances of the [IDLgrText](#) object class (one per major tick) to specify the annotations to be assigned to the tickmarks. By default, with `TICKTEXT` set equal to a null object, IDL computes the tick labels based on major tick values. The positions of the provided text objects may be overwritten; position is determined according to tick mark location. The tickmark text will have the same color as the [IDLgrAxis](#) object, regardless of the color specified by the `COLOR` property of the [IDLgrText](#) object or objects, unless the `USE_TEXT_COLOR` property is specified.

Note

If IDL computes the tick labels, the text object it creates will be destroyed automatically when the axis object is destroyed, even if you have altered the properties of the text object. If you create your own text object containing tickmark text, however, it will *not* be destroyed automatically.

Property Type	Object reference or string vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKUNITS

A string (or a vector of strings) indicating the units to be used for axis tick labeling. If the number of levels in the axis is one, `GetProperty` returns a scalar string, otherwise `GetProperty` returns an array of strings.

If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "" - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000 A.D., respectively.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	STRING		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKVALUES

A floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis

range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TITLE

An object reference to an instance of the [IDLgrText](#) object class that specifies the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location. The title will have the same color as the [IDLgrAxis](#) object, regardless of the color specified by the [COLOR](#) property of the [IDLgrText](#) object, unless the [USE_TEXT_COLOR](#) property is specified.

Note

Objects specified via this property are not automatically cleaned up when the [IDLgrAxis](#) object is destroyed.

The [IDLgrText](#) object becomes a child of the [IDLgrAxis](#) object; therefore, to use the same [IDLgrText](#) object for multiple axes, you must use multiple [IDLgrAxis](#) objects.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USE_TEXT_COLOR

A Boolean value that indicates whether, for the tick text and/or title of the axis, the color property values set for the given [IDLgrText](#) objects are to be used to draw those text items. By default, this value is zero, indicating that the color properties of the [IDLgrText](#) objects will be ignored, and that the [COLOR](#) property for the axis object will be used for these text items instead.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of y data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrAxis::Cleanup

The IDLgrAxis::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrAxis::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrAxis::GetCTM

The IDLgrAxis::GetCTM function method returns the graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrAxis::]GetCTM([, DESTINATION=objref] [, PATH=objref(s)]  
[, TOP=objref])
```

Return Value

Returns the 4 x 4 double-precision floating-point graphics transform matrix.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the axis object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrAxis::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrAxis::GetProperty

The IDLgrAxis::GetProperty procedure method retrieves the value of a property or group of properties for the axis.

Syntax

Obj->[IDLgrAxis::]GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrAxis Properties” on page 3790 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.0	Introduced
-----	------------

IDLgrAxis::Init

The IDLgrAxis::Init function method initializes an axis object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrAxis' [, Direction] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrAxis::]Init([Direction] [, PROPERTY=value])    (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Direction

An integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis.

Note

The value specified by the *Direction* argument is used to initialize the value of the **DIRECTION** property of the IDLgrAxis object.

Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3790 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrAxis:: SetProperty

The IDLgrAxis::SetProperty procedure method sets the value of a property or group of properties for the axis.

Syntax

Obj->[IDLgrAxis::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrAxis Properties](#)” on page 3790 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrBuffer

An IDLgrBuffer object is an in-memory, off-screen destination object. Object trees can be drawn to instances of the IDLgrBuffer object and the resulting image can be retrieved from the buffer using the Read() method. The off-screen representation avoids dithering artifacts by providing a full-resolution buffer for objects using either the RGB or Color Index color models.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrBuffer::Init](#)” on page 3845.

Properties

Objects of this class have the following properties. See “[IDLgrBuffer Properties](#)” on page 3825 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [IMAGE_DATA](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)

- [UNITS](#)
- [ZBUFFER_DATA](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrBuffer::Cleanup](#)
- [IDLgrBuffer::Draw](#)
- [IDLgrBuffer::Erase](#)
- [IDLgrBuffer::GetContiguousPixels](#)
- [IDLgrBuffer::GetDeviceInfo](#)
- [IDLgrBuffer::GetFontnames](#)
- [IDLgrBuffer::GetProperty](#)
- [IDLgrBuffer::GetTextDimensions](#)
- [IDLgrBuffer::Init](#)
- [IDLgrBuffer::PickData](#)
- [IDLgrBuffer::QueryRequiredTiles](#)
- [IDLgrBuffer::Read](#)
- [IDLgrBuffer::Select](#)
- [IDLgrBuffer::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.2	Added QueryRequiredTiles method

IDLgrBuffer Properties

IDLgrBuffer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrBuffer::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrBuffer::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrBuffer::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [IMAGE_DATA](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)
- [ZBUFFER_DATA](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object (except IMAGE_DATA and ZBUFFER_DATA).

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

A Boolean value or enumerated list item that determines the color model to be used for the buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color Index

Note

See [“Color and Destination Objects”](#) (*Object Programming*) for more information.

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the dimensions of the buffer in units specified by the UNITS property. The default is [640,480].

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMAGE_DATA

A byte array representing the image that is currently rendered within the buffer. If the buffer uses an RGB color model, the returned array will have dimensions (3, *xdim*, *ydim*). If the window object uses an indexed color model, the returned array will have dimensions (*xdim*, *ydim*).

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

N_COLORS

An integer that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values to be loaded into the buffer's color lookup table.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrBuffer object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer value or enumerated list item that indicates the rendering quality with which graphics are to be drawn to the buffer. Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A two-element floating-point vector of the form $[xres, yres]$ that specifies the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: $[0.035277778, 0.035277778]$ (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form $[width, height]$ that specifies the maximum allowed dimensions (measured in device units) for the buffer object.

Note

The maximum buffer dimension size is always 4096 by 4096.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to 1600 x 1200

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrBuffer::Cleanup

The IDLgrBuffer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrBuffer::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::Draw

The IDLgrBuffer::Draw procedure method draws the given picture to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

```
Obj->[IDLgrBuffer::]Draw [, Picture] [, CREATE_INSTANCE={1 | 2}]  
[, DRAW_INSTANCE={1 | 2}]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object) or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that the instance, or unchanging part of the drawing, is drawn to the device first. IDL then draws the changing part of the drawing, indicated by the scene, view or viewgroup specified by the Picture argument.

If the value of this keyword is 1, IDL copies both the instance image (color buffer) and the instance depth buffer to the device.

If the value of this keyword is 2, IDL copies only the instance image to the device.

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::Erase

The IDLgrBuffer::Erase procedure method erases this graphics destination.

Syntax

Obj->[IDLgrBuffer::]Erase [, COLOR=*index or RGB vector*]

Arguments

None

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*].

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::GetContiguousPixels

The `IDLgrBuffer::GetContiguousPixels` function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the `N_COLORS` property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the `SHADE_RANGE` property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

Syntax

Result = *Obj*->[IDLgrBuffer::]GetContiguousPixels()

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::GetDeviceInfo

The IDLgrBuffer::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrBuffer::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [, MAX_TILE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two-element integer array that specifies the maximum texture size supported by the device.

MAX_TILE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TILE_DIMENSIONS contains a two element integer array that specifies the maximum tile size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two-element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

5.0	Introduced
5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

IDLgrBuffer::GetFontnames

The IDLgrBuffer::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned. See [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrBuffer::]GetFontnames( FamilyName[, IDL_FONTS={0 | 1 | 2  
}] [, STYLES=string ] )
```

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, '', only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::GetProperty

The IDLgrBuffer::GetProperty procedure method retrieves the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrBuffer::]GetProperty[, *PROPERTY=variable*]

Keywords

Any property listed under “[IDLgrBuffer Properties](#)” on page 3825 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::GetTextDimensions

The `IDLgrBuffer::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the `IDLgrText RECOMPUTE_DIMENSIONS` property.

Syntax

```
Result = Obj->[IDLgrBuffer::]GetTextDimensions( TextObj [, DESCENT=variable]  
[, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a text or axis object that will be rendered in a window.

Arguments

TextObj

The object reference to a text or axis object for which text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values represent the distance to travel (parallel to the `UPDIR` vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if `TextObj` is an `IDLgrText` object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrBuffer::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::Init

The IDLgrBuffer::Init function method initializes the buffer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrBuffer' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrBuffer::]Init( [, PROPERTY=value)  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrBuffer Properties” on page 3825 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::PickData

The IDLgrBuffer::PickData function method maps a point in the two-dimensional device space of the buffer to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Warning

If you use the DEPTH_WRITE_DISABLE or DEPTH_TEST_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn, this also prevents the object from affecting the result returned by the PickData method (the return value will be 0). The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData.

Syntax

```
Result = Obj->[IDLgrBuffer::]PickData( View, Object, Location, XYZLocation  
[, DIMENSIONS=[width,height]][, PATH=objref(s)]  
[, PICK_STATUS=variable])
```

Return Value

Returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Note

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

Location

A two-element vector $[x, y]$ specifying the location in the buffer's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the `LOCATION` or `DIMENSIONS` properties (this is only possible with `IDLgrAxis`, `IDLgrImage`, and `IDLgrText` objects), these transformations will *not* be included in the data coordinates returned by the `PickData` function. This means that you may need to re-apply the transformation accomplished by specifying `LOCATION` or `DIMENSIONS` once you have retrieved the data coordinates with `PickData`. This situation does not occur if you transform the axis, text, or image object using the `[XYZ]COORD_CONV` properties.

Keywords**DIMENSIONS**

Set this keyword to a two-element array $[w, h]$ to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates $[x, y]$ specified in the *Location* argument, and will occupy the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions $[3, w, h]$.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 31-3: PICK_STATUS Keyword Values

Version History

5.0	Introduced
5.6	Added PICK_STATUS keyword

IDLgrBuffer::QueryRequiredTiles

The IDLgrBuffer::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

Note

If the device is in Color Index mode (COLOR_MODEL=1) or the image has [RENDER_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

Syntax

```
Result = Obj->[IDLgrBuffer::]QueryRequiredTiles( View, Image
  [, ALL_VISIBLE=value] [, COUNT=variable] [, PATH=objref(s)])
```

Return Value

Returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.

Table 31-4: IDLIMAGETILE Structure

Field	Data Type	Description
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 31-4: IDLIMAGETILE Structure (Continued)

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 31-1: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note

See “[Image Tiling](#)” (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.

Arguments

View

An object reference to the `IDLgrView` object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled `IDLgrImage` object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if `QueryRequiredTiles` should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of PATH, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the PARENT properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

6.2	Introduced
7.0	Added PATH keyword to QueryRequiredTiles to handle aliases.

IDLgrBuffer::Read

The IDLgrBuffer::Read function method reads an image from a buffer. The returned value is an instance of the [IDLgrImage](#) object class.

Syntax

```
Result = Obj->[IDLgrBuffer::]Read()
```

Return Value

Returns an instance of the [IDLgrImage](#) object class.

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrBuffer::Select

The IDLgrBuffer::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

```
Result = Obj->[IDLgrBuffer::]Select(Picture, XY [, DIMENSIONS=[width, height]]  
    [, /ORDER] [, SUB_SELECTION=variable] [, UNITS={0 | 1 | 2 | 3}))
```

Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

Arguments

Picture

The view, viewgroup, or scene (an instance of the [IDLgrView](#), IDLgrViewgroup, or [IDLgrScene](#) class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

Keywords

DIMENSIONS

Set this keyword to a two-element array $[w, h]$ to specify that the selection box will have a width w and a height h , and will be centered about the coordinates $[x, y]$ specified in the XY argument. The box occupies the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

Any object which intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If $ORDER=0$ (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If $ORDER=1$, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

Tip

If you are using $DEPTH_TEST_FUNCTION=4$ (“less than or equal”) on your graphics objects, set $ORDER=1$ to return objects at the same depth in the order in which they appear visually.

SUB_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)
- Select targets (IDLgrModel objects with the $SELECT_TARGET$ property set)
- Graphic objects displayed at the given XY location

UNITS

Set this keyword to indicate the units of measure. Valid values are:

0	Device (default)
1	Inches
2	Centimeters
3	Normalized: relative to the dimensions of the graphics destination

Version History

5.0	Introduced
6.1	Added SUB_SELECTION keyword

IDLgrBuffer:: SetProperty

The IDLgrBuffer::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrBuffer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrBuffer Properties](#)” on page 3825 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrClipboard

An IDLgrClipboard object sends Object Graphics output to the operating system native clipboard or to a file in bitmap or vector format. The FILENAME, VECTOR, and POSTSCRIPT keyword values in the IDLgrClipboard::Draw method, and the platform on which the call is issued determine the file type and destination. See [IDLgrClipboard::Draw](#) for details.

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrClipboard::Init](#)” on page 3886.

Properties

Objects of this class have the following properties. See “[IDLgrClipboard Properties](#)” on page 3864 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrClipboard::Cleanup](#)
- [IDLgrClipboard::Draw](#)
- [IDLgrClipboard::GetContiguousPixels](#)
- [IDLgrClipboard::GetDeviceInfo](#)
- [IDLgrClipboard::GetFontnames](#)
- [IDLgrClipboard::GetProperty](#)
- [IDLgrClipboard::GetTextDimensions](#)
- [IDLgrClipboard::Init](#)
- [IDLgrClipboard::QueryRequiredTiles](#)
- [IDLgrClipboard::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

This example demonstrates the process of copying the contents of an IDL graphics display object (a buffer or a window) to the system clipboard, where it becomes available for pasting into another application. The example also uses the `IDLgrClipboard::Draw` method to create a platform-dependent file type in the current directory.

```
PRO SendingPlotToClipboard

; Determine the path to the "damp_sn2.dat" file.
signalFile = FILEPATH('damp_sn2.dat', $
    SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the data within the file.
signalSize = 512
signal = BYTARR(signalSize, /NOZERO)

; Open the file, read in data, and then close the file.
OPENR, unit, signalFile, /GET_LUN
READU, unit, signal
FREE_LUN, unit
```

```

; Determine viewplane size and margins.
offsetScale = 150.
viewOffset = offsetScale*[-1., -1., 1., 1.]
signalRange = MAX(signal) - MIN(signal)

; Initialize the display objects.
windowSize = [512, 384]
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = windowSize, $
    TITLE = 'Damped Sine Wave with Noise')

; Use an IDLgrViewgroup as the picture rather than
; an IDLgrView. This is used as a container for the
; "loose" objects, such as the IDLgrText objects that
; are the axis titles.
oViewgroup = OBJ_NEW('IDLgrViewgroup')

IDLgrClipboard Properties

IDLgrClipboard objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrClipboard::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrClipboard::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrClipboard::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure that contains the values of all of the retrievable properties associated with this object.

Property Type	Anonymous structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value or enumerated list item that determines whether to use the indexed color model for the clipboard buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color Index

Note

See “[Color and Destination Objects](#)” (*Object Programming*) for more information.

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the clipboard buffer in units specified by the UNITS property. The default is [640,480].

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphic tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the clipboard buffer's color lookup table.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrClipboard object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer value or enumerated list item indicating the rendering quality at which graphics are to be drawn to the clipboard buffer. Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A two-element floating-point vector of the form $[xres, yres]$ specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: $[0.035277778, 0.035277778]$ (72 DPI).

Note

To match screen rendering on an IDLgrClipboard object, the following properties should be matched between the devices: DIMENSIONS, UNITS, RESOLUTION, COLOR_MODEL and N_COLORS.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the clipboard object.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrClipboard::Cleanup

The IDLgrClipboard::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrClipboard::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrClipboard::Draw

The IDLgrClipboard::Draw procedure method draws the given picture to this graphics destination.

Writing to a File

The file type produced when the IDLgrClipboard::Draw method is passed an IDLgrView, IDLgrViewgroup, or IDLgrScene object varies depending upon keyword settings and the platform on which the call is issued. If the FILENAME keyword is set to a non-empty string, the name of the file IDL creates is specified by the string. If the FILENAME keyword is a non-zero, numeric value, IDL creates a file named `idl.ext` where `ext` is replaced with the appropriate extension shown in parentheses in the following table.

Keyword Settings	Windows File Type	UNIX File Type
VECTOR = 1, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 1, POSTSCRIPT = 0	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 1	Encapsulated PostScript (EPS)	Encapsulated PostScript (EPS)
VECTOR = 0, POSTSCRIPT = 0	Bitmap (BMP)	Encapsulated PostScript (EPS)

Table 31-5: File Types Produced by IDLgrClipboard Draw Method

Writing to the Clipboard

Objects can be written to the operating system clipboard using IDLgrClipboard::Draw. When the FILENAME keyword equals an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

Note

The IDLgrClipboard object empties the Windows clipboard before writing to it.

Note

When `VECT_SORTING=0`, objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them. Otherwise, objects are drawn to the destination device based on their average depth value.

Syntax

```
Obj->[IDLgrClipboard::]Draw [, Picture] [, /CMYK] [, FILENAME=string]
    [, /ISOLATIN1] [, POSTSCRIPT=value] [, VECT_SHADING={ 0 | 1 } ]
    [, VECT_SORTING={ 0 | 1 } ]
    [, VECT_TEXT_RENDER_METHOD={ 0 | 1 } ] [, VECTOR={ 0 | 1 } ]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

CMYK

This keyword has an effect only when the output format is Encapsulated PostScript (`POSTSCRIPT=1`). Set this keyword to create a PostScript file using the CMYK (cyan, magenta, yellow, and black) color model. The default is a PostScript file using the RGB (red, green, blue) color model. This keyword applies to both bitmap and vector graphic PostScript files.

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

FILENAME

To write to a file, set this keyword as follows:

- Set to a string that represents the name of the file to which the output should be written.
- Set to any non-zero numerical value. IDL generates a filename based upon the values of the POSTSCRIPT and VECTOR keywords, and the platform. See [“Writing to a File”](#) in the introductory section for details.

If the value is an empty string (" "), equals 0 (zero), or is not specified, the output is written to the clipboard.

Note

You are strongly encouraged to specify a string for this value. The ability to specify a numerical value is maintained for backward compatibility, but its usage should be deprecated.

ISOLATIN1

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters. This keyword is ignored if the generated output is not PostScript.

POSTSCRIPT

Set this keyword to a non-zero value to indicate that the generated output should be in Encapsulated PostScript format. By default, the generated output is in Bitmap format on Windows platforms and Encapsulated PostScript on UNIX platforms.

VECT_SHADING

This keyword has an effect only when generating vector output (VECTOR=1) and when the output format is Encapsulated PostScript (POSTSCRIPT=1).

This keyword controls the appearance of smooth (Gouraud) shaded IDLgrPolygon and IDLgrSurface objects. Valid values are:

- 0 = disable smooth shading. This causes all polygons and surfaces to be rendered with flat shading. This may be valuable when using slower PostScript interpreters or when memory and stack space are limited. Smoothly shaded polygons require more resources as well as time.
- 1 = enable smooth shading (default). This renders smooth (Gouraud) shaded polygons and surfaces in the Encapsulated PostScript file.

Note

Polygons and surfaces in Enhanced MetaFiles (EMF) files will be rendered using flat shading. Only the output in Encapsulated PostScript (EPS) files is affected by this keyword, and only when the VECTOR keyword has been set. See [“Bitmap and Vector Graphic Output”](#) (Chapter 12, *Object Programming*) for details about vector graphic output.

VECT_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. The object primitives appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.
- 1 = enable sorting (default). The objects are ordered from back to front based on each primitive object’s average depth value.

Note

Objects that intersect each other, IDLgrImage objects (which do not update the depth buffer), and objects contained within transparent views might not sort correctly. See [“Controlling What is Displayed in Vector Graphics”](#) (Chapter 12, *Object Programming*).

VECT_TEXT_RENDER_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). The output device renders the text as text primitives. This allows the text to be edited by object-based graphics programs.
- 1 = render text as triangles. The text is rendered as a series of filled triangles in the vector file. This produces text that closely matches the text on the display device, but the output file size is larger, and the text can not be easily edited.

Note

The results of attempting to edit the text primitives depends upon the sophistication of the graphics program. An Enhanced MetaFile (EMF) inserted into a Microsoft Word document can be edited. However, not all versions of Microsoft Word support advanced 3-D graphic primitives such as those associated with obliquely or vertically aligned text. Choosing to edit a file with non-horizontally aligned text may result in the text being flattened into two dimensions. Typically, each letter becomes its own string and alignment is altered. To edit non-horizontal text and preserve the original quality, create an Encapsulated PostScript (EPS) file that can be modified in a more sophisticated object-oriented image editing program.

Note

See [“Text Rendering in Vector Graphics”](#) (Chapter 12, *Object Programming*) for more information.

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the clipboard or file in bitmap format. The bitmap retains the quality of the original image, but the bitmaps cannot be effectively scaled on all devices.
- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable. The vector representation does not retain all the attributes of the original image, but it can be effectively scaled on other devices. On Windows, the representation is the Windows Enhanced Metafile (EMF). On UNIX platforms, the representation is Encapsulated PostScript (EPS).

Note

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See [“Bitmap and Vector Graphic Output”](#) (Chapter 12, *Object Programming*) for a complete discussion of when to output to bitmap or vector graphics based on picture content.

Version History

5.1	Introduced
6.1	Added CMYK, VECT_SHADING, VECT_SORTING, and VECT_TEXT_RENDER_METHOD keywords
6.4	Added ISOLATIN1 keyword

IDLgrClipboard::GetContiguousPixels

The IDLgrClipboard::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

Syntax

```
Result = Obj->[IDLgrClipboard::]GetContiguousPixels()
```

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrClipboard::GetDeviceInfo

The IDLgrClipboard::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrClipboard::]GetDeviceInfo [, ALL=variable]  
    [, MAX_NUM_CLIP_PLANES=variable]  
    [, MAX_TEXTURE_DIMENSIONS=variable]  
    [MAX_TILE_DIMENSIONS=variable]  
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]  
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_TILE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TILE_DIMENSIONS contains a two element integer array that specifies the maximum tile size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

5.1	Introduced
-----	------------

5.6	Added MAX_NUM_CLIP_PLANES keyword
6.2	Added MAX_TILE_DIMENSIONS keyword

IDLgrClipboard::GetFontnames

The IDLgrClipboard::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrClipboard::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.1	Introduced
-----	------------

IDLgrClipboard::GetProperty

The IDLgrClipboard::GetProperty procedure method retrieves the value of a property or group of properties for the clipboard buffer.

Syntax

Obj->[IDLgrClipboard::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrClipboard Properties” on page 3864 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrClipboard::GetTextDimensions

The IDLgrClipboard::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in the clipboard buffer. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText `RECOMPUTE_DIMENSIONS` property.

Syntax

```
Result = Obj->[IDLgrClipboard::]GetTextDimensions( TextObj  
[, DESCENT=variable] [, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a text or axis object that will be rendered in the clipboard buffer.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrClipboard::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

5.1	Introduced
-----	------------

IDLgrClipboard::Init

The IDLgrClipboard::Init function method initializes the clipboard object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrClipboard' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrClipboard::]Init([, *PROPERTY=value*]) (*In a lifecycle method only.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrClipboard Properties” on page 3864 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrClipboard::QueryRequiredTiles

The IDLgrClipboard::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

Note

Clipboard support of tiled images is not available in vector mode (when the IDLgrClipboard::Draw method VECTOR keyword is set to 1).

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

Note

Tiled images are not supported when generating vector graphics for the clipboard. Bitmap mode (VECTOR=0) must be used when drawing tiled images to an IDLgrClipboard.

Note

If the device is in Color Index mode (COLOR_MODEL=1) or the image has [RENDER_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

Syntax

```
Result = Obj->[IDLgrClipboard::]QueryRequiredTiles( View, Image
  [, ALL\_VISIBLE=value] [, COUNT=variable] [, PATH=objref\(s\)] )
```

Return Value

Returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 31-6: IDLIMAGETILE Structure

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 31-2: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note

See “[Image Tiling](#)” (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.

Arguments

View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of PATH, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the PARENT properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

6.2	Introduced
7.0	Added PATH keyword to QueryRequiredTiles to handle aliases.

IDLgrClipboard:: SetProperty

The IDLgrClipboard::SetProperty procedure method sets the value of a property or group of properties for the clipboard buffer.

Syntax

Obj->[IDLgrClipboard::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrClipboard Properties](#)” on page 3864 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrColorbar

The IDLgrColorbar object consists of a color-ramp with an optional framing box and annotation axis. The object can be horizontal or vertical.

An IDLgrColorbar object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrcolorbar__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

[IDLgrModel](#)

- [IDLgrModel](#)
- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the IDLgrColorbar::Init method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for the axis and outline box. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

A two element integer vector [*dx*, *dy*] that specifies the size of the ramp display (not the axis) in pixels. If $dx > dy$, the colorbar is drawn horizontally with the axis placed below or above the ramp box depending on the value of the SHOW_AXIS property. If $dx < dy$, the colorbar is drawn vertically with the axis placed to the right or left of the ramp box depending on the value of the SHOW_AXIS property. The default value is [16,256].

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the `IDLgrColorbar::Init` method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MAJOR

An integer that represents the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

An object reference to an instance of the IDLgrPalette object class. If this property is a valid object reference, the colors within the IDLgrPalette are used to specify the colors for the colorbar.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrColorbar object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARENT

An object reference to the object that contains this colorbar.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RED_VALUES

A byte vector that contains the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the `IDLgrColorbar::Init` method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHOW_AXIS

An integer value that indicates whether the axis should be drawn:

- 0 = Do not display axis (the default)
- 1 = Display axis on left side or below the color ramp
- 2 = Display axis on right side or above the color ramp

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHOW_OUTLINE

A Boolean value indicating whether the colorbar bounds should be outlined:

- 0 = Do not display outline (the default)
- 1 = Display outline

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness used to draw the axis and box outline, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THREED

A Boolean value that determines whether to create the colorbar as a graphic object that can be fully transformed in three dimensions on initialization. By default, the colorbar always faces the viewer and is drawn at $z=0$.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKFORMAT

Either a standard IDL format string (see “*Format Codes*” (Chapter 18, *Application Programming*) for details on format codes) or a string containing the name of a user-supplied function that returns a string to be used to format the axis tick mark labels. The function should accept integer arguments for the direction of the axis, the index of the tick mark, and the value of the tick mark, and should return a string to be used as the tick mark’s label. The function may optionally accept a keyword called DATA,

which will be automatically set to the TICKFRMTDATA value. The default TICKFORMAT is "", the null string, which indicates that IDL will determine the appropriate format for each value.

Note

If the user-defined function's name does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether TICKUNITS is specified. For more information, see "[XYZ]TICKFORMAT" on page 5630.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKFRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT property, if any. By default, this value is undefined, indicating that the DATA property will be undefined (and furthermore, need not be supported by the user-supplied function). Note that TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrColorbar::GetProperty method.

Property Type	Scalar of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKTEXT

An object reference to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (each with a single string) that specifies the annotations to be assigned to the tick marks. By default, TICKTEXT is set to the NULL object, which indicates that IDL will compute tick annotations based upon the major tick values. The positions and orientation of the provided text object(s) may be overwritten by the colorbar.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrColorbar object is destroyed.

Property Type	Object reference or object reference vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TICKVALUES

A floating-point vector of data values that represent the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrColorbar object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ specifying the range of the x data coordinates covered by the colorbar.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the colorbar.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors that converts *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of the *Z* data coordinates covered by the colorbar.

Note

Until the colorbar is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the colorbar object to get the data dimensions of the colorbar prior to a draw operation.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrColorbar::Cleanup

The IDLgrColorbar::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrColorbar::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrColorbar::ComputeDimensions

The IDLgrColorbar::ComputeDimensions function method retrieves the dimensions of a colorbar object for the given destination object. In order to compute the effective dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a three-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the colorbar object measured in data units.

Syntax

```
Result = Obj->[IDLgrColorbar::]ComputeDimensions( DestinationObj  
[, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a colorbar object for the given destination object.

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the colorbar are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrColorbar::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

5.1	Introduced
-----	------------

IDLgrColorbar::GetProperty

The IDLgrColorbar::GetProperty procedure method retrieves the value of a property or group of properties for the colorbar.

Syntax

Obj->[IDLgrColorbar::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrColorbar Properties” on page 3896 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrColorbar::Init

The IDLgrColorbar::Init function method initializes the colorbar object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLgrColorbar' [, aRed, aGreen, aBlue] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrColorbar::]Init([aRed, aGreen, aBlue] [, PROPERTY=value])  
(In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *aRed*, *aGreen*, and *aBlue* arguments are used to initialize the value of the [RED_VALUES](#), [GREEN_VALUES](#), and [BLUE_VALUES](#), properties of the IDLgrColorbar object.

Note

If *aRed*, *aGreen*, and *aBlue* are not provided, the color palette will default to a 256 entry greyscale ramp.

aRed

A vector containing the red values for the color palette. These values should be within the range of $0 < Value < 255$. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of $0 < Value < 255$. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of $0 < Value < 255$. The number of elements comprising the *aBlue* vector must not exceed 256.

Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 3896 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrColorbar::SetProperty

The IDLgrColorbar::SetProperty procedure method sets the value of a property or group of properties for the colorbar.

Syntax

Obj->[IDLgrColorbar::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrColorbar Properties](#)” on page 3896 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrContour

The IDLgrContour object draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created.

An IDLgrContour object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

The object stores the following argument or property in double-precision if the DOUBLE_DATA property is specified, and in single-precision otherwise.

Superclasses

- IDLitComponent

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object except DATA_VALUES and GEOM.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the contour. The default value of 1.0 causes IDL to draw the contours completely opaque. If the value of this property is less than 1.0, then the pixels of the contours are blended with the pixels already on the screen, where the color of the contour is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This property has no effect on devices using indexed color

mode. If contour colors (C_COLOR property) are supplied, then the value of this property is used for the contour alpha if the C_COLOR property does not contain alpha values (3-channel RGB colors). If the C_COLOR property does contain alpha values (4-channel RGBA colors), then the alpha from each contour color is used. When contour labels (either text or symbols) are used and a label's corresponding value in the C_USE_LABEL_COLOR property is zero, the value of this property is used for the label alpha if contour colors are not provided or if the contour colors are provided and do not contain alpha values. If the alpha values are supplied in the C_COLOR property, then each label uses the alpha from its corresponding C_COLOR contour color. When contour labels (either text or symbols) are used and a label's corresponding value in the C_USE_LABEL_COLOR property is non-zero, then the value of the label object's ALPHA_CHANNEL property is used to draw the label. In other words, C_USE_LABEL_COLOR also implies using the label object's alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AM_PM

A string vector of two values indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL_FORMAT property.

Property Type	String vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ANISOTROPY

A three-element floating-point vector $[x, y, z]$ that represents the multipliers to be applied to the internally computed correction factors along each axis that account for

anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range [*xmin*, *ymin*, *zmin*] to [*xmax*, *ymax*, *zmax*], then the default correction factors are computed as follows:

```

dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
    xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
    ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
    zcorrection = maxRange / dz

```

This internally computed correction is then multiplied by the corresponding [x, y, z] values of the ANISOTROPY property. The default value for this property is [1,1,1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Anistrophy		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_COLOR

A vector of colors to be used to specify the color of each contour level. The vector may be of the form [*n*] where each entry is a color index, or of the form [3,*n*] where each 3-element row is an RGB color, or of the form [4,*n*] where each 4-element row is an RGBA color. To remove contour colors after they have been set, set C_COLOR to a scalar.

If C_COLOR is not specified, the entire contour plot is drawn in the single color provided by the COLOR property, which is the default action. If there are no contour colors, GetProperty returns a value of -1 for this property.

If there are more contour levels than elements in C_COLOR, the elements of C_COLOR are cyclically repeated.

Property Type	USERDEF		
Name String	Colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_FILL_PATTERN

An array of IDLgrPattern objects that represent the patterns to be applied at each contour level if the FILL property is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this property is set to any scalar value, all contour levels are filled with a solid color (this is the default). If there are no fill pattern objects stored in this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Fill patterns		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_LABEL_INTERVAL

A floating-point vector that indicates the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C_LABEL_INTERVAL values will be repeated cyclically. The default is 0.4.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_NOGAPS

An integer vector that indicates whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_NOGAPS values will be repeated cyclically.

By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_OBJECTS

An array of object references that provides examples of labels to be drawn for each contour level. The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C_LABEL_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values. Note that the objects specified via this property are used as descriptors only. The actual objects drawn as labels are generated by IDL, and may be accessed via the IDLgrContour::GetLabelInfo method. The contour labels will have the same color as the corresponding contour level (see C_COLOR) unless the C_USE_LABEL_COLOR property is specified. The orientation of the label will be automatically computed unless the C_USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

Note

The object(s) set via this property will not be destroyed automatically when the contour is destroyed.

Property Type	Object reference array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LABEL_SHOW

An integer vector that indicates whether labels are shown. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_LINestyle

An integer array of linestyles that represent the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this property is set to any scalar value, all levels are drawn as solid lines (this is the default). If there are no linestyles specified for this property, GetProperty will return a value of -1.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Linestyles		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_THICK

A floating-point array of line thicknesses that represent the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated. If this property is set to any scalar value, all contour levels are drawn with a line thickness of 1.0 points (this is the default). If there are no thicknesses specified for this property, GetProperty will return a value of -1.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Thicknesses		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

C_USE_LABEL_COLOR

An integer vector that indicates whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C_COLOR property for the contour object will be used instead.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

When user-defined IDLgrSymbol objects are used for labels in an IDLgrContour object and C_USE_LABEL_COLORS is set to non-zero values, all properties including the color are defined by the object composing the user-defined symbol, and not from the values set on the symbol object itself. For example, a green bow

tie-shaped IDLgrPolyline is assigned to the symbol object, and this symbol object is assigned to the C_LABEL_OBJECTS property. If C_USE_LABEL_COLOR is set, there will be green bow tie shaped labels on the contour lines. If C_USE_LABEL_COLOR is not set, the bow tie color is defined by C_COLOR. Properties defined on the symbol object itself are ignored in all cases.

C_USE_LABEL_ORIENTATION

An integer vector that indicates whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_ORIENTATION values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

C_VALUE

A floating-point value or a floating-point vector for which contour values are to be drawn. Setting ONLY a scalar value of 0 will cause the default action of even sampling of contour levels across the DATA_VALUES, using the value of the N_LEVELS property to determine the number of samples. IDL will convert any other scalar value to a single element vector containing that value and will then use it as if the user had supplied it as a vector. If there are no values specified for this property, GetProperty will return a value of -1. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Level values		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` keyword of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used to draw the contours. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0,0,0]. This value will be ignored if the `C_COLOR` property is set to a vector.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA_VALUES

A floating-point vector or two-dimensional array that specifies the values to be contoured. The property is the same as the *Values* argument described in “IDLgrContour::Init” on page 3954. IDL converts and stores this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA property is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DAYS_OF_WEEK

A string vector of 7 values that indicates the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the LABEL_FORMAT property.

Property Type	String vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

Use this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple `DEPTH_OFFSET` values. It is safest to use only a `DEPTH_OFFSET` value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of `DEPTH_OFFSET` values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of `DEPTH_OFFSET` values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use `DEPTH_OFFSET`.

Note

`DEPTH_OFFSET` has no effect unless the `FILL` property is set.

Property Type	Integer		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE_DATA

A Boolean value that indicates whether the object is to store data provided by either the *Values* argument or the DATA_VALUES property parameter in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any value data already stored in the object to the requested precision, if necessary.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE_GEOM

A Boolean value that indicates whether the object is to store data provided by any of the GEOMX, GEOMY, or GEOMZ property parameters in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any geometry data already stored in the object to the requested precision, if necessary.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOWNHILL

A Boolean value or enumerated list item that indicates whether downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

Value	Property Sheet Value	Description
0	Hide	Do not render downhill tick marks (the default)
1	Show	Render downhill tick marks

Property Type	ENUMLIST		
Name String	Downhill ticks		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL

A Boolean value that indicates whether the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contour may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

Property Type	Boolean		
Name String	Fill contours		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GEOM

A floating-point array that contains the geometry associated with the contour. IDL returns this data in single-precision floating-point by default or in double-precision floating-point if the `DOUBLE_GEOM` property is set in the `IDLgrContour::Init` method.

The shape of the data contained in GEOM depends on the value of the `GEOMZ` property (and potentially the `GEOMX` and `GEOMY` properties). The following rules apply:

- If `GEOMZ` is a vector of Z values $[z_0, z_1, z_2, \dots]$ (in which case it is presumed that `GEOMX` and `GEOMY` were also set as vectors), `GEOM` will contain a $3 \times N$ array of XYZ values: $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$.
- If `GEOMZ` is a $3 \times N$ array of XYZ values $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$, `GEOM` will contain a $3 \times N$ array of XYZ values: $[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots]$.
- If `GEOMZ` is an $N \times M$ array of Z values $[[z_0, z_1, z_2, \dots], [z_N, z_{N+1}, z_{N+2}, \dots], \dots]$ (in which case it is presumed that `GEOMX` and `GEOMY` were also set as $N \times M$ arrays), `GEOM` will contain a $3 \times N \times M$ array of XYZ values: $[[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots], [x_N, y_N, z_N], \dots], \dots]$
- If `GEOMZ` is a scalar and the `PLANAR` property contains a `True` value (in which case it is presumed that `DATA_VALUES` was set as an $N \times M$ array), `GEOM` will contain a $3 \times N \times M$ array of XYZ values: $[[[x_0, y_0, z_0], [x_1, y_1, z_1], \dots], [x_N, y_N, z_N], \dots], \dots]$
- If `GEOMZ` is a scalar and the `PLANAR` property contains a `False` value, `GEOM` will be undefined.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

GEOMX

A floating-point vector or two-dimensional array that specifies the X coordinates of the geometry with which the contour values correspond. If X is a vector, it must match the number of elements in the *Values* argument to the [IDLgrContour::Init](#) method or DATA_VALUES property value, or it must match the first of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the X coordinates will be repeated for each row of data values). IDL converts and maintains this data as double-precision floating-point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

GEOMY

A floating-point vector or two-dimensional array specifying the Y coordinates of the geometry with which the contour values correspond. If Y is a vector, it must match the number of elements in the *Values* argument to the [IDLgrContour::Init](#) method or DATA_VALUES property value, or it must match the second of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the Y coordinates will be repeated for each column of data values). IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is

stored in single precision. IDL returns the data as double precision if it was stored in double precision.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

GEOMZ

A floating-point scalar, a vector, or a two-dimensional array specifying the Z coordinates of the geometry with which the contour values correspond.

- If GEOMZ is a scalar and the PLANAR property contains a True value, the resulting contour geometry will be projected onto the plane $Z=GEOMZ$. If GEOMZ is a scalar, and the PLANAR property is not set, any geometry associated with the contour will be freed.
- If GEOMZ is a vector of Z coordinates, the number of elements in the vector should be the same as the number of elements in DATA_VALUES.
- If GEOMZ is an array and the leading dimension is 3, then the data is treated as a list or array of 3-D vertices. The product of the array dimensions following the 3 should equal the number of DATA_VALUES.
- If GEOMZ is an array and the leading dimension is not 3, then the data is treated as a list or array of single Z coordinates. If the number of dimensions is 2, then the data is treated as a 2-D array of Z values. Otherwise, it is treated as a vector of Z values. In either case, the total number of elements in the array should be the same as the number of DATA_VALUES.
- If GEOMZ is not set, the geometry will be derived from the DATA_VALUES property (if it is set to a two-dimensional array). In this case, the connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero.

Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

Property Type	Floating-point scalar, vector, or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LABEL_FONT

An object reference to an IDLgrFont object that describes the default font to be used for contour labels. This font will be used for all text labels automatically generated by IDL (i.e., if C_LABEL_SHOW is set but the corresponding C_LABEL_OBJECTS text object is not provided), or for any text label objects provided via C_LABEL_OBJECTS that do not already have the font property set. The default value for this property is a NULL object reference, indicating that 12 pt. Helvetica will be used.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrContour object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_FORMAT

A string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: Axis, Index, and Value, where:

- Axis is simply the value 2 to indicate that values along the Z axis are being formatted. (This allows a single callback routine to be used for both axis labeling and contour labeling.)
- Index is the contour level index (indices start at 0).
- Value is the data value of the current contour level.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_FRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the LABEL_FORMAT property, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

Note

LABEL_FRMTDATA will not be included in the structure returned via the ALL property to the IDLgrContour::GetProperty method.

Property Type	Scalar of any type		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

LABEL_UNITS

A string that indicates the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

Note

The singular form of each of the time unit strings is also acceptable (for example, LEVEL_UNITS='Day' is equivalent to LEVEL_UNITS='Days').

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MAX_VALUE

A floating point value that indicates the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MONTHS

A string vector of 12 values indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C_LABEL_FORMAT keyword.

Property Type	String vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MIN_VALUE

A floating-point value that indicates the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

N_LEVELS

An integer value that indicates the number of contour levels to generate. This property is ignored if the C_VALUE property is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this

property to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

Property Type	INTEGER		
Name String	Number of levels		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrContour object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: No	Set: No	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this contour.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PLANAR

A Boolean value or enumerated list item that indicates whether the contoured data is to be projected onto a plane. This property is ignored if GEOMZ is not a scalar.

Value	Property Sheet Value	Description
0	Planar	Any geometry associated with the contour will be freed
1	Three-D	Projects the contoured data onto a plane at the Z locations provided by the GEOMZ property (the default)

Property Type	ENUMLIST		
Name String	Projection		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

POLYGONS

An integer array of polygon descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument or the DATA_VALUES property). A polygon description is an integer or long word array of the form: $[n, i0, i1, \dots, in-1]$, where n is the number of vertices that define the polygon, and $i0..in-1$ are indices into the X, Y, and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, n , to 0. To end the drawing list, even if additional array space is available, set n to -1. If this property is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the contour is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional contour objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer value or enumerated list item that indicates the type of shading to use:

Value	Property Sheet Value	Description
0	Flat	The color has a constant intensity for each face of the contour, based on the normal vector (the default)
1	Gouraud	The colors are interpolated between vertices, and then along scanlines from each of the edge intensities

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKINTERVAL

A floating-point value that indicates the distance between downhill tickmarks, in data units. If TICKINTERVAL is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Downhill tick interval		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TICKLEN

A floating-point value that indicates the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the

length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

Property Type	FLOAT		
Name String	Downhill tick length		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the C_LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the label IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[x_{min}, x_{max}]$ specifying the range of the X data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form $[y_{min}, y_{max}]$ that specifies the range of the Y data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form $[z_{min}, z_{max}]$ that specifies the range of the Z data coordinates covered by the contour.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrContour::AdjustLabelOffsets

The IDLgrContour::AdjustLabelOffsets procedure method adjusts the offsets at which contour labels are positioned.

Syntax

Obj->[IDLgrContour::]AdjustLabelOffsets, *LevelIndex*, *LabelOffsets*

Arguments

LevelIndex

The index of the contour level for which the label offsets are being adjusted. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS property in the IDLgrContour::Init method).

LabelOffsets

A scalar or vector of floating point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each contour line at which each label is to be positioned. The number of elements in this vector must exactly match the number of elements returned in the LABEL_OFFSETS vector retrieved via the IDLgrContour::GetLabelInfo method for the same level.

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrContour::Cleanup

The IDLgrContour::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrContour:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrContour::GetCTM

The IDLgrContour::GetCTM method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrContour::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref] )
```

Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrContour::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.1	Introduced
-----	------------

IDLgrContour::GetLabelInfo

The IDLgrContour::GetLabelInfo procedure method retrieves information about the labels for a contour. The returned information is only valid until the next time the C_LABEL_INTERVAL or C_LABEL_OBJECTS property is modified using the IDLgrContour::SetProperty method, or the offsets are adjusted using the IDLgrContour::AdjustLabelOffsets method.

Syntax

```
Obj->[IDLgrContour::]GetLabelInfo, Destination, LevelIndex  
    [, LABEL_OFFSETS=variable] [, LABEL_POLYLINES=variable]  
    [, LABEL_OBJECTS=variable]
```

Arguments

Destination

A reference to a destination object (such as an IDLgrWindow or IDLgrBuffer object). The contour label information will be computed so that the requested font size is satisfied for this destination device.

LevelIndex

The index of the contour level for which the label information is being requested. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS keyword in the IDLgrContour::Init method).

Keywords

LABEL_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of floating point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each contour line at which the contour labels are positioned.

LABEL_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of contour polyline indices, [P₀, P₁, ...], that indicate which contour lines are labeled. P_i corresponds to the ith contour line.

Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

LABEL_OBJECTS

Set this keyword to a named variable that upon return will contain a vector of objects that represent the labels for each contour label.

Version History

5.1	Introduced
-----	------------

IDLgrContour::GetProperty

The IDLgrContour::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrContour::](#)GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrContour Properties](#)” on page 3918 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrContour::Init

The IDLgrContour::Init function method initializes the contour object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrContour' [, Values] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrContour::]Init([Values] [, PROPERTY=value])  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Values

A vector or two-dimensional array of values to be contoured. If no values are provided, the values will be derived from the GEOMZ property value (if set and the PLANAR property is not set). In this case, the values to be contoured will match the Z coordinates of the provided geometry. IDL converts and maintains this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

Keywords

Any property listed under “[IDLgrContour Properties](#)” on page 3918 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrContour:: SetProperty

The IDLgrContour:: SetProperty procedure method sets the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrContour::] SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “IDLgrContour Properties” on page 3918 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrFilterChain

An IDLgrFilterChain object is a specialization of the IDL_Container object that is designed to execute a sequence of image filtering shader objects according to their container order. The chain of shader objects must be “image filtering” shaders (those designed to modify an IDLgrImage object). To apply a chain of shaders to an image, set the IDLgrImage SHADER property equal to the filter chain object. Only shader objects (IDLgrShader objects and objects subclassing from IDLgrShader) can be added to the IDLgrFilterChain. See “[IDLgrShader](#)” on page 4335 for more information about shader objects.

When the sequence of shaders are executed, the output from the first shader is passed to each subsequent shader in the chain until the last shader is reached, the result of which is drawn to the destination device.

Note

This functionality requires support for OpenGL frame buffer object extension in addition to the standard hardware support require by IDLgrShader. See the [IDLgrWindow::GetDeviceInfo](#) methods’s [FRAMEBUFFER_OBJECT_EXTENSION](#) keyword for details).

Note

To control the precision of the temporary storage used to pass data between shaders, use the [OUTPUT_DATA_TYPE](#) property of IDLgrShader.

If the GPU hardware does not provide sufficient support or if FORCE_FILTER is set, the software fallback is used. In such cases, the IDLgrShader::FILTER method (if provided) will be called for each shader in the filter chain. The array returned from FILTER must have the same dimensions as the incoming image. If the returned array from any IDLgrShader in the chain does not meet these requirements IDL draws the image with its original data. See “[Providing a Software Alternative to Shaders](#)” (Chapter 14, *Object Programming*) for details.

Warning

Setting IDLgrImage [RENDER_METHOD](#)=1 (do not render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

Superclasses

[IDL_Container](#)

Creation

See “[IDLgrFilterChain::Init](#)” on page 3962.

Properties

Objects of this class have the following properties. See “[IDLgrFilterChain Properties](#)” on page 3959 for details on individual properties.

- [FORCE_FILTER](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrFilterChain::Cleanup](#)
- [IDLgrFilterChain::GetProperty](#)
- [IDLgrFilterChain::Init](#)
- [IDLgrFilterChain::SetProperty](#)

In addition, this class inherits the methods of its superclass ([IDL_Container](#)).

Examples

See “[Image Filter Shaders](#)” (Chapter 14, *Object Programming*) for examples.

IDLgrFilterChain Properties

IDLgrFilterChain objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrFilterChain::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrFilterChain::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrFilterChain::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [FORCE_FILTER](#)

In addition, objects of this class inherit the properties of [IDL_Container](#).

FORCE_FILTER

Set this scalar long property to a non-zero value to cause IDL to call the IDLgrShader subclass Filter method on each object in this filter chain, even if there is hardware shader support in the current device. This property overrides the FORCE_FILTER property on the shader objects contained in the filter chain. This is useful for developing and testing the software fallback option on devices that have the hardware support. The default value for this property is zero. This property can only be set at Init time.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLgrFilterChain::Cleanup

The IDLgrFilterChain::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrFilterChain::]Cleanup (In a lifecycle method only.)

IDLgrFilterChain::GetProperty

The IDLgrFilterChain::GetProperty procedure method retrieves the value of a property or group of properties for this object.

Syntax

Obj->[IDLgrFilterChain::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrFilterChain Properties” on page 3959 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

6.4	Introduced
-----	------------

IDLgrFilterChain::Init

The IDLgrFilterChain::Init function method initializes the filter chain object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrFilterChain' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrFilterChain::]Init( [, PROPERTY=value])  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrFilterChain Properties](#)” on page 3959 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

6.4	Introduced
-----	------------

IDLgrFilterChain:: SetProperty

The IDLgrFilterChain::SetProperty procedure method retrieves the value of a property or group of properties for this object.

Syntax

Obj->[IDLgrFilterChain::]SetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrFilterChain Properties” on page 3959 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Any keyword not recognized is passed to this object’s superclass.

6.2	Added UVALUE property

IDLgrFont Properties

IDLgrFont objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrFont::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrFont::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrFont::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [NAME](#)
- [SIZE](#)
- [SUBSTITUTE](#)
- [THICK](#)
- [UVALUE](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

NAME

A string containing the name of the font used. See [“Fontname”](#) on page 3972 for details on constructing font name strings.

Specifying this property is the same as specifying the optional *Fontname* argument to the `IDLGrFont::Init` method.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SIZE

A floating-point value representing the point size of the font. The default is 12.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SUBSTITUTE

A string that indicates the font to use as a substitute if the specified *Fontname* is not available on the graphics destination. Valid values are only those fonts that are available on all destination objects (the fonts included with IDL). These are: 'Helvetica' (the default), 'Courier', 'Times', 'Symbol', or 'Hershey'.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, indicating the line thickness (measured in points) to use for the Hershey vector fonts. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrFont object is destroyed.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrFont::Cleanup

The IDLgrFont::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrFont::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrFont::GetProperty

The IDLgrFont::GetProperty procedure method retrieves the value of a property or group of properties for the font.

Syntax

Obj->[IDLgrFont::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrFont Properties” on page 3967 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrFont::Init

The IDLgrFont::Init function method initializes the font object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Note

See “[Font Objects](#)” (Chapter 9, *Object Programming*) for information on creating and using font objects.

Syntax

```
Obj = OBJ_NEW('IDLgrFont' [, Fontname] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrFont::]Init([Fontname] [, PROPERTY=value])    (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Fontname

A string representing the name of the font to be used. This string should take the form 'fontname*modifier1*modifier2*...*modifierN'. All destination objects support the following fontnames: Helvetica, Courier, Times, Symbol, and Monospace Symbol. (These fonts are included with IDL; you may have other fonts installed on your system as well.)

Note

The value specified by the *Fontname* argument is used to initialize the value of the **NAME** property of the IDLgrFont object.

Valid modifiers for each of these fonts (except Symbol and Monospace Symbol) are:

- *Font weight*: Bold
- *Font angle*: Italic

For example, 'Helvetica*Bold*Italic'.

To select a Hershey vector font, use a fontname of the form: '*Hershey* fontnum*' where *fontnum* is the Hershey font's index number. See "[Hershey Vector Font Samples](#)" on page 5760 for descriptions of the Hershey vector fonts.

Note

Beginning with IDL version 5.1, only TrueType and Hershey fonts are supported in the Object Graphics system. See "[Fonts](#)" in Appendix H for details on these font systems.

Keywords

Any property listed under "[IDLgrFont Properties](#)" on page 3967 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrFont:: SetProperty

The IDLgrFont::SetProperty procedure method sets the value of a property or group of properties for the font.

Syntax

Obj->[IDLgrFont::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLgrFont Properties](#)” on page 3967 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrImage

An image object represents a mapping from a two-dimensional array of data values to a two dimensional array of pixel colors, resulting in a flat 2-D-scaled version of the image, drawn at $Z = 0$.

An IDLgrImage object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Beginning with IDL 6.2, IDLgrImage renders an image by default using a texture-mapped polygon on graphics devices using the RGB color model, for a significant increase in functionality and performance. IDL continues to use a 2D bitmap primitive to draw an image on devices using the indexed color model, since texture mapping is not available on such devices.

Note

With the texture-mapping performance improvements of 6.2, interpolation results may differ slightly across graphics devices and from pre-6.2 results. See [INTERPOLATE](#) for details.

Transformations of IDLgrImage Objects

By default, IDLgrImage objects are drawn at $Z=0$ and are positioned and sized with respect to two points:

$$p1 = [\text{LOCATION}(0), \text{LOCATION}(1), 0]$$

$$p2 = [\text{LOCATION}(0) + \text{DIMENSION}(0), \text{LOCATION}(1) + \text{DIMENSION}(1), 0].$$

where `LOCATION` and `DIMENSION` are properties of the image object. These two points are transformed in three dimensions, and then projected onto the screen to form the opposite corners of a 2-D rectangle using screen space points designated as $p1'$ and $p2'$:

$$[[p1'[0], p1'[1]], [[p2'[0], p1'[1]],$$

$$[[p2'[0], p2'[1]], [[p1'[0], p2'[1]]]$$

The image data is drawn on the display as a 2-D image within this 2-D rectangle whose sides are parallel to the screen sides. The image data is *scaled* in two dimensions (not rotated) to fit into this projected rectangle and then drawn with Z buffering disabled.

To draw an image with the current full 3D transformation (the same way other objects such as polygons are transformed), set the IDLgrImage `TRANSFORM_MODE` property to 1. See the IDLgrImage [TRANSFORM_MODE](#) property for details.

Objects are drawn to a destination device in the order that they are added (via the Add method) to the model, view, or scene that contains them. By default, image objects do not take into account the depth locations of other objects that may be included in the view object unless you enable depth testing (see [“DEPTH_TEST_DISABLE”](#) (*IDL Reference Guide*) for details).

This means that objects that are drawn to the destination object (window or printer) after the image is drawn will appear to be in front of the image, even if they are located behind the image object. Since the image is drawn by default with depth testing disabled, you can think of the image primitive as ‘painting’ the image onto the screen without regard for other objects that might already have been drawn there.

This behavior can be changed by enabling depth testing to make the image primitive behave like other primitives such as polygons when they are drawn with depth testing enabled.

See [“Displaying Multiple Images in Object Graphics”](#) (Chapter 4, *Object Programming*) for an example using the LOCATION property.

Superclasses

[IDLitComponent](#)

Creation

See [“IDLgrImage::Init”](#) on page 4014.

Properties

Objects of this class have the following properties. See [“IDLgrImage Properties”](#) on page 3979 for details on individual properties.

- [ALL](#)
- [BLEND_FUNCTION](#)
- [CLIP_PLANES](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_FUNCTION](#)
- [DIMENSIONS](#)
- [HIDE](#)
- [ALPHA_CHANNEL](#)
- [CHANNEL](#)
- [DATA](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [GREYSCALE](#)
- [IMAGE_1D](#)

- INTERLEAVE
- INTERPOLATE
- ORDER
- PARENT
- RENDER_METHOD
- SHADER
- SUB_RECT
- TILE_COLOR
- TILE_DIMENSIONS
- TILE_NUM_LEVELS
- TILED_IMAGE_DIMENSIONS
- TRANSFORM_MODE
- XRANGE
- YRANGE
- ZRANGE
- INTERNAL_DATA_TYPE
- LOCATION
- PALETTE
- REGISTER_PROPERTIES
- RESET_DATA
- SHARE_DATA
- TILE_BORDER_SIZE
- TILE_CURRENT_LEVEL
- TILE_LEVEL_MODE
- TILE_SHOW_BOUNDARIES
- TILING
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrImage::Cleanup`
- `IDLgrImage::DeleteTileData`
- `IDLgrImage::GetCTM`
- `IDLgrImage::GetProperty`
- `IDLgrImage::Init`
- `IDLgrImage::ReadFilteredData`
- `IDLgrImage::SetProperty`
- `IDLgrImage::SetTileData`
- `IDLgrImage::TileDataLoaded`

In addition, this class inherits the methods of its superclasses (if any).

Examples

For image object examples see [Chapter 4, “Working with Image Objects”](#) (*Object Programming*). Also see [“Mapping an Image onto Elevation Data”](#) (Chapter 3, *Image Processing in IDL*) for a texture mapping example.

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.2	Removed NO_COPY property and documented it as an IDLgrImage::Init keyword. Added ALPHA_CHANNEL, DEPTH_OFFSET, RENDER_METHOD, TILE_COLOR, TILE_CURRENT_LEVEL, TILE_DIMENSIONS, TILE_LEVEL_MODE, TILE_NUM_LEVELS, TILE_SHOW_BOUNDARIES, TILED_IMAGE_DIMENSIONS, TILING, and TRANSFORM_MODE properties Added DeleteTileData and SetTileData methods
6.4	Added IMAGE_1D, INTERNAL_DATA_TYPE, SHADER, and TILE_BORDER_SIZE properties Added ReadFilteredData and TileDataLoaded methods

IDLgrImage Properties

IDLgrImage objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrImage::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrImage::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrImage::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties. See [“IDLgrImage Properties”](#) on page 3979 for details on individual properties.

- [ALL](#)
- [BLEND_FUNCTION](#)
- [CLIP_PLANES](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_FUNCTION](#)
- [DIMENSIONS](#)
- [HIDE](#)
- [INTERLEAVE](#)
- [INTERPOLATE](#)
- [ORDER](#)
- [PARENT](#)
- [RENDER_METHOD](#)
- [SHADER](#)
- [SUB_RECT](#)
- [TILE_COLOR](#)
- [TILE_DIMENSIONS](#)
- [TILE_NUM_LEVELS](#)
- [ALPHA_CHANNEL](#)

- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Note

This structure returns a COLOR property that is consistent with other graphic objects. However, as an image object's color depends on each sample of data, the concept of an overall COLOR is not meaningful for this object and is not used in rendering the object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the image. The default value of 1.0 causes IDL to draw the image completely opaque. If the value of this property is less than 1.0, then the pixels of the image are blended with the pixels already on the screen, where the image is blended according to the values in the BLEND_FUNCTION property.

Warning

If a **SHADER** is associated with the image object, the `ALPHA_CHANNEL` value is ignored.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color model.

If the image data contains an alpha channel, the effective alpha of each pixel is the pixel's alpha multiplied by the value in the `ALPHA_CHANNEL` property.

Since the `BLEND_FUNCTION` property contributes (along with the value of the `ALPHA_CHANNEL` property) to the control of the blending, be sure to set the `BLEND_FUNCTION` property to the desired value. Its default value is [0,0]. To obtain the same blending function used by other graphic objects using the `ALPHA_CHANNEL` property, set the `BLEND_FUNCTION` property to [3,4].

Property Type	Float-point value		
Name String	Opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BLEND_FUNCTION

A two-element integer vector that controls how the alpha channel values will be interpreted. Set this property equal to a two-element vector [*src*, *dst*] specifying one of the functions listed below for each of the source and destination objects. These are only valid for RGB model destinations. If an alpha channel is not specified in an image, the image's alpha blend factor is assumed to be 1.0. The values of the blending function (V_{src} and V_{dst}) are used in the following equation

$$C_d' = (V_{src} \cdot C_i) + (V_{dst} \cdot C_d)$$

where C_d is the initial color of a pixel on the destination device (the background color), C_i is the color of the pixel in the image, and C_d' is the resulting color of the pixel.

Setting *src* and *dst* in the BLEND_FUNCTION vector to the following values determine how each term in the equation is calculated:

src or dst	V_{src} or V_{dst}	What the function does
0	n/a	Alpha blending is disabled, which is the default setting. $C_d' = C_i$
1	1	The value of V_{src} or V_{dst} in the equation is one, thus the value of the term is the same as the color value.
2	0	The value of V_{src} or V_{dst} in the equation is zero, thus the value of the term is zero.
3	$Image_a$	The value of V_{src} or V_{dst} in the equation is the blend factor of the image's alpha channel.
4	$1 - Image_a$	The value of V_{src} or V_{dst} in the equation is one minus the blend factor of the image's alpha channel.

Table 31-7: Values for *src* and *dst* in BLEND_FUNCTION

For example, setting BLEND_FUNCTION = [3, 4] creates an image in which you can see through the foreground image to the background to the extent defined by the alpha channel values of the foreground image.

Since the alpha blending operation is dependent on the values of pixels already drawn to the destination for some blending functions, the final result may depend more on the order of drawing the images, and not necessarily on their relative location along the Z axis. IDL draws images in the order that they are stored in the IDLgrModel object that contains them.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Blend function		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CHANNEL

A hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, 'ff0000'X represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value 'ffffff'X.

Note

This property is ignored for CI destination objects.

This property is registered, but it is hidden by default.

Property Type	Integer		
Name String	Color channel		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions [4,*N*] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA

A $n \times m$, $2 \times n \times m$, $3 \times n \times m$, or $4 \times n \times m$ array (any type) of image data for the object. The n and m values may be in any position as specified by the INTERLEAVE property.

Specifying this property is the same as specifying the optional *ImageData* argument to the [IDLgrImage::Init](#) method.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

This property only has an effect when the image is rendered with a texture-mapped polygon and depth testing is enabled.

Set this property to an integer value that specifies an offset in depth to be used when rendering images. This offset is applied along the viewing axis, with positive values moving the image away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause an image to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of images at the same depth.

Note

Use this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This

can lead to portability problems because a set of `DEPTH_OFFSET` values may produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use `DEPTH_OFFSET`. However, software rendering may reduce the rendering performance of images displayed as texture-mapped polygons.

Property Type	Integer		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 (the default) to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

Note

To preserve backward compatibility with previous versions of IDL the default value of this property is different from that of other graphic objects using this property.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION`, `DEPTH_OFFSET`, and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

Set this property to a two-element integer vector of the form [*width, height*] specifying the dimensions of the rectangle in which the image is to be drawn on the device. The image will be resampled as necessary to fit within this rectangle. The default is derived from the dimensions of the given image data and is measured in pixels. IDL converts, maintains, and returns this data as double-precision floating-point.

Set this property to a scalar value to reset the image dimensions to the implicit dimensions of the data.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Draw dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

GREYSCALE

A Boolean value that determines whether the image is drawn through a palette.

0 = Use palette (the default).

1 = Do not use a palette.

This property only has an effect on single-band images. If this property is set to 1 and the destination color model is RGB, both the image palette (if present) and the destination device palette (if present) are bypassed, and the image is drawn in greyscale.

If the destination color model in Indexed, this property has no effect since the image pixels are copied directly to the device and are then translated to RGB by the device palette. The contents of the device palette determine the colors of the image on the display, which will be greyscale only if the device palette contains a grey ramp.

Note

Since it is difficult or impossible to map a greyscale image into an arbitrary color palette, this property has no effect on devices using the indexed color model,

Property Type	Boolean		
Name String	Grayscale		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw the graphic (the default)
1	False	Do not draw the graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

IMAGE_1D

A long value that indicates the image data is one-dimensional (1-D) as follows:

Value	Description
0	Not 1-D data (the default). Implies a normal 2-D image.
1	1-D data.

1-D images are useful for creating lookup table texture maps for use in fragment shaders (such as a [3,256] 1-D image used as a 256 entry RGB lookup table). 1-D images cannot be rendered by adding them to an `IDLgrModel` in a scene, but they can be passed to a shader program using [IDLgrShader::SetUniformVariable](#).

Note

You can set this property after an image object has been created, but the data must be of the correct dimensions. If needed, assign new data to the image using the [DATA](#) property.

An error is generated if this property is set to 1 and the image data array passed to the `IDLgrImage` is of the wrong dimensions. The accepted array dimensions are as follows where n is the number of array elements in the channel:

Interleave	Acceptable Arrays
Pixel	n — monochrome $2 \times n$ — monochrome and Alpha $3 \times n$ — R, G, B $4 \times n$ — R, G, B and Alpha
Planar	$n \times 2$ — monochrome and Alpha $n \times 3$ — R, G, B $n \times 4$ — R, G, B, and Alpha

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

INTERLEAVE

An integer value or enumerated list item that indicates the dimension over which color is interleaved for images with more than one channel:

Value	Property Sheet Value	Description
0	Pixel	Pixel interleaved images with dimensions $(3, m, n)$ - the default
1	Scanline	Scan line interleaved (row interleaved) images with dimensions $(m, 3, n)$
2	Planar	Planar interleaved images with dimensions $(m, n, 3)$

Note

If an alpha channel is present, the 3s should be replaced by 4s. In a greyscale image with an alpha channel, the 3s should be replaced by 2s.

This property is registered, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Interleaving		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTERNAL_DATA_TYPE

A long value that describes the data format used to store the image in the graphics hardware as a texture map. If floating-point data types are not supported by the graphics hardware, this value is ignored. In practice, this means that settings other than BYTE are generally useful only when using shader programs. Most shader implementations perform their computations in 32-bit float, so the value of this

property determines what precision is used to store the image data before it is converted to float and handed to the shader program. The default value is 0.

Value	Description of Internal Data Types
0	Byte — convert (truncate) and store as Byte. This setting is useful when the image data has a precision of 8 bits per image component or less.
1	Byte — data scaled to Byte
2	Float16 — store and maintain image data consisting of whole numbers in the range of +/- 2048. This is useful because this range uses less texture memory than FLOAT32. The largest values that can be stored with some loss of precision are +/- 65504.
3	Float32 — store whole numbers in the range +/- 16,777,216 without loss of precision and +/- 10^{38} with loss of precision. This format is useful if your image data is already in floating point format or if you have integer image data in the range +/- 16,777,216. This type, of course, requires 4 bytes per image pixel component, often 16 bytes per RGBA pixel.

Note

Hardware rendering performance on the GPU can be badly affected if bilinear interpolation (INTERPOLATE=1) is enabled when INTERNAL_DATA_TYPE is set to Float16 or Float32. In some cases, the graphics driver defaults back to software rendering.

The property is applied to data specified with the [DATA](#) property/ argument and the [TileData](#) argument of the SetTileData method. If no shader program is in effect this property is still used, however it is not recommended setting anything other than 0 unless you fully understand how OpenGL converts the input data to texture data. See “[OpenGL Conversion of Image Data to Texture Data](#)” (Chapter 14, *Object Programming*) for details.

When this property is non-zero, the image data provided to the object must be of one of the following types:

Type Code	Description	Values
1	BYTE	8-bit unsigned
2	INT	16-bit signed
4	FLOAT	32-bit float
12	UINT	16-bit unsigned

IDL type codes are listed in “[IDL Type Codes and Names](#)” on page 2385 under the `SIZE` function.

IDL execution halts with an error if any other type is provided. If you wish to change the `INTERNAL_DATA_TYPE` you must provide new data at the same time via the `DATA` property.

```
oImage->SetProperty, DATA=imagedata, INTERNAL_DATA_TYPE=2
```

IDL will not generate a warning if you fail to do this, but the image will be converted to a texture incorrectly.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

INTERPOLATE

An integer value or enumerated list item that determines whether to display the `IDLgrImage` object using bilinear interpolation. The default is to use nearest neighbor interpolation.

Value	Property Sheet Value	Description
0	Nearest neighbor	Surveys the value of the nearest pixel (the default)
1	Bilinear	Surveys the 4 closest pixels

See “[Interpolation Methods](#)” (Chapter 5, *Using IDL*) for details.

Property Type	ENUMLIST		
Name String	Interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

Note

Prior to IDL 6.2, IDL performed image interpolation using its own algorithms in software, if requested with the INTERPOLATE property. With the 6.2 performance enhancements, this interpolation is now performed by any texture-mapping acceleration hardware or fallback software in the vendor-supplied hardware and software. Therefore, interpolation results may differ slightly across graphics devices and from pre-6.2 results. To preserve the exact, but slower interpolation results delivered before IDL 6.2, set the RENDER_METHOD property to 1.

LOCATION

A two- or three-element floating-point vector $[x, y]$ or $[x, y, z]$ specifying the position of the lower lefthand corner of the image, measured in data units. If the vector is of the form $[x, y]$, then the z value is set equal to zero. The default is $[0, 0, 0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

On devices using the RGB color model, IDLgrImage renders the image using a texture-mapped polygon, and this polygon is subject to clipping by the near/far clip planes, as defined in the IDLgrView object. To define an arbitrary rotation for an image, see [TRANSFORM_MODE](#).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

See “[Positioning Image Objects in a View](#)” (Chapter 4, *Object Programming*) for an example using the LOCATION property.

ORDER

A Boolean value or enumerated list item that determines whether to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

Value	Property Sheet Value	Description
0	Bottom-to-top	Image data is drawn from the bottom row up to the top row (the default)
1	Top-to-bottom	Image data is drawn from the top row down to the bottom row

Tip

If you are reading a tiled JPEG2000 image using the `IDLffJPEG2000` object, using IDL's default ordering will result in the individual tiles being correctly oriented, but displayed out of sequence. To ensure that tiles are displayed in the correct sequence, set both the `ORDER` keyword to the `IDLffJPEG2000::GetData` method and the `ORDER` property of the `IDLgrImage` object to one.

Property Type	ENUMLIST		
Name String	Row order		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the `IDLgrPalette` object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

Warning

If a [SHADER](#) is associated with the image object, the palette is ignored.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrImage object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

See the “[Examples](#)” section of [IDLgrPalette](#) for examples of creating a palette object and assigning it to an image object.

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_METHOD

Set this property to 0 (the default) to cause the image to be rendered using a texture-mapped polygon whenever possible.

Set this property to 1 to cause the image to be rendered using a 2D pixel primitive. This is the mode used in versions of IDL prior to 6.2. When this method is used, the ALPHA_CHANNEL property is ignored and the full 3D transform mode (TRANSFORM_MODE property value 1) is not available.

Warning

Setting `RENDER_METHOD=1` (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative. See “IDLgrShader” on page 4335 for details.

The texture-mapped mode is more flexible and generally faster on devices with hardware texture mapping support.

This property has no effect on devices using the indexed color model, where the 2D pixel primitive method is always used.

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects.

- 0 = Overwrite data that is shared by other objects (the default).
- 1 = Treat DATA as a new data set unique to this object.

There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA

property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the image is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. If there is an error while applying the shader program, for example if the GLSL source does not compile, then the image will be displayed as if there were no shader specified. If a suitable graphics card is not present, IDL uses a software-based alternative if one has been provided in the shader object FILTER method. (See [“Providing a Software Alternative to Shaders”](#) (Chapter 14, *Object Programming*) for details.) A single IDLgrShader object may be associated with additional image objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

If a [PALETTE](#) has been set, the palette lookup is done before the fragment shader is executed. Therefore, when the fragment shader reads from the image texture it will be passed 8-bit per channel RGB data (read from the palette), not the original 1-channel image data.

Warning

If [RENDER_METHOD](#) is set to 1 (do *not* display images as texture-mapped polygons) then all shading is disabled. The SHADER property setting is completely ignored and the software fallback will not be used.

SHARE_DATA

An object reference to an object with which data is to be shared by this image. An image may only share data with another image. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrImage` object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SUB_RECT

A four-element floating-point vector, $[x, y, xdim, ydim]$, specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle to display, in pixel coordinates.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_BORDER_SIZE

A scalar long value that sets the size of the tile border. This is useful if the image is being filtered by an `IDLgrShader` that applies a convolution filter. Data from adjacent tiles is required when filtering the pixels along the edges of a tile. Setting `TILE_BORDER_SIZE` loads the required pixels from the adjacent tiles into the border of the current tile for computation purposes, but does not display them.

For example, if the convolution kernel size is 5x5, `TILE_BORDER_SIZE` should be set to 2. When a pixel on the top edge of a tile is being filtered, setting this property to two provides access to the two pixels above the current pixel (from the neighboring

tile) and the two pixels below the row. Likewise, if the kernel size is 3x3, `TILE_BORDER_SIZE` should be set to 1 to access all 9 pixels needed for the kernel.

The border size is subtracted from the `TILE_DIMENSIONS` making the visible tiles smaller. For example, if `TILE_DIMENSIONS` is 1024,1024 and `TILE_BORDER_SIZE` is 2, then the visible portion of the tile will be 1020,1020 (a 2-pixel border at each side of the image reduces the image size by 4).

If `TILE_BORDER_SIZE` is greater than 0 then the tile data requested by `QueryRequiredTiles` will include the border and `SetTileData` will expect the supplied data to include the border. The requested tiles will overlap because of the border.

IDL will automatically tile an image if its dimensions are larger than `MAX_TEXTURE_DIMENSIONS` returned by `GetDeviceInfo` (typically larger than 4096, 4096). (`TILING` need not be set in such a case.) However, if an `IDLgrShader` applies a convolution filter to such an image, you should still set `TILE_BORDER_SIZE` so that IDL will have the needed pixels for the convolution operation when handling the internally tiled data.

Default value is 0, the maximum value is `TILE_DIMENSIONS / 3`.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Given `TILE_DIMENSIONS` of 1024 by 1024 pixels and a `TILE_BORDER_SIZE=2`, the following figure shows the visible tiles (solid black lines) and the actual tile data that contains pixel from adjacent tiles (dotted lines).

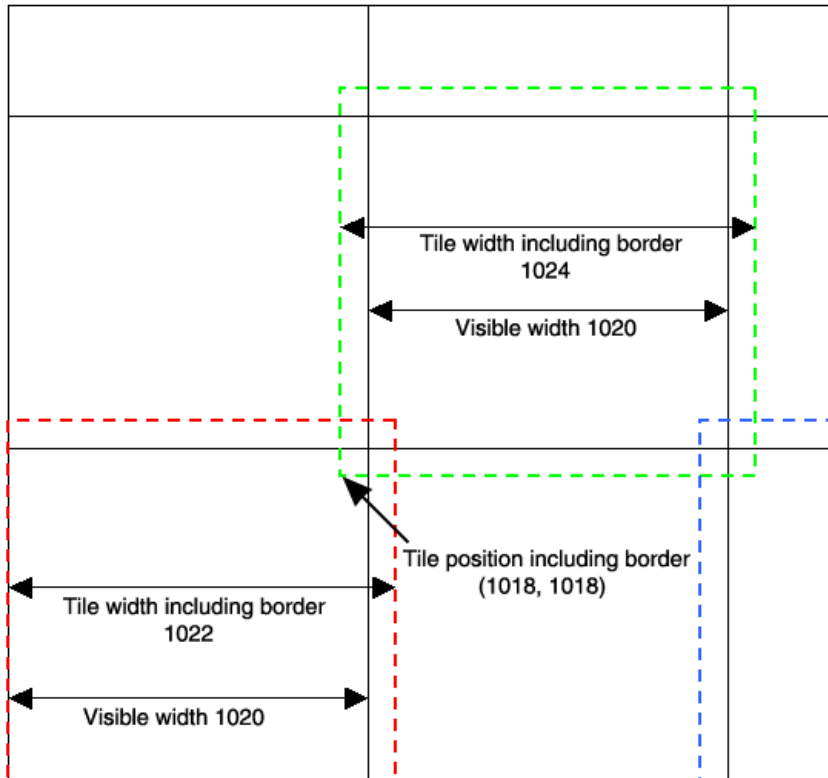

Figure 31-3: Visible Versus Actual Tile Data

TILE_COLOR

Set this property to a three- or four-element vector, `[red, green, blue]` or `[red, green, blue, alpha]`, specifying the color to draw the tile if no data has been set using [IDLgrImage::SetTileData](#). If alpha is not specified the value in `ALPHA_CHANNEL` will be used. `BLEND_FUNCTION` must be set for alpha to take effect. If data has

been set for the tile being drawn, or data from another level can be substituted, this property is ignored. The default is [0,0,0] (black).

Property Type	USERDEF		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_CURRENT_LEVEL

Set this property to an integer value that specifies the tile level that the destination object's QueryRequiredTiles method will request and use for drawing. The default is level 0, which is a tile from the full-resolution image. This property only applies when [TILE_LEVEL_MODE](#) is 0 (manual).

Property Type	INTEGER		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_DIMENSIONS

Set this property to a two-element integer vector specifying the dimensions of an image tile in the form of [*width, height*] in pixel units. The default value is [1024,1024]. Use this property to adjust the tile size to match your application's preferred tile size, if any. If the source of the tiled image data (e.g., image file or file server) has a default tile size, it will be most efficient to set this property to that tile size.

To determine the maximum allowable tile dimensions, use the MAX_TILE_DIMENSIONS keyword to the GetDeviceInfo method on the destination object (window, clipboard, or buffer object) to which the image will be drawn. If you set a TILE_DIMENSIONS value that exceeds the maximum tile dimension supported by the destination object, it will automatically be reduced to the maximum.

Note

Tile dimensions that are a power of 2 (e.g., 256, 512, 1024) are more memory efficient.

Property Type	USERDEF		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_LEVEL_MODE

Set this property to a scalar integer that defines the tile level selection mode. Use one of the following:

0	Manual mode. The application is responsible for setting the level to be used with TILE_CURRENT_LEVEL . The destination object's <code>QueryRequiredTiles</code> method always asks for and renders tiles at that specified level. This is the default. Use this mode if you <i>do not</i> have an image pyramid.
1	Automatic mode. The level to be requested and rendered is calculated by IDL based on image magnification or minification (the ratio of image pixels to screen pixels). Use this mode if you have an image pyramid and want images of different resolutions to be displayed based on zoom level.

Note

See [“Adding Tiling to Your Application”](#) (Chapter 4, *Object Programming*) for additional information.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_NUM_LEVELS

This property automatically calculates the number of image levels (resolution levels), or lets you set an integer value that specifies the number of levels in an image

pyramid that can be requested by the destination object's `QueryRequiredTiles` method. This is calculated automatically or can be set manually as follows:

Automatically calculated	<p>This is automatically calculated when the image is created such that the lowest resolution level is just smaller than the tile size. For example, if the level 0, full-resolution image is 5000 by 5000 and the tile size is 1024 by 1024 pixels:</p> <ul style="list-style-type: none"> • Level 1 will be 2500 by 2500 • Level 2 will be 1250 by 1250 • Level 3 will be 625 by 625 <p>Thus there are 4 levels (0 to 3), and level 3 is just smaller than the tile size. The default is to automatically calculate the number of levels based on <code>TILED_IMAGE_DIMENSIONS</code> and <code>TILE_DIMENSIONS</code> when the image is created.</p>
Manually set	<p>Set to an integer value specifying the number of levels. For example, setting 2 will result in <code>QueryRequiredTiles</code> requesting levels 0 and 1 as appropriate, and levels 0 and 1 being used for drawing as appropriate. This is useful if there are insufficient levels available in the image pyramid to match the calculated value of <code>TILE_NUM_LEVELS</code>.</p> <p>Set to 0 (zero) to use all available levels.</p>

Note

If this property is set to a value higher than the calculated value, it will be ignored, and the calculated value will be used.

This property is only used when `TILE_LEVEL_MODE` is set to 1 (automatic).

Property Type	INTEGER		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILE_SHOW_BOUNDARIES

Set this property equal to 1 to draw wireframe outlines around the tiles. This is useful while developing applications that use tiling to help visualize where the tiles are within the image. By default, this property is set equal to 0.

Property Type	Boolean		
Name String	Show tile boundaries		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILED_IMAGE_DIMENSIONS

Set this property to a two-element integer vector [*width*, *height*] specifying the pixel size of the original, full-resolution image that will be tiled. This property must be set when the [TILING](#) property set to non-zero value; otherwise, IDL generates an error. The default value is [0,0].

Note

Setting [TILED_IMAGE_DIMENSIONS](#) unsets the [TILE_NUM_LEVELS](#) property, meaning that the number of tile levels will be calculated automatically.

Property Type	USERDEF		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TILING

Set this property to 1 to enable tiling for this image object. The default value is 0 (no tiling). Use the destination object's `QueryRequiredTiles` method and the [IDLgrImage::SetTileData](#) method to determine tile visibility and load the appropriate data. Also, you must set [TILED_IMAGE_DIMENSIONS](#), changing the default value of [0,0] to the actual size of the image to be tiled to avoid generating an error.

Note

A tiled image cannot be drawn on a destination device using the indexed color model. Also, tiling is not permitted when the image property [RENDER_METHOD=1](#).

Property Type	BOOLEAN		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

When tiling is activated, the object does not use any data stored in its [DATA](#) property. However, the data are available and will be used if TILING is set to zero.

See “[Image Tiling](#)” (Chapter 4, *Object Programming*) for details on image tiling.

TRANSFORM_MODE

Set this property to 0 (the default) to cause the image to be rendered into a rectangular region whose sides are always parallel to the window’s sides. The rectangular region is defined by two points. The lower left point is specified by the [LOCATION](#) property. The upper right point is derived from the [LOCATION](#) property and either the [DIMENSIONS](#) property or the implicit image dimensions. These two points are transformed by the current model transform and are effectively projected onto a plane located at [LOCATION\[2\]](#) (default 0). The image is then drawn in this region. This is the mode used by versions of IDL prior to 6.2.

Set this property to 1 to cause the image to be rendered into an image rectangle where the entire image rectangle is transformed by the current full three-dimensional model transform. The image is rendered into the resulting rectangle, which may not be aligned with the window boundaries. This allows the image to be drawn with the full flexibility of the current model transform. For more information on transformations, see [Transformations of IDLgrImage Objects](#).

This property has no effect on devices using the indexed color model, where mode 0 is always used.

Property Type	ENUMLIST		
Name String	Transform mode		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

Two-element double-precision floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrImage::Cleanup

The IDLgrImage::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrImage::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrImage::DeleteTileData

The `IDLgrImage::DeleteTileData` procedure method removes tile data from the cache. This is useful to free up cache memory if the application knows a number of tiles will not be displayed again for some time. It could also be used if the image data changes and the old image data should be removed from the cache. If you remove a tile from the cache, a subsequent invocation of `QueryRequiredTiles` returns the tile if it is visible.

This method deletes tiles even if they were loaded with the `NO_FREE` keyword set. An error is generated if the tile argument does not specify a valid tile or the level argument specifies an invalid level. If the tile being deleted doesn't have any tile data, no error will be generated.

Syntax

Obj->[IDLgrImage::]DeleteTileData, *TileInfo* [, /ALL]

Arguments

TileInfo

A named structure describing the tile or tiles for which the data is being deleted. This structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.

Table 31-8: IDLIMAGETILE Structure

Field	Data Type	Description
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that is displaying the tiled IDLgrImage.

Table 31-8: IDLIMAGETILE Structure (Continued)

If a number of tiles are to be deleted by passing a region covering multiple tiles then X, Y, WIDTH and HEIGHT must be multiples of the tile size.

Keywords

ALL

Set this keyword to delete all tiles at all levels in the cache for this image. This is useful for clearing the cache when image data changes and new data will be loaded.

The new tile data may now have a different interleave format and number of channels than any tiles previously stored in the object. See [IDLgrImage::SetTileData](#).

Note

The *TileInfo* structure must still be passed, and must contain a valid destination object reference in the Dest field. The other entries can be 0 in this case.

Version History

6.2	Introduced
-----	------------

IDLgrImage::GetCTM

The IDLgrImage::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrImage::]GetCTM( [, DESTINATION=objref]  
    [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the image object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrImage::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrImage::GetProperty

The IDLgrImage::GetProperty procedure method retrieves the value of the property or group of properties for the image.

Syntax

```
Obj->[IDLgrImage::]GetProperty[, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 3979 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrImage::Init

The IDLgrImage::Init function method initializes the image object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrImage' [, ImageData] [, PROPERTY=value] [ ,NO_COPY])
```

or

```
Result = Obj->[IDLgrImage::]Init([ImageData] [, PROPERTY=value]
    [ ,NO_COPY])    (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

ImageData

An array of data values to be displayed as an image. Since by default IDL maintains the image data using the byte type, in most cases the input data values should range from 0 through 255. If this argument is not already of byte type, it is converted to byte type when the image object is created.

Note

The [INTERNAL_DATA_TYPE](#) property controls the type of data used to store *ImageData*. If the IDLgrImage object has an associated [IDLgrShader](#) object, it may be useful to use floating-point values to store the image data.

Image objects can have a single channel (one value per pixel—greyscale or color indexed), two channels (greyscale and alpha), three channels (red, green, and blue), or four channels (red, green, blue, and alpha). The alpha channel, if present, determines the transparency of the pixel. The `BLEND_FUNCTION` property controls the interpretation of the alpha channel values. With channels, the data value of 0 specifies minimum intensity and the data value of 255 specifies maximum intensity. The alpha channel values are also specified in the image data in the range 0 through 255, with an image data value of 0 corresponding to an alpha blend factor of 0 and an image data value of 255 corresponding to an alpha blend factor of 1.0. *ImageData* can be any of the following, where n is the width of the image, and m is the height:

- An $n \times m$ array of color lookup table indices.
- An $n \times m$ greyscale image, or a $2 \times n \times m$, $n \times 2 \times m$, or $n \times m \times 2$ greyscale image with an alpha channel. (The alpha channel is ignored if the destination device uses indexed color mode.)
- A $3 \times n \times m$, $n \times 3 \times m$, or $n \times m \times 3$ RGB image, or a $4 \times n \times m$, $n \times 4 \times m$, or $n \times m \times 4$ RGB image with an alpha channel.

If the array has more than one channel, the interleave is specified by the `INTERLEAVE` property.

Note

The value specified by the *ImageData* argument is used to initialize the value of the `DATA` property of the `IDLgrImage` object.

Keywords

Any property listed under “[IDLgrImage Properties](#)” on page 3979 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

NO_COPY

If this keyword is set to a non-zero value, it relocates the image data from the input variable to the image object, leaving the input variable *ImageData* undefined. Only the *ImageData* argument is affected. The following example illustrates that the data is moved from the input variable.

```
imgdata = BYTSCAL(DIST(300))
oImg = OBJ_NEW('IDLgrImage', imgData, /NO_COPY)
```

```
HELP, imgdata  
; IDL prints IMGDATA UNDEFINED = <Undefined>
```

If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrImage::ReadFilteredData

The `IDLgrImage::ReadFilteredData` function method returns image data after a shader program (contained in an [IDLgrShader](#) object or object subclassed from `IDLgrShader`) has been applied, or after one or more shaders (contained in an [IDLgrFilterChain](#) object) have been applied.

Note

If there is sufficient hardware support for `IDLgrShader` programs, this method will complete the shader operations and read the results generated by the graphic card's GPU (Graphic Processing Unit). If there is insufficient support or if software rendering has been specified, the software-based alternative will be used if you have provided one. See [“Providing a Software Alternative to Shaders”](#) (Chapter 14, *Object Programming*) for details.

Syntax

```
Result = Obj->[IDLgrImage::]ReadFilteredData( Dest [, DATA_TYPE=value]
    [, READ_POSITION=value] [, TILE=tileinfo] )
```

Return Value

Returns an array containing the filtered image data. The returned array is always of dimensions $[4, w, h]$ where w is the width of the returned image and h is the height. The data is always pixel interleaved RGBA. The type of the returned data is determined by the `DATA_TYPE` keyword.

If there was an error this method returns 0.

Arguments

Dest

A object reference to a graphics destination object, (e.g. `IDLgrWindow`).

Keywords

DATA_TYPE

Set this to one of the following allowable values to specify the data type of the returned data:

0	BYTE (default)
1	INT
2	FLOAT
3	UINT

The output of shader programs is always floating point so if 0, 1, or 3 is specified, the output is clamped to the range of 0.0 to 1.0 and then scaled to fill the requested data type range. If 2 is specified, the data is returned unmodified. The data is converted from floating point to the requested type as follows:

Requested Type	Conversion from Floating Point (f)
BYTE (0)	$c = (2^8-1)f$
INT (1)	$c = [(2^{16}-1)f - 1]/2$
FLOAT (2)	$c = f$
UINT (3)	$c = (2^{16}-1)f$

Note

It is very important that this keyword and the `IDLgrShader` `OUTPUT_DATA_TYPE` property are set in a consistent manner. For example, suppose you have `UINT` image data, but `OUTPUT_DATA_TYPE` is set to `BYTE` while `DATA_TYPE` is set to `UINT`. You will lose accuracy (due to the intermediate `BYTE` stage). In this example `OUTPUT_DATA_TYPE` should be set to `FLOAT32` (or possibly `FLOAT16` if only 10-bits of the `UINT` are used).

If not set, `BYTE` data is returned by default.

READ_POSITION

When the `IDLgrImage` [SHADER](#) property has been set to an `IDLgrFilterChain` object, set this keyword to a scalar long value specifying the zero-based position in the chain from which the data should be read.

For instance, if the filter chain contains a series of 3 shader objects, setting this keyword to one of the following values returns the specified data:

- 0 reads the result without any shaders applied
- 1 reads the result after application of only the first shader
- 2 reads the result after application of the first and second shaders
- 3 reads the result after application of all three shaders

If this keyword isn't set then the default behavior is to return the image data after application of all filtering shaders in the filter chain.

TILE

If the `IDLgrImage` is tiled (`TILING=1`) then this keyword must be set to a valid `IDLIMAGETILE` structure specifying the tile or tiles for which to return filtered data. For example, to retrieve the filtered data for the currently visible tiles call `IDLgrWindow::QueryRequiredTiles, /ALL_VISIBLE`, then for each tile call `ReadFilteredData`.

Note

Data must be loaded into the tiles using `IDLgrImage::SetTitleData` before doing this.

An error will be generated if the image is tiled and this keyword is not set to a valid `IDLIMAGETILE` structure.

Examples

Create an instance of the example object, `shader_rgb_doc`, which includes the ability to capture an image and display the results in `iImage`. Run the example by creating an instance of the object at the IDL command prompt using `orgbshader=OBJ_NEW("shader_rgb_doc")` or view the file in an IDL Editor window by entering `.EDIT shader_rgb_doc__define`.

Version History

6.4	Introduced
-----	------------

IDLgrImage:: SetProperty

The IDLgrImage::SetProperty procedure method sets the value of the property or group of properties for the image.

Syntax

Obj->[IDLgrImage::]SetProperty[, PROPERTY=value] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under “IDLgrImage Properties” on page 3979 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

NO_COPY

If this keyword is set to a non-zero value, and the **DATA** property is specified in the same invocation, it relocates the image data from the input variable to the image object, leaving the input DATA property variable undefined. Only the DATA property is affected. The following example illustrates that the data is moved from the input variable.

```
imgdata = BYTSCL(DIST(300))
oImg = OBJ_NEW('IDLgrImage')
oImg->SetProperty, DATA=imgdata, /NO_COPY
HELP, imgdata
; IDL prints IMGDATA UNDEFINED = <Undefined>
```

If this keyword is omitted, the input image data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrImage::SetTileData

The IDLgrImage::SetTileData procedure method stores tile data in the IDLgrImage tile data cache. If a tile has data loaded but not for the required level, the data associated with the next highest available level will be used instead. Otherwise, IDLgrImage renders the tile using the solid color specified by TILE_COLOR. An error is generated if any of the parameters are invalid. All units are in terms of pixels.

All image data tiles stored into the image object with SetTileData must be passed in arrays with consistent dimensions. That is, the number of channels and the interleave format must be the same for all tile data arrays. For example, if one tile is stored in an array with dimensions [3,200,340], then all other tile data arrays must have three dimensions where the first dimension value, the number of channels, is always 3. The other two dimension values, the width and height, can vary to express the tile size.

The first call to SetTileData after the object is created or after a call to DeleteTileData with the ALL keyword set determines the tile data array format to be used for all subsequent tiles. IDL generates an error if a tile data array is submitted with an inconsistent array format.

If data has already been set for the specified tile, it will be replaced by the data in the subsequent call to SetTileData.

Note

When you call IDLgrImage::SetProperty after calling SetTileData, and then draw the tiles, the image data may not be displayed. If you set an image property with SetProperty, IDL may update the image data and delete any tiles that were previously stored with the SetTileData method. If this occurs, set image properties before using SetTileData, or set image properties and then call QueryRequiredTiles to reacquire the tiles before setting and drawing the tiles.

Note

See “[Image Tiling](#)” (Chapter 4, *Object Programming*) for information creating an application that uses tiling and code examples.

Syntax

```
Obj->[IDLgrImage::]SetTileData, TileInfo, TileData [, NO_FREE=value]
```

Arguments

TileInfo

A named structure describing the tile or tiles for which the data is being set. The structures returned by the destination object's `QueryRequiredTiles` method can be passed directly (one at a time) to `SetTileData` along with the corresponding tile data.

This structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that displays the tiled <code>IDLgrImage</code> .

Table 31-9: IDLIMAGETILE Structure

If a region of the image composed of multiple tiles is being set, `X`, `Y`, `WIDTH`, and `HEIGHT` must be multiples of the tile size (unless the region extends to the edge of the image in which case `Width` and `Height` do not need to be a multiple of the tile size).

TileData

The data for the specified tile.

Keywords

NO_FREE

Set this keyword if the tile data should remain loaded for the lifetime of the `IDLgrImage`, unless explicitly deleted by the `DeleteTileData` method. If the tile cache fills up, `IDLgrImage` might automatically delete the least recently used tile data from the cache to make room for new tile data. Setting this keyword prevents the `IDLgrImage` from automatically deleting this tile data in this situation.

Version History

6.2	Introduced
-----	------------

IDLgrImage::TileDataLoaded

The IDLgrImage::TileDataLoaded function method tests whether a specified image tile has data loaded.

Syntax

Result = *Obj*->[IDLgrImage::]TileDataLoaded(*TileInfo*)

Return Value

Returns 1 (one) if the tile has data already loaded, or 0 (zero) otherwise.

Arguments

TileInfo

A named structure describing the tile to be queried. Only one tile at a time can be passed to TileDataLoaded. The structure contains the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile(s) measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile(s) measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile(s) in pixels.
HEIGHT	Long	The height of the tile(s) in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that displays the tiled IDLgrImage.

Keywords

None.

Version History

6.4	Introduced
-----	------------

IDLgrLegend

The IDLgrLegend object provides a simple interface for displaying a legend. The legend itself consists of a (filled and/or framed) box around one or more legend items (arranged in a single column) and an optional title string. Each legend item consists of a glyph patch positioned to the left of a text string. The glyph patch is drawn in a square which is a fraction of the legend label font height. The glyph itself can be in one of two types (see the TYPE keyword). In line type, the glyph is a line segment with line style, thickness and color attributes and an optional symbol object drawn over it. In fill type, the glyph is a square patch drawn with color and optional pattern object attributes.

An IDLgrLegend object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrlegend__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BORDER_GAP

A floating-point value to indicate the amount of blank space to be placed around the outside of the glyphs and text items. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height).

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLUMNS

An integer value to indicate the number of columns the legend items should be displayed in. The default is one column.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILL_COLOR

The color to be used to fill the legend background box. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [255,255,255].

Property Type	COLOR		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FONT

An object reference to an instance of an IDLgrFont object class that describes the font to use to draw the legend labels. The default is 12 point Helvetica.

Note

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a font object that will be destroyed when this legend object is destroyed, leaving a dangling object reference.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrLegend object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GAP

A floating-point value that indicates the amount of blank space to be placed vertically between each legend item. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height). The same gap is placed horizontally between the legend glyph and the legend text string.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GLYPH_WIDTH

A floating-point value to indicate the width of the glyphs, measured as a fraction of the font height. The default is 0.8 (80% of the font height).

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_COLOR

An array of colors defining the color of each item. The array defines M different colors, and should be either of the form $[3, M]$ or $[M]$. In the first case, the three values

are used as an RGB triplet, in the second case, the single value is used as a color index value. The default color is [0,0,0].

Property Type	Color array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_LINestyle

An integer array of integers defining the style of the line to be drawn if the TYPE property is set to zero. The array can be of the form $[M]$ or $[2,M]$. The first form selects the linestyle for each legend item from the predefined defaults. To use a predefined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

The second form specifies the stippling pattern explicitly for each legend item (see the LINestyle property to [IDLgrPolyline::Init](#) for details).

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_NAME

An string array representing the names of items in the legend.

Specifying this property is the same as specifying the optional *altItemNames* argument to the `IDLgrLegend::Init` method.

Property Type	String array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_OBJECT

An array of object references of type `IDLgrSymbol` or `IDLgrPattern` that represents the shapes of the items in the legend. A symbol object is drawn only if the `TYPE` property is set to zero. A pattern object is used when drawing the color patch if the `TYPE` property is set to one. The default object is the `NULL` object.

Note

If one or more `IDLgrSymbol` object references are provided, the `SIZE` property of those objects may be modified by this legend to suit its layout needs.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrLegend` object is destroyed.

Property Type	Object reference array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_THICK

A floating-point array of floating-point values that define the thickness of each item line, in points, where each element is a value between 1.0 and 10.0. Out-of-range values are quietly clamped to the allowed range. This property is only used if the `TYPE` property is set to zero. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ITEM_TYPE

An integer array that defines the type of glyph to be displayed for each item:

- 0 = line type (the default)
- 1 = filled box type

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUTLINE_COLOR

The color to be used to draw the legend outline box. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0,0,0].

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUTLINE_THICK

A floating-point value between 1.0 and 10.0 that defines the thickness of the outline frame, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARENT

An object reference to the object that contains this legend.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RECOMPUTE

A Boolean value that determines whether to recompute the legend dimensions when the legend is redrawn.

- 0 = Prevent IDL from recomputing legend dimensions (the default).
- 1 = Recompute the legend dimensions when the legend is redrawn.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: No	Registered: No

SHOW_FILL

A Boolean value that indicates whether the background should be filled with a color:

- 0 = Do not fill background (the default)
- 1 = Fill background

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHOW_OUTLINE

A Boolean value indicating whether the outline box should be displayed:

- 0 = Do not display outline (the default)
- 1 = Display outline

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXT_COLOR

The color to be used to draw the legend item text. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is [0,0,0].

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the legend. The default is the null object, specifying that no title is drawn. The title will be centered at the top of the legend, even if the text object itself has an associated location.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrLegend object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form $[xmin, xmax]$ that specifies the range of the X data coordinates covered by the legend.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the legend.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, [*s*₀, *s*₁], of scaling factors that convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of the *Z* data coordinates covered by the legend.

Note

Until the legend is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the legend object to get the data dimensions of the legend prior to a draw operation.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrLegend::Cleanup

The IDLgrLegend::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrLegend::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrLegend::ComputeDimensions

The IDLgrLegend::ComputeDimensions function method retrieves the dimensions of a legend object for the given destination object. In order to compute the effective dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a three-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the legend object measured in data units.

Syntax

```
Result = Obj->[IDLgrLegend::]ComputeDimensions( DestinationObject  
[, PATH=objref(s)] )
```

Return Value

Returns the dimensions of a legend object for the given destination object.

Arguments

DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the legend are being requested.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLegend::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

5.1	Introduced
-----	------------

IDLgrLegend::GetProperty

The IDLgrLegend::GetProperty procedure method retrieves the value of a property or group of properties for the legend.

Syntax

Obj->[IDLgrLegend::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrLegend Properties” on page 4030 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrLegend::Init

The IDLgrLegend::Init function method initializes the legend object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrLegend' [, aItemNames] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrLegend::]Init([aItemNames] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

aItemNames

An array of strings to be used as the displayed item label. The length of this array is used to determine the number of items to be displayed. Each item is defined by taking one element from the ITEM_NAME, ITEM_TYPE, ITEM_LINESTYLE, ITEM_THICK, ITEM_COLOR, and ITEM_OBJECT vectors. If the number of items (as defined by the ITEM_NAME array) exceeds any of the attribute vectors, the attribute defaults will be used for any additional items.

Note

The value specified by the *aItemNames* argument is used to initialize the value of the [ITEM_NAME](#) property of the IDLgrLegend object.

Keywords

Any property listed under “[IDLgrLegend Properties](#)” on page 4030 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrLegend:: SetProperty

The IDLgrLegend::SetProperty procedure method sets the value of a property or group of properties for the legend.

Syntax

Obj->[IDLgrLegend::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrLegend Properties](#)” on page 4030 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrLight

A light object represents a source of illumination for three-dimensional graphic objects. Lights may be either ambient, positional, directional, or spotlights. The first 8 non-ambient type lights encountered in a scene are activated. Any additional non-ambient lights are ignored. Ambient lights do not count toward the limit of 8 active lights. However, an application should define only a single ambient light since only the last ambient light encountered in a scene will be used to define the ambient light properties. If a positional, directional or spotlight type of light is not explicitly created, the default light **TYPE** is ambient. Lights are not required for objects displayed in two dimensions.

An IDLgrLight object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrLight::Init](#)” on page 4065.

ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Note

This structure returns ALPHA_CHANNEL, CLIP_PLANES, DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, and [XYZ]RANGE properties that are consistent with other graphic objects. However, these properties are not used by the IDLgrLight object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ATTENUATION

A 3-element floating-point vector of the form [constant, linear, quadratic] that describes the factor by which light intensity is to fall with respect to distance from the light source. ATTENUATION applies only to Positional and Spot lights, as specified by the TYPE property. The overall attenuation factor is computed as follows:

```
attenuation = 1/(constant + linear*distance +
quadratic*distance^2)
```

By default, the values are [1, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Attenuation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

COLOR

A three-element byte vector specifying the RGB color of the light. The default is [255, 255, 255], which is a white light. The color of a light is ignored when graphics are sent to graphics destinations using the Indexed color model, in which case light intensities are scaled into the range of colors available on the graphics destination.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CONEANGLE

A floating-point value that specifies the angle (measured in degrees) of coverage for a spotlight. The default is 60.

Property Type	FLOAT		
Name String	Spotlight cone angle		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIRECTION

A three-element floating-point vector representing the direction in which a spotlight is to be pointed. The default is [0,0,-1].

Note

For directional lights, the light's parallel rays follow a vector beginning at the position specified by LOCATION and ending at [0, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Spotlight direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FOCUS

A floating-point value that describes the attenuation of intensity for spotlights as the distance from the center of the cone of coverage increases. This factor is used as an exponent to the cosine of the angle between the direction of the spotlight and the direction from the light to the vertex being lighted. The default is 0.0.

Property Type	FLOAT		
Name String	Spotlight attenuation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or enumerated list item that indicates whether this light should be enabled:

Value	Property Sheet Value	Description
0	True	Enable light (the default)
1	False	Disable light

Note

If no lights are present in the view (or if all lights in the view are hidden), an ambient light will be provided by default.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTENSITY

A floating-point value between 0.0 (darkest) and 1.0 (brightest) that indicates the intensity of the light. The default is 1.0.

Property Type	FLOAT		
Name String	Intensity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LIGHT_INDEX

Use this property to allow a vertex shader program to identify individual light objects in a scene and to locate property information such as color or position associated with the light object. This property is only useful when the `IDLgrShader` object referenced by the `SHADER` property has a vertex shader program that does lighting calculations.

Set this property to a scalar integer between the values of -1 and 7, inclusive. If set to -1, IDL ignores this property. Otherwise, each light in a scene, up to the maximum number of 8, should have a unique index value. If any non-ambient light objects share `LIGHT_INDEX` property values, the object with a shared `LIGHT_INDEX` value encountered last in the scene deactivates all prior light objects with the same index value.

If you do not set this property, IDL automatically assigns an index value, but this value is unimportant unless you have a shader program performing lighting calculations. If your application is using a shader program, associate the light index with the OpenGL Shading Language (GLSL) light source. For example, if you set the `LIGHT_INDEX` property on an instance of a diffuse `IDLgrLight` object to the value of 3, the following GLSL shader language code retrieves the color of that light:

```
Vec4 diffuse_light_color = gl_LightSource[3].diffuse;
```

where `gl_LightSource` is a built-in GLSL uniform variable.

Note

IDL does not store ambient lights in the `gl_LightSource` table. In a GLSL shader program, retrieve the color of the IDL ambient light using uniform variable `gl_LightModelProperties.ambient`, the built-in GLSL ambient light uniform variable.

See [Chapter 14, “Lighting Shaders”](#) (*Object Programming*) for more information about accessing lights in a shader program.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LOCATION

A floating-point vector of the form $[x, y, z]$ describing the position of the light. By default, the position is $[0, 0, 0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

Note

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination’s palette for any graphics destination that uses the Indexed color model.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrLight object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass).

Note

IDLgrLight ignores this property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TYPE

An integer value or an enumerated list item that indicates the type of light. Valid values are:

Value	Property Sheet Value	Description
0	Ambient	An ambient light is a universal light source, which has no direction or position. An ambient light illuminates every surface in the scene equally, which means that no edges are made visible by contrast. Ambient lights control the overall brightness and color of the entire scene. If no value is specified for the TYPE property, an ambient light is created.
1	Positional	A positional light supplies divergent light rays, and will make the edges of surfaces visible by contrast if properly positioned. A positional light source can be located anywhere in the scene.
2	Directional	A directional light supplies parallel light rays. The effect is that of a positional light source located at an infinite distance from scene.
3	Spotlight	A spotlight illuminates only a specific area defined by the light's position, direction, and the cone angle, or angle which the spotlight covers

Property Type	ENUMLIST		
Name String	Type		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrLight::Cleanup

The IDLgrLight::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrLight:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrLight::GetCTM

The IDLgrLight::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrLight::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the light object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLight::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrLight::GetProperty

The IDLgrLight::GetProperty procedure method retrieves the value of a property or group of properties for the light.

Syntax

Obj->[IDLgrLight::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrLight Properties](#)” on page 4051 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrLight::Init

The IDLgrLight::Init function method initializes the light object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrLight' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrLight::]Init( [, PROPERTY=value]) (In a lifecycle method  
only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrLight Properties” on page 4051 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrLight:: SetProperty

The IDLgrLight::SetProperty procedure method sets the value of a property or group of properties for the light.

Syntax

Obj->[IDLgrLight::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrLight Properties” on page 4051 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrModel

A model object represents a graphical item or group of items that can be transformed (rotated, scaled, and/or translated). It serves as a container of other IDLgrModel objects or atomic graphic objects. IDLgrModel applies a transform to the current view tree.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrModel::Init](#)” on page 4086.

Properties

Objects of this class have the following properties. See “[IDLgrModel Properties](#)” on page 4070 for details on individual properties.

- [ACTIVE_POSITION](#)
- [ALL](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [LIGHTING](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RENDER_METHOD](#)
- [SELECT_TARGET](#)
- [TRANSFORM](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrModel::Add](#)
- [IDLgrModel::Cleanup](#)
- [IDLgrModel::Draw](#)
- [IDLgrModel::GetByName](#)
- [IDLgrModel::GetCTM](#)
- [IDLgrModel::GetProperty](#)
- [IDLgrModel::Init](#)
- [IDLgrModel::Reset](#)
- [IDLgrModel::Rotate](#)
- [IDLgrModel::Scale](#)
- [IDLgrModel::SetProperty](#)
- [IDLgrModel::Translate](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.2	Added ACTIVE_POSITION, RENDER_METHOD properties

See Also

[“Translating, Rotating and Scaling Objects”](#) (Chapter 3, *Object Programming*)

IDLgrModel Properties

IDLgrModel objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrModel::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrModel::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrModel::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ACTIVE_POSITION](#)
- [ALL](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [LIGHTING](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RENDER_METHOD](#)
- [SELECT_TARGET](#)
- [TRANSFORM](#)

In addition, objects of this class inherit:

- [IDL_Container](#)
- [IDLitComponent](#)

ACTIVE_POSITION

This scalar integer property is a zero-based index into the model container. It indicates the container index of the object that is drawn by this model when the value of the RENDER_METHOD property is 1.

This property is ignored when the value of the RENDER_METHOD property is not 1.

The default value of this property is 0, indicating the first object in the container.

If this property specifies an index that does not refer to a valid container index, this model object draws nothing when the value of the RENDER_METHOD property is 1. This can happen when the value of the ACTIVE_POSITION property is less than zero, or greater than or equal to the number of objects currently in the container.

This property is registered as an integer, but it is hidden by default.

Property Type	INTEGER		
Name String	Active position		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ALL

An anonymous structure containing the values of all of the properties associated with this object.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

CLIP_PLANES

An 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$.

Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Note - Clipping planes are applied in the data space of the objects this model contains (prior to the application of this model's transform).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Clipping planes		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Test Enable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Depth Write Disable		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw the model and children (the default)
1	False	Do not draw the model or children

Note

HIDE only controls the display attributes of IDLgrModel children since the IDLgrModel object itself lacks geometry.

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LIGHTING

An integer value that indicates whether lighting is to be enabled or disabled for all atomic graphic objects that have this model as a parent. IDLgrModel objects that have this model as a parent will not be effected, as they have their own value for this property. If this value is set to 0, any lights added as children of this model will be used to illuminate any other models in the view hierarchy that have lighting enabled.

- 0 = Disable lighting
- 1 = Enable single-sided lighting
- 2 = Enable double-sided lighting (the default)

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Lighting		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_METHOD

This scalar integer property specifies how this model object renders the objects in its container.

If this property is set to a value of 0, the default, the model object draws all objects in its container.

If this property is set to a value of 1, the model object draws only the object specified by the ACTIVE_POSITION property.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

See [Chapter 10, “Animating Objects”](#) (*Object Programming*) for more information on how to create animation displays when this property is set to 1.

SELECT_TARGET

A Boolean value that tags the model object as the target object to be returned when any object contained by the model is selected via the [IDLgrWindow::Select](#) method.

- 0 = Do not tag the model object as the target object (default).
- 1 = Tag the model object as the target object.

By default, an IDLgrModel object cannot be returned as the target of a SELECT operation since it contains no geometry.

This property is registered as a Boolean property, but it is hidden by default.

Property Type	Boolean		
Name String	Select target		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TRANSFORM

A 4-by-4 floating-point transformation matrix to be applied to the object. This matrix will be multiplied by its parent's transformation matrix (if the parent has one). The default is the identity matrix. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Model transform		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

IDLgrModel::Add

The IDLgrModel::Add procedure method adds a child to this Model.

Syntax

Obj->[IDLgrModel::]Add, *Object* [, /ALIAS] [, POSITION=*index*]

Arguments

Object

An instance of an atomic graphic object or another model object to be added to the model object.

Keywords

ALIAS

Set this keyword to a nonzero value to indicate that an alias—rather than the object itself—is to be added to the model. With this keyword you can add the same object to multiple models without duplicating that object and its children. If this keyword is set, the PARENT keyword on the object being added will not change. Furthermore, if this keyword is set, the object being added will not be destroyed when the model is destroyed.

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.0	Introduced
-----	------------

IDLgrModel::Cleanup

The IDLgrModel::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrModel:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrModel::Draw

The IDLgrModel::Draw procedure method draws the specified picture to the specified graphics destination. *This method is provided for purposes of sub-classing only, and is intended to be called only from the Draw method of a subclass of IDLgrModel.*

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

Obj->[IDLgrModel::]Draw, *Destination*, *Picture*

Arguments

Destination

The destination object ([IDLgrBuffer](#), [IDLgrClipboard](#), [IDLgrPrinter](#), or [IDLgrWindow](#)) to which the specified view object will be drawn.

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrModel::GetByName

The IDLgrModel::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrModel::]GetByName(*Name*)

Return Value

Returns the object reference to the named object or a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX file system. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrModel::GetCTM

The IDLgrModel::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrModel::]GetCTM( [, DESTINATION=objref]  
[ , PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the model object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrModel::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrModel::GetProperty

The IDLgrModel::GetProperty procedure method retrieves the value of a property or group of properties for the model.

Syntax

Obj->[IDLgrModel::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrModel Properties” on page 4070 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrModel::Init

The IDLgrModel::Init procedure method initializes the model object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrModel' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrModel::]Init( [, PROPERTY=value]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrModel Properties” on page 4070 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrModel::Reset

The IDLgrModel::Reset procedure method sets the current transform matrix for the model object to the identity matrix.

Note

Using this method is functionally identical to the following statement:

```
Obj->[IDLgrModel::]SetProperty, TRANSFORM=IDENTITY(4)
```

Syntax

```
Obj->[IDLgrModel::]Reset
```

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrModel::Rotate

The IDLgrModel::Rotate procedure method rotates the model about the specified axis by the specified angle. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel::]Rotate, *Axis*, *Angle* [, /PREMULTIPLY]

Arguments

Axis

A three-element vector of the form $[x, y, z]$ describing the axis about which the model is to be rotated.

Angle

The angle (measured in degrees) by which the rotation is to occur.

Keywords

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

Version History

5.0	Introduced
-----	------------

IDLgrModel::Scale

The IDLgrModel::Scale procedure method scales the model by the specified scaling factors. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel::]Scale, *Sx*, *Sy*, *Sz* [, /PREMULTIPLY]

Arguments

Sx, Sy, Sz

The floating-point scaling factors in the *x*, *y*, and *z* dimensions by which the model is to be scaled. For example, specifying a value of 0.5 for *Sx* scales the model to 50% of its original size in the *x* dimension.

Note

Because scale factors are multiplied together with the three-dimensional transformation matrix, specifying negative values for *Sx*, *Sy*, or *Sz* has the effect of reversing the corresponding axis. For example, specifying a value of -1.0 for *Sy* leaves the scale unchanged at 100%, but flips the model around the *y* axis.

Keywords

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx*, *Sy*, *Sz* to be pre-multiplied to the model's transformation matrix. By default, the scaling matrix is post-multiplied.

Example

Changing the scale factors used by the IDLgrModel object is one way to change the “zoom” of a displayed graphic.

First, we create an IDLgrWindow containing a simple plot:

```
mywindow = OBJ_NEW('IDLgrWindow', RETAIN=2)
myview = OBJ_NEW('IDLgrView', VIEWPLANE_RECT=[-10,-10,20,20])
mymodel = OBJ_NEW('IDLgrModel')
```

```
x = (FINDGEN(21) / 10.0 - 1.0) * 10.0
y = RANDOMU(seed, 21) * 10.0 - 5.0
myplot1 = OBJ_NEW('IDLgrPlot', x, y)

myview->Add, mymodel
mymodel->Add, myplot1
mywindow->Draw, myview
```

Next, change the scale of the x dimension to 80% of the current value, leaving the scale in the y and z dimensions unchanged:

```
mymodel->Scale, .8, 1.0, 1.0
mywindow->Draw, myview
```

When you have finished with the example, destroy the IDLgrWindow and IDLgrView objects:

```
OBJ_DESTROY, mywindow
OBJ_DESTROY, myview
```

Version History

5.0	Introduced
-----	------------

IDLgrModel:: SetProperty

The IDLgrModel::SetProperty procedure method sets the value of a property or group of properties for the model.

Syntax

Obj->[IDLgrModel::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrModel Properties” on page 4070 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrModel::Translate

The IDLgrModel::Translate procedure method translates the model by the specified translation offsets. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

Syntax

Obj->[IDLgrModel:]Translate, *Tx*, *Ty*, *Tz* [, /PREMULTIPLY]

Arguments

Tx, Ty, Tz

The offsets in X, Y, and Z, respectively, by which the model is to be translated.

Keywords

PREMULTIPLY

Set this keyword to cause the translation matrix specified by *Tx*, *Ty*, *Tz* to be pre-multiplied to the model's transformation matrix. By default, the translation matrix is post-multiplied.

Version History

5.0	Introduced
-----	------------

IDLgrMPEG

An IDLgrMPEG object creates an MPEG movie file from an array of image frames.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

Note

MPEG support in IDL requires a special license. For more information, contact your ITT Visual Information Solutions sales representative or technical support.

Note

The [IDLffMJPEG2000](#) object creates and reads Motion JPEG2000 (MJ2) files, and provides more functionality than the MPEG_* routines. Animations can consist of monochrome, RGB or multi-component frames that display individual components, tiles or regions. See “[Overview of Motion JPEG2000](#)” (Chapter 6, *Using IDL*) for more information.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrMPEG::Init](#)” on page 4106.

Properties

Objects of this class have the following properties. See “[IDLgrMPEG Properties](#)” on page 4097 for details on individual properties.

- [ALL](#)
- [BITRATE](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [FORMAT](#)
- [FRAME_RATE](#)

- [IFRAME_GAP](#)
- [INTERLACED](#)
- [MOTION_VEC_LENGTH](#)
- [QUALITY](#)
- [SCALE](#)
- [STATISTICS](#)
- [TEMP_DIRECTORY](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrMPEG::Cleanup](#)
- [IDLgrMPEG::GetProperty](#)
- [IDLgrMPEG::Init](#)
- [IDLgrMPEG::Put](#)
- [IDLgrMPEG::Save](#)
- [IDLgrMPEG::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

If you have a series of image objects (or simple image arrays), you can combine them into a single MPEG file using the `IDLgrMPEG` object.

```
PRO mpeg_example

    loops = 4
    increment = 32
    pulseLength = 100
    ;waitSeconds = .01

    ; Put the .MPG file into the system's /TMP directory
    filename = filepath('mpeg_example.mpg', /TMP)

    myDevice = !D.NAME
    SET_PLOT, 'z'
```

```

DEVICE, SET_RESOLUTION=[500,400]
mpegObj = OBJ_NEW('IDLgrMPEG')

FOR i = 0, increment*loops DO BEGIN
  x = 2*!PI/pulseLength * INDGEN(100) + ( i MOD increment )
  PLOT, x, SIN(x), XRANGE=[0,increment], XSTYLE=1, $
    YRANGE=[-!PI/3, !PI/3]
  mpegObj->Put, TVRD(/ORDER)
  ;WAIT, waitSeconds
ENDFOR

mpegObj -> Save, FILENAME=filename
SET_PLOT, myDevice
PRINT, 'Done writing MPEG file ' + filename
END

```

Version History

5.1	Introduced
-----	------------

IDLgrMPEG Properties

IDLgrMPEG objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrMPEG::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrMPEG::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrMPEG::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [BITRATE](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [FORMAT](#)
- [FRAME_RATE](#)
- [IFRAME_GAP](#)
- [INTERLACED](#)
- [MOTION_VEC_LENGTH](#)
- [QUALITY](#)
- [SCALE](#)
- [STATISTICS](#)
- [TEMP_DIRECTORY](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BITRATE

A double-precision floating-point value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

MPEG Version	Range
MPEG 1	0.1 to 104857200.0
MPEG 2	0.1 to 429496729200.0

Table 31-11: BITRATE Value Range

Set this property to 0.0 (the default setting) to indicate that IDL should compute the BITRATE value based upon the value you have specified for the QUALITY property. The value of BITRATE returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the BITRATE property if changing the QUALITY property value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIMENSIONS

A two-element integer array specifying the dimensions (in pixels) of each of the images to be used as frames for the movie. If this property is not specified, the dimensions of the first image loaded will be used. Once `IDLgrMPEG::Put` has been called, this property can no longer be set.

Note

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth.

FILENAME

A string that represents the name of the file in which the encoded MPEG sequence is to be stored. The default is 'idl.mpg'.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FORMAT

A Boolean value that specifies the type of MPEG encoding to use:

- 0 = MPEG1 (the default)
- 1 = MPEG2

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FRAME_RATE

An integer value that specifies the frame rate used in creating the MPEG file:

Value	Descriptions
1	23.976 frames/sec: NTSC encapsulated film rate
2	24 frames/sec: Standard international film rate
3	25 frames/sec: PAL video frame rate
4	29.97 frames/sec: NTSC video frame rate
5	30 frames/sec: NTSC drop frame video frame rate (the default)
6	50 frames/sec: Double frame rate/progressive PAL
7	59.94 frames/sec: Double frame rate NTSC
8	60 frames/sec: Double frame rate NTSC drop frame video

Table 31-12: FRAME_RATE Values

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IFRAME_GAP

A positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

Set this property to 0 (the default setting) to indicate that IDL should compute the IFRAME_GAP value based upon the value you have specified for the QUALITY property. The value of IFRAME_GAP returned by `IDLgrMPEG::GetProperty` is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

Note

Only use the IFRAME_GAP property if changing the QUALITY property value does not produce the desired results.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

INTERLACED

A Boolean value that indicates whether frames in the encoded MPEG file should be interlaced.

- 0 = Non-interlaced (the default)
- 1 = Interlaced

When interlacing is set, the video data is written to the file by writing the odd-numbered scan lines first, followed by the even-numbered scan lines. This format is used to provide smoother screen refreshing on slower display devices. You may need to generate an interlaced file if the intended playback device requires interlaced video data. Most modern MPEG playback devices can handle non-interlaced (progressive scan) video.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MOTION_VEC_LENGTH

An integer value that specifies the length of the motion vectors to be used to generate predictive frames. The following table describes the valid values:

Value	Description
1	Small motion vectors.
2	Medium motion vectors.
3	Large motion vectors.

Table 31-13: MOTION_VEC_LENGTH Values

0 (the default setting) indicates that IDL should compute the MOTION_VEC_LENGTH value based upon the value you have specified for the QUALITY property. The value of MOTION_VEC_LENGTH returned by [IDLgrMPEG::GetProperty](#) is either the value computed by IDL from the QUALITY value or the last non-zero value stored in this property.

Note

Only use the MOTION_VEC_LENGTH property if changing the QUALITY value does not produce the desired results.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

QUALITY

An integer value between 0 (low quality) and 100 (high quality), inclusive, that specifies the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

Note

Since MPEG uses JPEG (lossy) compression, the original picture quality cannot be reproduced even when setting QUALITY to its highest setting.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SCALE

A two-element floating-point vector, [*xscale*, *yscale*], indicating the scale factors to be stored with the MPEG file as hints for playback. The default is [1.0, 1.0],

indicating that the movie should be played back at the dimensions of the stored image frames.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STATISTICS

A Boolean value that determines whether to save statistical information about MPEG encoding for the supplied image frames in a file when the `IDLgrMPEG::Save` method is called. The information will be saved in a file with a name that matches that specified by the `FILENAME` property, with the extension “.stat”.

- 0 = Statistics are not saved (the default).
- 1 = Save statistics.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEMP_DIRECTORY

A string value that specifies the directory in which to place temporary files while creating the MPEG movie file. The default value is platform specific.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrMPEG::Cleanup

The IDLgrMPEG::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrMPEG::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrMPEG::GetProperty

The IDLgrMPEG::GetProperty procedure method retrieves the value of a property or group of properties for the MPEG object.

Syntax

Obj->[IDLgrMPEG::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrMPEG Properties” on page 4097 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrMPEG::Init

The IDLgrMPEG::Init function method initializes the MPEG object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Note

MPEG support in IDL requires a special license. For more information, contact your ITT Visual Information Solutions sales representative or technical support.

Syntax

```
Obj = OBJ_NEW('IDLgrMPEG' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrMPEG::]Init( [, PROPERTY=value])    (In a lifecycle method  
only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLgrMPEG Properties”](#) on page 4097 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrMPEG::Put

The IDLgrMPEG::Put procedure method puts a given image into the MPEG sequence at the specified frame. Note that all images in a given MPEG movie must have matching dimensions. If no dimensions were explicitly specified when the MPEG object was initialized, the dimensions will be set according to the dimensions of the first image.

Syntax

Obj->[IDLgrMPEG:]Put, *Image*[, *Frame*]

Arguments

Image

An instance of an IDLgrImage object or a $m \times n$ or $3 \times m \times n$ array representing the image to be loaded at the given frame.

Frame

An integer specifying the index of the frame at which the image is to be added. Frame indices start at zero. If *Frame* is not supplied, the frame number used will be one more than the last frame that was put. Frame number need not be consecutive; in case of a gap in frame numbers, the frame before the gap is repeated to fill the space.

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrMPEG::Save

The IDLgrMPEG::Save procedure method encodes and saves the MPEG sequence to the specified filename.

Note

The MPEG standard does not allow movies with odd numbers of pixels to be created.

Syntax

```
Obj->[IDLgrMPEG::]Save [, FILENAME=string]
```

Arguments

None

Keywords

FILENAME

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is `idl.mpg`.

Version History

5.1	Introduced
Pre 6.1	Deprecated CREATOR_TYPE keyword

For more information on deprecated features, see [Appendix I, “IDL API History”](#).

IDLgrMPEG:: SetProperty

The IDLgrMPEG::SetProperty procedure method sets the value of a property or group of properties for the MPEG object.

Syntax

Obj->[IDLgrMPEG::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrMPEG Properties” on page 4097 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrPalette

A palette object represents a color lookup table that maps indices to red, green, and blue values.

Superclasses

None

Creation

See “[IDLgrPalette::Init](#)” on page 4127.

Properties

Objects of this class have the following properties. See “[IDLgrPalette Properties](#)” on page 4120 for details on individual properties.

- [ALL](#)
- [BLUE_VALUES](#)
- [BOTTOM_STRETCH](#)
- [GAMMA](#)
- [GREEN_VALUES](#)
- [NAME](#)
- [N_COLORS](#)
- [RED_VALUES](#)
- [TOP_STRETCH](#)
- [UVALUE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has this following methods:

- [IDLgrPalette::Cleanup](#)
- [IDLgrPalette::GetRGB](#)

- [IDLgrPalette::GetProperty](#)
- [IDLgrPalette::Init](#)
- [IDLgrPalette::LoadCT](#)
- [IDLgrPalette::NearestColor](#)
- [IDLgrPalette::SetRGB](#)
- [IDLgrPalette::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

This section contains the following examples:

- [“Displaying Indexed Images with Object Graphics”](#) on page 4112 — accesses the palette associated with an indexed image and passes the palette data to an `IDLgrPalette` object
- [“Highlighting Features with Color in Object Graphics”](#) on page 4115 — loads a pre-defined color table into a palette object and then modifies this color table to highlight image features

Displaying Indexed Images with Object Graphics

An indexed image contains up to 256 colors, typically defined by a color table associated with the image. The value of each pixel relates to a color within the associated color table. Combinations of the primary colors (red, green, and blue) make up the colors within the color table. Most indexed images are stored as byte and therefore do not require scaling prior to display.

The following example imports an indexed image from the `avhrr.png` image file. This indexed image is a satellite photograph of the world. Complete the following steps for a detailed description of the process.

Example Code

See `displayindexedimage_object.pro` in the `examples/doc/objects` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `displayindexedimage` at the IDL command prompt or view the file in an IDL Editor window by entering `displayindexedimage.pro`.

1. Determine the path to the `avhrr.png` file:

```
file = FILEPATH('avhrr.png', $
SUBDIRECTORY = ['examples', 'data'])
```

- Use [QUERY_IMAGE](#) to query the file to determine image parameters:

```
queryStatus = QUERY_IMAGE(file, imageInfo)
```

- Output the results of the file query:

```
PRINT, 'Query Status = ', queryStatus
HELP, imageInfo, /STRUCTURE
```

The following text appears in the Output Log:

```
Query Status =          1
** Structure <141d0b0>, 7 tags, length=36, refs=1:
CHANNELS          LONG          1
DIMENSIONS        LONG          Array[2]
HAS_PALETTE       INT           1
IMAGE_INDEX       LONG          0
NUM_IMAGES        LONG          1
PIXEL_TYPE        INT           1
TYPE              STRING        'PNG'
```

- Set the image size parameter from the query information:

```
imageSize = imageInfo.dimensions
```

The HAS_PALETTE tag has a value of 1. Thus, the image has a palette (color table), which is also contained within the file. The color table is made up of its three primary components (the red component, the green component, and the blue component).

- Use [READ_IMAGE](#) to import the image and its associated color table from the file:

```
image = READ_IMAGE(file, red, green, blue)
```

- Initialize the display objects:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
DIMENSIONS = imageSize, TITLE = 'An Indexed Image')
oView = OBJ_NEW('IDLgrView', $
VIEWPLANE_RECT = [0., 0., imageSize])
oModel = OBJ_NEW('IDLgrModel')
```

- Initialize the image's palette object:

```
oPalette = OBJ_NEW('IDLgrPalette', red, green, blue)
```

- Initialize the image object with the resulting palette object:

```
oImage = OBJ_NEW('IDLgrImage', image, $
PALETTE = oPalette)
```

9. Add the image object to the model, which is added to the view, then display the view in the window:

```
oModel -> Add, oImage
oView -> Add, oModel
oWindow -> Draw, oView
```

10. Use the colorbar object to display the associated color table in another window:

```
oCbWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [256, 48], $
    TITLE = 'Original Color Table')
oCbView = OBJ_NEW('IDLgrView', $
    VIEWPLANE_RECT = [0., 0., 256., 48.])
oCbModel = OBJ_NEW('IDLgrModel')
oColorbar = OBJ_NEW('IDLgrColorbar', PALETTE = oPalette, $
    DIMENSIONS = [256, 16], SHOW_AXIS = 1)
oCbModel -> Add, oColorbar
oCbView -> Add, oCbModel
oCbWindow -> Draw, oCbView
```

The following figure shows the resulting indexed image and its color table.

Figure 31-4: Indexed Image and Associated Color Table in Object Graphics

The data values within the image are indexed to specific colors within the table. You can change the color table associated with this image to show how an indexed image is dependent upon its related color tables.

11. Change the palette (color table) to the EOS B pre-defined color table:

```
oPalette -> LoadCT, 27
```

12. Redisplay the image in another window to show the palette change:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = imageSize, TITLE = 'An Indexed Image')
oWindow -> Draw, oView
```

13. Redisplay the colorbar in another window to show the palette change:

```
oCbWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [256, 48], $
    TITLE = 'EOS B Color Table')
oCbWindow -> Draw, oCbView
```

The following figure shows the indexed image with the EOS B color table.

Figure 31-5: Indexed Image and EOS B Color Table in Object Graphics

14. Clean up the object references. When working with objects always remember to clean up any object references with the OBJ_DESTROY routine. Since the view contains all the other objects, except for the window (which is destroyed by the user), you only need to use OBJ_DESTROY on the view object.

```
OBJ_DESTROY, [oView, oCbView, oPalette]
```

Highlighting Features with Color in Object Graphics

This example shows how to create a color table to highlight image features using Object Graphics. Complete the following steps for a detailed description of the process.

Example Code

See `highlightfeatures_object.pro` in the `examples/doc/objects` subdirectory of the IDL installation directory for code that duplicates this example. Run the example procedure by entering `highlightfeatures_object` at the IDL command prompt or view the file in an IDL Editor window by entering `highlightfeatures_object.pro`.

1. Determine the path to the `mineral.png` file:

```
mineralFile = FILEPATH('mineral.png', $
    SUBDIRECTORY = ['examples', 'data'])
```

2. Import the image and its associated color table into IDL:

```
mineralImage = READ_PNG(mineralFile, red, green, blue)
```

3. Determine the size of the imported image:

```
mineralSize = SIZE(mineralImage, /DIMENSIONS)
```

4. Initialize objects necessary for a graphics display:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [mineralSize[0], mineralSize[1]], $
    TITLE = 'mineral.png')
oView = OBJ_NEW('IDLgrView', VIEWPLANE_RECT = [0., 0., $
    mineralSize[0], mineralSize[1]])
oModel = OBJ_NEW('IDLgrModel')
```

5. Initialize a palette object containing the image's associated color table and apply the palette to the image objects:

```
oPalette = OBJ_NEW('IDLgrPalette', red, green, blue)
oImage = OBJ_NEW('IDLgrImage', mineralImage, $
    PALETTE = oPalette)
```

The objects are then added to the view, which is displayed in the window.

6. Add the image to the model, then add the model to the view:

```
oModel -> Add, oImage
oView -> Add, oModel
```

Draw the view in the window:

```
oWindow -> Draw, oView
```

This scanning electron microscope image shows mineral deposits in a sample of polished granite and gneiss. The associated color table is a reverse grayscale.

The following figure shows that the associated color table highlights the gneiss very well, but the other features are not very clear. The other features can be defined with IDL's pre-defined color table, RAINBOW.

Figure 31-6: Mineral Image and Default Color Table (Object Graphics)

The palette can easily be modified to show the RAINBOW pre-defined color table in another instance of the window object.

7. Update palette with RAINBOW color table and then display the image with this color table in another instance window of the window object:

```
oPalette -> LoadCT, 13
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
    DIMENSIONS = [mineralSize[0], mineralSize[1]], $
    TITLE = 'RAINBOW Color')
oWindow -> Draw, oView
```

The following figure shows that the yellow, cyan, and red sections are now apparent, but the cracks are no longer visible. Details within the yellow areas

and the green background are also difficult to distinguish. These features can be highlighted by designing your own color table.

Figure 31-7: Mineral Image and RAINBOW Color Table (Object Graphics)

The features within the image are at specific ranges in between 0 and 255. Instead of a progressive color table, specific colors can be defined to be constant over these ranges. Any contrasting colors can be used, but the easiest to derive are the additive and subtractive primary colors used in the previous section.

8. Define colors for a new color table:

```
colorLevel = [[0, 0, 0], $ ; black
              [255, 0, 0], $ ; red
              [255, 255, 0], $ ; yellow
              [0, 255, 0], $ ; green
              [0, 255, 255], $ ; cyan
              [0, 0, 255], $ ; blue
              [255, 0, 255], $ ; magenta
              [255, 255, 255]] ; white
```

9. Create a new color table that contains eight levels, including the highest end boundary by first deriving levels for each color in the new color table:

```
numberOfLevels = CEIL(!D.TABLE_SIZE/8.)
level = INDGEN(!D.TABLE_SIZE)/numberOfLevels
```

10. Place each color level into its appropriate range.

```
newRed = colorLevel[0, level]
newGreen = colorLevel[1, level]
newBlue = colorLevel[2, level]
```

11. Include the last color in the last level:

```
newRed[!D.TABLE_SIZE - 1] = 255
```

```
newGreen[!D.TABLE_SIZE - 1] = 255
newBlue[!D.TABLE_SIZE - 1] = 255
```

12. Apply the new color table to the palette object:

```
oPalette -> SetProperty, RED_VALUES = newRed, $
          GREEN_VALUES = newGreen, BLUE_VALUES = newBlue
```

13. Display the image with this color table in another window:

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
                  DIMENSIONS = [mineralSize[0], mineralSize[1]], $
                  TITLE = 'Cube Corner Colors')
oWindow -> Draw, oView
```

The following figure shows that each image feature is readily distinguishable.

Figure 31-8: Mineral Image and Derived Color Table (Object Graphics)

14. Clean up object references. When working with objects always remember to clean up any object references with the OBJ_DESTROY routine. Since the view contains all the other objects, except for the window (which is destroyed by the user), you only need to use OBJ_DESTROY on the view and the palette object:

```
OBJ_DESTROY, [oView, oPalette]
```

Version History

5.0	Introduced
6.2	Added UVALE and NAME properties

IDLgrPalette Properties

IDLgrPalette objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPalette::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPalette::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPalette::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [BLUE_VALUES](#)
- [BOTTOM_STRETCH](#)
- [GAMMA](#)
- [GREEN_VALUES](#)
- [NAME](#)
- [N_COLORS](#)
- [RED_VALUES](#)
- [TOP_STRETCH](#)
- [UVALUE](#)

ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the `IDLgrPalette::Init` method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

BOTTOM_STRETCH

An integer value in the range of $0 \leq \textit{Value} \leq 100$ to indicate what percentage of the palette entries at the bottom of the palette should be filled with the value of the first palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at this entry and ending at the entry specified by the value of the `TOP_STRETCH` property. The default is 0 (zero).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GAMMA

A floating-point value that indicates the gamma value to be applied to the color palette. This value should be in the range of $0.1 \leq \textit{Gamma} \leq 10.0$. The default is 1.0.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the [IDLgrPalette::Init](#) method.

Property Type	Byte-vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that determines the number of elements in the color palette.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RED_VALUES

A byte vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the [IDLgrPalette::Init](#) method.

Property Type	Byte vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TOP_STRETCH

A floating-point value in the range of $0 \leq \textit{Value} \leq 100$ to indicate what percentage of the palette entries at the top of the palette should be filled with the value of the last palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at the entry specified by the value of the `BOTTOM_STRETCH` property and ending at this entry. The default is 0 (zero).

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the `UVALUE` property are *not* automatically cleaned up when the `IDLgrPalette` object is destroyed.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPalette::Cleanup

The IDLgrPalette::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPalette:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPalette::GetRGB

The IDLgrPalette::GetRGB function method returns the RGB values contained in the palette at the given index. The returned value is a three-element vector of the form [red, green, blue].

Syntax

Result = *Obj*->[IDLgrPalette::]GetRGB(*Index*)

Return Value

Returns the RGB values contained in the palette at the given index.

Arguments

Index

The index whose RGB values are desired. This value should be in the range of $0 \leq \textit{Index} < \textit{N_COLORS}$, where *N_COLORS* is the number of elements in the color palette, as returned by the *N_COLORS* keyword to the IDLgrPalette:GetProperty method.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPalette::GetProperty

The IDLgrPalette::GetProperty procedure method retrieves the value of a property or group of properties for the palette.

Syntax

Obj->[IDLgrPalette::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 4120 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrPalette::Init

The IDLgrPalette::Init function method initializes a palette object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPalette', aRed, aGreen, aBlue [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPalette::]Init([aRed, aGreen, aBlue] [, PROPERTY=value])  
(In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *aRed*, *aGreen*, and *aBlue* arguments are used to initialize the value of the [RED_VALUES](#), [GREEN_VALUES](#), and [BLUE_VALUES](#), properties of the IDLgrPalette object.

aRed

A vector containing the red values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aRed* vector must not exceed 256.

aGreen

A vector containing the green values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aGreen* vector must not exceed 256.

aBlue

A vector containing the blue values for the color palette. These values should be within the range of $0 \leq \text{Value} \leq 255$. The number of elements comprising the *aBlue* vector must not exceed 256.

Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 4120 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrPalette::LoadCT

The IDLgrPalette::LoadCT procedure method loads one of the IDL predefined color tables into an IDLgrPalette object.

Syntax

Obj->[IDLgrPalette::]LoadCT, *TableNum* [, FILE=*colortable filename*]

Arguments

TableNum

The number of the pre-defined IDL color table to load, from 0 to 40.

Keywords

FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl` in the IDL distribution. The `MODIFYCT` procedure can be used to create and modify colortable files.

Version History

5.0	Introduced
-----	------------

IDLgrPalette::NearestColor

The IDLgrPalette::NearestColor function method returns the index of the color in the palette that best matches the given RGB values.

Syntax

Result = *Obj*->[IDLgrPalette::]NearestColor(*Red*, *Green*, *Blue*)

Return Value

Returns the index of the color in the palette that best matches the given RGB values.

Arguments

Red

The red value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Green

The green value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Blue

The blue value of the color that should be matched. This value should be within the range of $0 \leq \text{Value} \leq 255$.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPalette::SetRGB

The IDLgrPalette::SetRGB procedure method sets the color values at a specified index in the palette to the specified Red, Green and Blue values.

Syntax

Obj->[IDLgrPalette::]SetRGB, *Index*, *Red*, *Green*, *Blue*

Arguments

Index

The index within the Palette object to be set. This value should be in the range of $0 \leq \textit{Value} < \textit{N_COLORS}$.

Red

The red value to set in the color palette.

Green

The green value to set in the color palette.

Blue

The blue value to set in the color palette.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPalette:: SetProperty

The IDLgrPalette::SetProperty procedure method sets the value of a property or group of properties for the palette.

Syntax

Obj->[IDLgrPalette::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPalette Properties](#)” on page 4120 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrPattern

A pattern object describes which pixels are filled and which are left blank when an area is filled. Pattern objects are used by setting the FILL_PATTERN property of a polygon object equal to the object reference of the pattern object.

Superclasses

None

Creation

See [“IDLgrPattern::Init”](#) on page 4141.

Properties

Objects of this class have the following properties. See [“IDLgrPattern Properties”](#) on page 4135 for details on individual properties.

- [ALL](#)
- [NAME](#)
- [ORIENTATION](#)
- [PATTERN](#)
- [SPACING](#)
- [STYLE](#)
- [THICK](#)
- [UVALUE](#)

Methods

This class has this following methods:

- [IDLgrPattern::Cleanup](#)
- [IDLgrPattern::GetProperty](#)
- [IDLgrPattern::Init](#)
- [IDLgrPattern::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.2	Added UVALUE and NAME properties

IDLgrPattern Properties

IDLgrPattern objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPattern::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPattern::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPattern::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [NAME](#)
- [ORIENTATION](#)
- [PATTERN](#)
- [SPACING](#)
- [STYLE](#)
- [THICK](#)
- [UVALUE](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ORIENTATION

An integer representing the angle (measured in degrees counterclockwise from the horizontal) of the lines used in a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to one.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PATTERN

A 32 x 32 bit array (bitmap) describing the pattern that will be tiled over a polygon when a pattern fill is used. The bitmap must be configured as a 4 x 32 “bitmap byte array” as created by the CVTTOBM function. Each bit that is a 1 is drawn, each bit that is 0 is not drawn. Each bit in this array represents a 1 point by 1 point square area of pixels on the destination device. This property is ignored unless the *Style* argument (or STYLE property) is set to 2.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SPACING

A floating-point value representing the distance (measured in points) between the lines used for a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to 1. The default is 2.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STYLE

An integer value that specifies the type of pattern, as follows:

- 0 = Solid (default)
- 1 = Line Fill
- 2 = Pattern

Specifying this property is the same as specifying the optional *Style* argument to the [IDLgrPattern::Init](#) method.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0 that specifies the line thickness to be used to draw the pattern lines for a Line Fill, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points. This property is ignored unless the *Style* argument or STYLE property is set to 1.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrPattern object is destroyed.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPattern::Cleanup

The IDLgrPattern::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPattern::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPattern::GetProperty

The IDLgrPattern::GetProperty procedure method retrieves the value of a property or group of properties for the pattern.

Syntax

Obj->[IDLgrPattern::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 4135 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.0	Introduced
-----	------------

IDLgrPattern::Init

The IDLgrPattern::Init function method initializes the pattern object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPattern' [, *Style*] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrPattern::]Init([*Style*] [, *PROPERTY=value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Style

A integer value representing the type of pattern. Valid values are:

- 0 = Solid color (default)
- 1 = Line Fill
- 2 = Pattern

Note

The value specified by the *Style* argument is used to initialize the value of the **STYLE** property of the IDLgrPattern object.

Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 4135 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrPattern:: SetProperty

The IDLgrPattern::SetProperty procedure method sets the value of a property or group of properties for the pattern.

Syntax

Obj->[IDLgrPattern::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLgrPattern Properties](#)” on page 4135 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrPlot

A plot object creates a set of polylines connecting data points in two-dimensional space.

An IDLgrPlot object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Note

See [IDLgrAxis](#) for information on configuring plot axes.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrPlot::Init](#)” on page 4169.

Properties

Objects of this class have the following properties. See “[IDLgrPlot Properties](#)” on page 4146 for details on individual properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [DATA](#)
- [DATAY](#)
- [DEPTH_TEST_FUNCTION](#)
- [DOUBLE](#)
- [HISTOGRAM](#)
- [MAX_VALUE](#)
- [NSUM](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [ALPHA_CHANNEL](#)
- [COLOR](#)
- [DATA_X](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [MIN_VALUE](#)
- [PALETTE](#)
- [POLAR](#)
- [RESET_DATA](#)

- [SHADER](#)
- [SYMBOL](#)
- [USE_ZVALUE](#)
- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)
- [ZVALUE](#)
- [SHARE_DATA](#)
- [THICK](#)
- [VERT_COLORS](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrPlot::Cleanup](#)
- [IDLgrPlot::GetCTM](#)
- [IDLgrPlot::GetProperty](#)
- [IDLgrPlot::GetVertexAttributeData](#)
- [IDLgrPlot::Init](#)
- [IDLgrPlot::SetProperty](#)
- [IDLgrPlot::SetVertexAttributeData](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property Added GetVertexAttributeData, SetVertexAttributeData methods

IDLgrPlot Properties

IDLgrPlot objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLgrPlot::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLgrPlot::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLgrPlot::SetProperty`.

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties. See “[IDLgrPlot Properties](#)” on page 4146 for details on individual properties.

- `ALL`
- `ALPHA_CHANNEL`
- `CLIP_PLANES`
- `COLOR`
- `DATA`
- `DATAX`
- `DATAY`
- `DEPTH_TEST_DISABLE`
- `DEPTH_TEST_FUNCTION`
- `DEPTH_WRITE_DISABLE`
- `DOUBLE`
- `HIDE`
- `HISTOGRAM`
- `LINestyle`
- `MAX_VALUE`
- `MIN_VALUE`
- `NSUM`
- `PALETTE`
- `PARENT`
- `POLAR`
- `REGISTER_PROPERTIES`
- `RESET_DATA`
- `SHADER`
- `SHARE_DATA`
- `SYMBOL`
- `THICK`
- `USE_ZVALUE`
- `VERT_COLORS`
- `XCOORD_CONV`
- `XRANGE`
- `YCOORD_CONV`
- `YRANGE`

- [ZCOORD_CONV](#)
- [ZVALUE](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the plot. The default value of 1.0 causes IDL to draw the plot completely opaque. If the value of this property is less than 1.0, then the pixels of the plot are blended with the pixels already on the screen, where the color of the plot is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha. Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode. If 3-channel (RGB) `VERT_COLORS` are supplied, then the value of this property is used for the alpha at each vertex when drawing the plot line. If 4-channel (RGBA) `VERT_COLORS` are supplied, then the alpha from each vertex color is used for the alpha at each vertex when drawing the plot line.

When a plot is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless `VERT_COLORS` are supplied. If the `VERT_COLORS` are RGB, then the alpha value of the symbol is used to draw the

symbol. If the VERT_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this plot. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

The plot data of any type in a $3 \times n$ array, [*DataX*, *DataY*, *DataZ*].

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DATA X

A vector of any type that specifies the X values to be plotted.

Specifying this property is the same as specifying the optional *X* argument to the [IDLgrPlot::Init](#) method

Property Type	Vector of any type		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAY

A vector of any type that specifies the Y values to be plotted.

Specifying this property is the same as specifying the optional *X* argument to the `IDLgrPlot::Init` method.

Property Type	Vector of any type		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object’s depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test

passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HISTOGRAM

A Boolean value that determines whether to use only horizontal and vertical lines to connect the plotted points.

- 0 = The points are connected using a single straight line (the default).
- 1 = Use only horizontal and vertical lines to connect the plotted points.

Property Type	Boolean		
Name String	Histogram plot		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer value that indicates the line style to be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted

2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. When this property is set, data values greater than the value of `MAX_VALUE` are treated as missing data and are not plotted. Note that the IEEE

floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NSUM

An integer value representing the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

Property Type	Integer		
Name String	Points to average		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPlot object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

POLAR

A Boolean value that determines whether to create a polar plot. The *X* and *Y* arguments must both be present. The *X* argument represents the radius, and the *Y* argument represents the angle expressed in radians.

Property Type	Boolean		
Name String	Polar plot		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XY] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via a DATA property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the plot is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional plot objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHARE_DATA

An object reference to an object with which data is to be shared by this plot. A plot may only share data with another plot. The SHARE_DATA property is intended for

use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPlot object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference vector containing instances of the [IDLgrSymbol](#) object class. Each symbol in the vector will be drawn at the corresponding plotted point. If there are more points than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a plot, set the SYMBOL property equal to a null object reference.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPlot object is destroyed.

Property Type	Object reference vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_ZVALUE

A Boolean value that determines whether to use the current ZVALUE. The plot is considered three-dimensional if this property is set.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

VERT_COLORS

A vector of colors to be used to specify the color of the plot segment between each vertex. The vector may be of the form [n] where each entry is a color index, or of the form [3,n] where each 3-element row is an RGB color, or of the form [4,n] where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire plot is drawn in the single color provided by the COLOR property, which is the default action.

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

When VERT_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ specifying the range of x data coordinates covered by the graphic object. The plot line is *clipped* to the XRANGE values specified, but data points that lie outside the specified range are not removed. (Set the [MAX_VALUE](#) and [MIN_VALUE](#) properties if data outside the range should be removed.) If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ specifying the range of y data values covered by the graphic object. The plot line is *clipped* to the YRANGE values specified, but data points that lie outside the specified range are not removed. (Set the [MAX_VALUE](#) and [MIN_VALUE](#) properties if data outside the range should be removed.) If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] specifying the range of *z* data values covered by the graphic object. The plot line is *clipped* to the ZRANGE values specified, but data points that lie outside the specified range are not removed. (Set the [MAX_VALUE](#) and [MIN_VALUE](#) properties if data outside the range should be removed.) IDL maintains and returns this property in double-precision floating-point.

Note

The XRANGE and YRANGE properties can also be retrieved via the GetProperty method; ZRANGE, however, can only be retrieved, not initialized (Init method) or set (SetProperty method).

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZVALUE

A floating-point value to be used as the Z coordinate for the entire plot. By default, 0.0 is used as the Z coordinate.

Note

The USE_ZVALUE property needs to be set in order for ZVALUE to take effect.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPlot::Cleanup

The IDLgrPlot::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPlot:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPlot::GetCTM

The IDLgrPlot::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrPlot::]GetCTM( [, DESTINATION=objref] [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the plot object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPlot::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrPlot::GetProperty

The IDLgrPlot::GetProperty procedure method retrieves the value of the property or group of properties for the plot.

Syntax

Obj->[IDLgrPlot:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrPlot Properties” on page 4146 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrPlot::GetVertexAttributeData

The `IDLgrPlot::GetVertexAttributeData` procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*) for more information. This method is useful when a shader program defined by an `IDLgrShader` object modifies the vertices of an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

Obj->[`IDLgrPlot::`]GetVertexAttributeData, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the plot object using `SetVertexAttributeData`, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using `IDLgrPlot::SetVertexAttributeData`.

Keywords

None

Examples

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*).

Version History

6.4	Introduced
-----	------------

See Also

[IDLgrPlot::SetVertexAttributeData](#)

IDLgrPlot::Init

The IDLgrPlot::Init function method initializes the plot object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrPlot' [, [X,] Y] [, PROPERTY=value])

or

Result = *Obj*->[IDLgrPlot::]Init([[X,] Y] [, PROPERTY=value]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *X* and *Y* arguments are used to initialize the values of the [DATA_X](#) and [DATA_Y](#) properties of the IDLgrPlot object.

X

A vector representing the abscissa values to be plotted. If *X* is provided, *Y* is plotted as a function of *X*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the input value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

Y

The ordinate data to be plotted. The value for this argument is double-precision floating-point if the `DOUBLE` keyword is set or the input value is of type `DOUBLE`. Otherwise it is converted to single-precision floating-point.

Keywords

Any property listed under “[IDLgrPlot Properties](#)” on page 4146 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrPlot:: SetProperty

The IDLgrPlot::SetProperty procedure method sets the value of the property or group of properties for the plot.

Syntax

Obj->[IDLgrPlot::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrPlot Properties” on page 4146 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrPlot::SetVertexAttributeData

The `IDLgrPlot::SetVertexAttributeData` procedure method passes a set of per-vertex attribute data to a vertex shader program. When an `IDLgrShader` object is associated with the plot via the `SHADER` property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the plot. If there are more vertices in the plot than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, “[Advanced Rendering Using Shader Objects](#)” (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this plot object the first time this method is called. When `SetVertexAttributeData` is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type `float`, `vec2`, `vec3`, `vec4`, `mat2`, `mat3`, or `mat4`. Internally, the `mat2` type is treated as two `vec2` attribute variables, `mat3` as three `vec3` attribute variables, and `mat4` as four `vec4` attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an *x*-offset and a *y*-offset for each vertex. The vertex program defines an attribute variable using a `vec4` type so that it can be used in 4x4 general transformations. The IDL program stores the *x*- and *y*-offset information in a `[2, n]` array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the `vec4` attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use `IDLgrWindow::GetDeviceInfo` to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrPlot::]SetVertexAttributeData, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form $[n]$, $[a,n]$, or $[a,a,n]$ where a is 1,2,3, or 4 and n is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (*STYLE=0*) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.  
oPolygon->SetProperty, DATA=vertices
```

```

; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN ;; time samples
    oShader->SetUniformVariable, 'time', t
    oWindow->Draw
ENDFOR

```

And the interesting parts of the vertex shader program are:

```

attribute vec3 velocity;
uniform float time;
void main () {
    vec4 vert;
    vert = gl_Vertex + vec4(velocity * time, 0.0);
    gl_Position = gl_ModelViewProjectMatrix * vert;
}

```

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*) for more information and examples.

IDLgrPolygon

A polygon object represents one or more polygons that share a given set of vertices and rendering attributes. All polygons must be convex—that is, a line connecting any pair of vertices on the polygon cannot fall outside the polygon. Concave polygons can be converted to a set of convex polygons using the [IDLgrTessellator](#) object.

An IDLgrPolygon object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrPolygon::Init](#)” on page 4210.

Properties

Objects of this class have the following properties. See “[IDLgrPolygon Properties](#)” on page 4178 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrPolygon::Cleanup
- IDLgrPolygon::GetCTM
- IDLgrPolygon::GetMultiTextureCoord
- IDLgrPolygon::GetProperty
- IDLgrPolygon::GetVertexAttributeData
- IDLgrPolygon::Init
- IDLgrPolygon::SetMultiTextureCoord
- IDLgrPolygon::SetProperty
- IDLgrPolygon::SetVertexAttributeData

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties
6.4	Added the SHADER property Added GetVertexAttributeData, SetVertexAttributeData, GetMultiTextureCoord, and SetMultiTextureCoord methods

IDLgrPolygon Properties

IDLgrPolygon objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPolygon::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPolygon::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPolygon::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DEPTH_OFFSET](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the polygon. The default value of 1.0 causes IDL to draw the polygon completely opaque. If the value of this property is less than 1.0, then the pixels of the polygon are blended with the pixels already on the screen. The color of the polygon is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polygon object may contain many polygons, the ordering of the polygons within the object (POLYGONS property) must be considered as well.

This property has no effect on devices using indexed color mode.

If [VERT_COLORS](#) are supplied, then the value of this property is used for the vertex color alpha if the [VERT_COLORS](#) do not contain alpha values (3-channel RGB

colors). If the VERT_COLORS do contain alpha values (4-channel RGBA colors), then the alpha for each vertex color is used.

When used with textures, the ALPHA_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA_CHANNEL property).

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AMBIENT

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Ambient reflective color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BOTTOM

A scalar or three-element vector [*red*, *green*, *blue*] specifying the color used for drawing the backs of the polygons. (The back of a polygon is the side opposite the normal direction). Set this property to a scalar to draw the backs of the polygons with the same color as the front. If set to a scalar, IDL returns the default value of -1 if the property is retrieved with GetProperty. Setting a bottom color is only supported when the destination device uses RGB color mode.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Bottom color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polygons. The default color is $[0, 0, 0]$ (black). If the TEXTURE_MAP property is used, the final color is modulated by the texture map pixel values. This property is ignored if the VERT_COLORS property is provided.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

A 2-by- n or a 3-by- n array of any type which defines, respectively, the 2-D or 3-D vertex data. This property is stored as double precision floating point values if the property variable is of type DOUBLE or if the DOUBLE property parameter is also specified, otherwise it is converted to single precision floating point.

Specifying this property is the same as specifying the optional X, Y, and Z arguments to the [IDLGrPolygon::Init](#) method.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

Use this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may

produce better results on one machine than on another. Using IDL's software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

Note

DEPTH_OFFSET has no effect unless the value of the STYLE property is 2 (Filled).

Property Type	Integer		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the DEPTH_TEST_FUNCTION and DEPTH_WRITE_DISABLE properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIFFUSE

Set this property to a three-element vector [*red, green, blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Diffuse reflective color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

EMISSION

Set this property to a three-element vector [*red, green, blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Emissive color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL_PATTERN

An object reference to an IDLgrPattern object (or an array of IDLgrPattern objects) that specifies the fill pattern to use for filling the polygons. By default, FILL_PATTERN is set to a null object reference, specifying a solid fill.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPolygon object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

Property Type	Boolean		
Name String	Remove hidden		
Get: No	Set: Nos	Init: Yes	Registered: Yes

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer value that indicates the line style that should be used to draw the polygon. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

NORMALS

A 3-by-*n* floating-point array of unit polygon normals at each vertex. If this property is not set, vertex normals are computed by averaging shared polygon normals at each vertex. Normals are computed using the Right Hand Rule; that is, if the polygon is

facing the viewer, vertices are taken in counterclockwise order. To remove previously specified normals, set `NORMALS` to a scalar.

Note

Computing normals is a computationally expensive operation. Rendering speed increases significantly if you supply the surface normals explicitly. You can compute the array of polygon normals used by this property automatically. See “`COMPUTE_MESH_NORMALS`” on page 348 for details.

Once you use the `NORMALS` property in a call to `IDLgrPolygon::Init` or `IDLgrPolygon::SetProperty`, you are responsible for that `IDLgrPolygon`'s normals from then on. IDL will not calculate that `IDLgrPolygon`'s normals for you automatically, even if you draw the `IDLgrPolygon` after vertices or connectivity have been changed.

If you do not use the `NORMALS` property, IDL calculates normals the first time it draws the `IDLgrPolygon`. IDL reuses those normals for subsequent draws unless it determines that a fresh recalculation of normals is required, such as if the vertices of the `IDLgrPolygon` are changed, or you supply new normals via the `NORMALS` property.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

An object reference to a palette object (an instance of the `IDLgrPalette` object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the `PALETTE` property on this object is not set, the destination object `PALETTE` property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrPolygon` object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: No	Set: No	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

POLYGONS

An integer array of one or more polygon descriptions. IDL converts and stores this array as 32-bit signed integers. Set this property to a scalar to remove a polygon description array from the object, returning it to its initial empty state. When this property does not contain an array of polygon descriptions, IDL draws a single polygon using the vertices in the order they appear in the vertex list (see the [DATA](#) property).

For details on using this property, see “[Creating Polygon and Polyline Objects](#)” (Chapter 8, *Object Programming*).

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

REJECT

An integer value or an enumerated list item that rejects polygons as being hidden depending on the orientation of their normals. Select from one of the following values:

Value	Property Sheet Value	Description
0	None	No polygons are hidden
1	Normals point away	Polygons whose normals point away from the viewer are hidden
2	Normals point toward	Polygons whose normals point toward the viewer are hidden

Set this property to zero to draw all polygons regardless of the direction of their normals.

Note

The REJECT property has no effect on non-filled polygons (where [STYLE](#) is 0 or 1).

Property Type	ENUMLIST		
Name String	Polygon rejection		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which

the property is being set does not currently share data with another object (that is, if the `SHARE_DATA` property is not in use). This property has no effect if no new data is provided via the `DATA` property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. The default is [0, 255]. This property is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing `IDLgrShader` as a superclass). When there is suitable graphics card hardware support, the polygon is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single `IDLgrShader` object may be associated with additional polygon objects or other graphic objects that have the `SHADER` property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer value or an enumerated list item that represents the type of shading to use:

Value	Property Sheet Value	Description
0	Flat	The color of the first vertex in each polygon is used to define the color for the entire polygon. The color has a constant intensity based upon the normal vector (the default).
1	Gouraud	The colors along each line are interpolated between vertex colors, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object with which data is to be shared by this polygon(s). Polygons may only share data with another polygons object or a polyline. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPolygon object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

Property Type	FLOAT		
Name String	<i>Shininess</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SPECULAR

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Specular highlight color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

STYLE

An integer value or an enumerated list item that specifies how the polygon should be drawn:

Value	Property Sheet Value	Description
0	Points	Only vertices are drawn, using either COLOR or VERT_COLORS
1	Lines	Each polygon is outlined by connecting vertices
2	Filled	The polygon faces are shaded (the default)

Property Type	ENUMLIST		
Name String	Style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_COORD

A 2 by n array containing the texture map coordinates, where n is the number of polygon vertices. Each two-element entry in this array specifies the texture coordinates for the corresponding vertex in the vertex list. One texture coordinate pair should exist for each vertex. Use this property in conjunction with the TEXTURE_MAP property to wrap images over 2-D and 3-D polygons. Default coordinates are not provided.

Texture coordinates are normalized. This means that the $m \times n$ image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTURE_INTERP

A Boolean value or an enumerated list item that indicates whether bilinear sampling is to be used for texture mapping an image onto the polygon(s).

Value	Property Sheet Value	Description
0	Nearest neighbor	Surveys the value of the nearest pixel (the default)
1	Bilinear	Surveys the 4 closest pixels

Note

See “[Interpolation Methods](#)” (Chapter 5, *Using IDL*) for details.

Property Type	ENUMLIST		
Name String	Texture interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_MAP

An object reference to an IDLgrImage object to be texture mapped onto the polygons. The tiling or mapping of the texture is defined expressly by TEXTURE_COORD. If this property is omitted, polygons are filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) To remove a texture map, set TEXTURE_MAP equal to a null object reference.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrPolygon object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend

function `src=alpha` and `dst=1 - alpha`, which corresponds to a `BLEND_FUNCTION` of (3,4) as described for the `IDLgrImage` object.

If the width and/or height of the provided image is not an exact power of two, then the texture map will consist of the given image pixel values resampled to the nearest larger dimensions that are exact powers of two.

Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note

Texture mapping is applied to all styles that are set by the `STYLE` property.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrPolygon` object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Texture map		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points or the thickness of the lines to be drawn when `STYLE` is set to either 0 (Points) or 1 (Lines), in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Note

The value of this property is ignored if `STYLE` is set to 2 (Filled).

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERT_COLORS

A vector of colors used to specify the color of a polygon vertex. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set `VERT_COLORS` to a scalar.

If `VERT_COLORS` is not specified, the entire polygon is drawn in the single color provided by the `COLOR` property, which is the default action.

If `SHADING` is set to 0 (Flat, the default) the color of a polygon is the color of the first vertex of that polygon. Color is interpolated between vertices if `SHADING` is set to 1 (Gouraud).

If there are more vertices than elements in `VERT_COLORS`, the elements of `VERT_COLORS` are cyclically repeated.

Note

If the polygon object is being rendered on a destination device that uses the Indexed color model, and the view that contains the polygon also contains one or more light objects, the `VERT_COLORS` property is ignored and the `SHADE_RANGE` property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[xmin, xmax]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating point vector, [*s*₀, *s*₁], of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that makes it possible to gain finer control over the rendering of textured polygon pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity.

- 1 = Any texels are “skipped” and not rendered at all (the default).
- 0 = The Z-buffer is updated for these pixels and the display image is not affected as noted above.

By updating the Z-buffer without updating the display image, the polygon can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

Note

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Property Type	Boolean		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrPolygon::Cleanup

The IDLgrPolygon::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPolygon::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPolygon::GetCTM

The IDLgrPolygon::GetCTM The IDLgrPolygon::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrPolygon::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polygon object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolygon::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

IDLgrPolygon::GetMultiTextureCoord

The `IDLgrPolygon::GetMultiTextureCoord` returns the texture coordinates associated with a given *Unit*. This method is useful when a shader program defined by an `IDLgrShader` object applies more than a single texture to an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

Obj->[`IDLgrPolygon::`]GetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the `MAX_VERTEX_TEXTURE_IMAGE_UNITS` (for vertex shaders) or `MAX_TEXTURE_IMAGE_UNITS` (for fragment shaders). These values can be returned by `IDLgrWindow::GetDeviceInfo`.

Note

If the specified *Unit* value was never defined and stored in the polygon object using `IDLgrPolygon::SetMultiTextureCoord`, then the variable specified in the *TexCoord* parameter will be set to an undefined variable.

TexCoord

Specifies a variable that contains the current texture coordinates associated with the specified *Unit*. Texture coordinates are stored in this parameter as single precision floating point numbers.

Keywords

None

Examples

See “[Multi-texture Shaders](#)” (Chapter 14, *Object Programming*)

Version History

6.4	Introduced

[IDLgrPolygon::SetMultiTextureCoord](#)

IDLgrPolygon::GetProperty

The IDLgrPolygon::GetProperty procedure method retrieves the value of the property or group of properties for the polygons.

Syntax

Obj->[IDLgrPolygon::]GetProperty[, *PROPERTY=variable*]

Arguments

There are no arguments for this methods.

Keywords

Any property listed under “IDLgrPolygon Properties” on page 4178 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrPolygon::GetVertexAttributeData

The `IDLgrPolygon::GetVertexAttributeData` procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*) for general attribute variable information. This method is useful when a shader program defined by an `IDLgrShader` object modifies the vertices of an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

```
Obj->[IDLgrPolygon:]GetVertexAttributeData, Name, Value
```

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the polygon object using `SetVertexAttributeData`, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using `IDLgrPolygon::SetVertexAttributeData`.

Keywords

None

Examples

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*).

Version History

6.4	Introduced

[IDLgrPolygon::SetVertexAttributeData](#)

IDLgrPolygon::Init

The IDLgrPolygon::Init function method initializes the polygons object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPolygon' [, X [, Y[, Z]]] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPolygon::]Init([X, [Y, [Z]]] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the X, Y, and Z arguments are used to initialize the value of the **DATA** property of the IDLgrPolygon object.

X

A vector argument providing the X coordinates of the vertices. The vector must contain at least three elements. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values.

This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is converted to single precision floating point.

Y

A vector argument providing the Y coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is converted to single precision floating point.

Z

A vector argument providing the Z coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is converted to single precision floating point.

Keywords

Any property listed under [“IDLgrPolygon Properties”](#) on page 4178 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Examples

See [“Mapping an Image onto a Sphere”](#) (Chapter 3, *Image Processing in IDL*) and [Chapter 8, “Polygon and Polyline Objects”](#) (*Object Programming*).

Version History

5.0	Introduced
-----	------------

IDLgrPolygon::SetMultiTextureCoord

The `IDLgrPolygon::SetMultiTextureCoord` procedure method passes texture coordinates to a shader program when the shader program applies more than one texture to an object. The shader program accesses these texture coordinates by using the GLSL predefined uniform variable `gl_MultiTexCoordn`, where *n* corresponds to the *Unit* parameter in this method. This method is useful when a shader program defined by an `IDLgrShader` object applies more than a single texture to an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

Obj->[`IDLgrPolygon::`]SetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the `MAX_VERTEX_TEXTURE_IMAGE_UNITS` (for vertex shaders) or `MAX_TEXTURE_IMAGE_UNITS` (for fragment shaders). These values can be returned by `IDLgrWindow::GetDeviceInfo`. The behavior is undefined for any other setting.

Unit 0 is used by the `TEXTURE_COORD` property on `IDLgrPolygon`. Using unit 0 in this method overrides any texture coordinates specified with the `TEXTURE_COORD` property. Therefore, the `TEXTURE_COORD` property can be used instead of this method if *Unit* is 0.

TexCoord

This data has exactly the same form as the `TEXTURE_COORD` property. IDL converts and maintains this data as single precision floating point. IDL displays an error message and does not draw the object if the number of texture coordinates provided in this parameter is not the same as the number of vertices in the polygon.

IDL stores the texture coordinates in the instance of the graphic object when the application calls this method for the first time with a given *Unit* parameter. If the application calls this method again with a *Unit* number used in a previous call to this

method, IDL replaces the corresponding stored texture coordinates with the contents of the *TexCoord* parameter.

There is no way to remove texture coordinates from an instance of a graphics object. If texture coordinates are associated with a particular texture unit, and the shader program does not reference that unit, the texture coordinates are effectively ignored by the shader program.

Keywords

None

Examples

See “[Multi-texture Shaders](#)” (Chapter 14, *Object Programming*)

IDLgrPolygon:: SetProperty

The IDLgrPolygon::SetProperty procedure method sets the value of the property or group of properties for the polygons.

Syntax

Obj->[IDLgrPolygon::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrPolygon Properties” on page 4178 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrPolygon::SetVertexAttributeData

The `IDLgrPolygon::SetVertexAttributeData` procedure method passes a set of per-vertex attribute data to a vertex shader program. When an `IDLgrShader` object is associated with the polygon via the `SHADER` property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the polygon. If there are more vertices in the polygon than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, “[Advanced Rendering Using Shader Objects](#)” (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this polygon object the first time this method is called. When `SetVertexAttributeData` is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type `float`, `vec2`, `vec3`, `vec4`, `mat2`, `mat3`, or `mat4`. Internally, the `mat2` type is treated as two `vec2` attribute variables, `mat3` as three `vec3` attribute variables, and `mat4` as four `vec4` attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an x-offset and a y-offset for each vertex. The vertex program defines an attribute variable using a `vec4` type so that it can be used in 4x4 general transformations. The IDL program stores the x- and y-offset information in a `[2, n]` array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the `vec4` attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use `IDLgrWindow::GetDeviceInfo` to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrPolygon::]SetVertexAttributeData, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form $[n]$, $[a,n]$, or $[a,a,n]$ where a is 1,2,3, or 4 and n is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (`STYLE=0`) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.  
oPolygon->SetProperty, DATA=vertices
```

```

; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN ;; time samples
    oShader->SetUniformVariable, 'time', t
    oWindow->Draw
ENDFOR

```

And the interesting parts of the vertex shader program are:

```

attribute vec3 velocity;
uniform float time;
void main () {
    vec4 vert;
    vert = gl_Vertex + vec4(velocity * time, 0.0);
    gl_Position = gl_ModelViewProjectMatrix * vert;
}

```

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*) for more information and examples.

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the polyline. The default value of 1.0 causes IDL to draw the line completely opaque. If the value of this property is less than 1.0, then the pixels of the polyline are blended with the pixels already on the screen, where the color of the polyline is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. Note that since a single polyline object may contain many polylines, or because a line may draw in back or in front of itself, the ordering of the polylines within the object (POLYLINES property) must be considered as well.

This property has no effect on devices using indexed color mode.

If 3-channel (RGB) VERT_COLORS are supplied, then the value of this property is used for the alpha at each vertex to draw the line. If 4-channel (RGBA) VERT_COLORS are supplied, then the alpha from each vertex color is used for the alpha at each vertex to draw the line.

When a polyline is drawn with symbols, the symbol's color and alpha values are always used to draw the symbols unless VERT_COLORS are supplied. If the VERT_COLORS are RGB, then the alpha value of the symbol is used to draw the

symbol. If the VERT_COLORS are RGBA, then the alpha from the vertex color is used to draw the symbol.

When used with labels, the value of this property is used as the alpha channel value for a label if its corresponding value in the USE_LABEL_COLOR property is zero and the value of LABEL_USE_VERTEX_COLOR is zero.

If a label's corresponding value in the USE_LABEL_COLOR property is zero and the LABEL_USE_VERTEX_COLOR property is non-zero, then the label is drawn with the alpha value from its corresponding vertex color, if the alpha values are included in the vertex colors. If the vertex colors do not include alpha values, the value of this property is used as the alpha value for the label.

If a label's corresponding value in the USE_LABEL_COLOR property is non-zero, then the value of the label object's ALPHA_CHANNEL property is used to draw the label. In other words, USE_LABEL_COLOR also implies using the label object's alpha as well as its color.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String			
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw polylines. The default color is [0, 0, 0] (black). This property is ignored if the `VERT_COLORS` property is provided.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

A 2-by- n or a 3-by- n floating-point array which defines, respectively, the 2-D or 3-D vertex data. This property is converted to double-precision floating-point values if the `DOUBLE` property is set. Otherwise, it is converted to single-precision floating-point.

Specifying this property is the same as specifying the optional *X*, *Y*, and *Z* arguments to the [IDLgrPolyline::Init](#) method.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object’s depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test

passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LABEL_NOGAPS

An integer vector of values indicating whether gaps should be computed for the corresponding label. A zero value indicates that a gap will be computed for the labels; a non-zero value indicates that no gap will be computed for the label. If the number of labels exceeds the number of elements in this vector, the LABEL_NOGAPS values will be repeated cyclically. By default, gaps are computed for all labels (so that the polyline does not pass through the label).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_OBJECTS

An object reference (or vector of object references) to specify the labels to be drawn along the polyline path(s). The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a label. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a label.

If one or more IDLgrText objects are provided, the LOCATION property of the provided text object(s) may be overwritten; position is determined according to the values provided via the LABEL_OFFSETS property. The labels will have the same color as the corresponding polyline (see the COLOR property) unless the USE_LABEL_COLOR property is specified. The orientation of the label objects USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment for any text labels will each default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

Note

The objects provided via this property will not be destroyed automatically when this IDLgrPolyline is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_OFFSETS

A scalar or vector of floating-point offsets, [t0, t1, ...], that indicate the parametric offsets along the length of each polyline (specified via the LABEL_POLYLINES property) at which each label (as specified via the LABEL_OBJECTS property) would be positioned. If LABEL_OFFSETS is set to a scalar less than zero, then the offsets will be automatically computed to be evenly distributed along the length of the polyline. If a scalar value greater than or equal to zero is provided, it is used for all labels. If a vector is provided, the number of offsets must match the number of labels provided via LABEL_OBJECTS. By default, this property is set to the scalar, -1, indicating that the label offsets will be automatically computed.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_POLYLINES

An integer or integer vector of polyline indices, [P0, P1, ...], that indicate which polylines are to be labeled. Pi corresponds to the ith polyline specified via the POLYLINES property. This property is intended to be used in conjunction with the

LABEL_OBJECTS property. If a scalar is provided, all labels will be drawn along the single indicated polyline. If a vector is provided, the number of polyline indices must match the number of labels provided via LABEL_OBJECTS.

By default, this property is set to the scalar, 0, indicating that only the first polyline will be labeled.

Note

If a given polyline has more than one label, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

Property Type	Integer or integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LABEL_USE_VERTEX_COLOR

An integer value that indicates whether labels should be colored according to the vertex coloring (if the VERT_COLORS property is set).

- A non-zero value = labels should be colored according to the vertex coloring
- Zero (the default) = the label will be drawn using the color specified via the COLOR property of the polyline object (unless the USE_LABEL_COLOR property is set).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LINestyle

An integer or array value that indicates the line style to be used to draw the polyline. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the `IDLgrPalette` object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the

object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPolyline object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

POLYLINES

An integer array of one or more polyline descriptions. IDL converts and stores this array as 32-bit signed integers. Set this property to a scalar to remove a polyline description array from the object, returning it to its initial empty state. When this property does not contain an array of polyline descriptions, IDL draws a single polyline using the vertices in the order they appear in the vertex list (see the [DATA](#) property).

For details on using this property, see [“Creating Polygon and Polyline Objects”](#) (Chapter 8, *Object Programming*).

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the polyline is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional polyline objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer value or enumerated list item representing the type of shading to use:

Value	Property Sheet Value	Description
0	Flat	The color of the second vertex in a line segment is used to define the color for the entire line segment. The color has a constant intensity based upon the normal vector (the default).
1	Gouraud	The colors along each line are interpolated between vertex colors

Property Type	ENUMLIST		
Name String	Shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object whose data is to be shared by this polyline. A polyline may only share data with a polygon object or another polyline. The `SHARE_DATA` property is intended for use when data values are not set via an argument to the object's `Init` method or by setting the object's `DATA` property.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrPolyline` object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference vector containing one or more instances of the `IDLgrSymbol` object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in `SYMBOL`, the elements of the `SYMBOL`

vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set `SYMBOL` to a scalar.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrPolyline` object is destroyed.

Property Type	Object reference vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_LABEL_COLOR

An integer vector of values to indicate whether the `COLOR` property value for the corresponding label object is to be used to draw that label. If the number of labels exceeds the number of elements in this vector, the `USE_LABEL_COLOR` values will be repeated cyclically. By default, this value is zero, indicating that the `COLOR`

property of each label object will be ignored, and the COLOR property for the polyline object will be used instead.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USE_LABEL_ORIENTATION

An integer vector of values to indicate whether the orientation of the corresponding label object is to be used to draw that label. For IDLgrText objects, this refers to the BASELINE and UPDIR property values. For IDLgrSymbol objects, this refers to the default (un-rotated) orientation of the symbol. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_ORIENTATION values will be repeated cyclically. By default, USE_LABEL_ORIENTATION is zero, indicating that the orientation will be automatically computed so that the baseline is parallel to the polyline, and the updir is perpendicular to the polyline.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw those labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the IDLgrText object(s) will be overwritten with default values (0.5 for each, indicating centered labels).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERT_COLORS

A vector of colors to be used to specify the color of the line segment between each vertex. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire polyline is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a line segment is the color of the second vertex of that line segment. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

When VERT_COLORS is used with symbols, the vertex colors and vertex alpha override any colors and alpha specified by the symbol object or any colors and alpha specified by graphic atoms contained in a user-defined symbol.

When VERT_COLORS is used with labels, the application of the color and alpha of the labels is controlled by the USE_LABEL_COLOR and LABEL_USE_VERTEX_COLOR properties.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form [x_{min} , x_{max}] that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [s_0 , s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrPolyline::Cleanup

The IDLgrPolyline::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPolyline::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPolyline::GetCTM

The IDLgrPolyline::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrPolyline::]GetCTM( [, DESTINATION=objref]  
[, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polyline object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolyline::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrPolyline::GetProperty

The IDLgrPolyline::GetProperty procedure method retrieves the value of a property or group of properties for the polylines.

Syntax

Obj->[IDLgrPolyline::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPolyline Properties](#)” on page 4220 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrPolyline::GetVertexAttributeData

The `IDLgrPolyline::GetVertexAttributeData` procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*). This method is useful when a shader program defined by an `IDLgrShader` object modifies the vertices of an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

```
Obj->[IDLgrPolyline::]GetVertexAttributeData, Name, Value
```

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the polyline object using `SetVertexAttributeData`, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using `IDLgrPolyline::SetVertexAttributeData`.

Keywords

None

Examples

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*).

Version History

6.4	Introduced
-----	------------

See Also

[IDLgrPolyline::SetVertexAttributeData](#)

IDLgrPolyline::Init

The IDLgrPolyline::Init function method initializes the polylines object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPolyline' [, X [, Y[, Z]]] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPolyline::]Init([X, [Y, [Z]]] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the X, Y, and Z arguments are used to initialize the value of the **DATA** property of the IDLgrPolyline object.

X

A vector providing the X components of the points to be connected. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Y

A vector providing the Y coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Z

A vector providing the Z coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Keywords

Any property listed under [“IDLgrPolyline Properties”](#) on page 4220 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrPolyline:: SetProperty

The IDLgrPolyline::SetProperty procedure method sets the value of a property or group of properties for the polylines.

Syntax

Obj->[IDLgrPolyline::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrPolyline Properties” on page 4220 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrPolyline::SetVertexAttributeData

The `IDLgrPolyline::SetVertexAttributeData` procedure method passes a set of per-vertex attribute data to a vertex shader program. When an `IDLgrShader` object is associated with the polyline via the `SHADER` property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the polyline. If there are more vertices in the polyline than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, “[Advanced Rendering Using Shader Objects](#)” (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this polyline object the first time this method is called. When `SetVertexAttributeData` is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type `float`, `vec2`, `vec3`, `vec4`, `mat2`, `mat3`, or `mat4`. Internally, the `mat2` type is treated as two `vec2` attribute variables, `mat3` as three `vec3` attribute variables, and `mat4` as four `vec4` attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an *x*-offset and a *y*-offset for each vertex. The vertex program defines an attribute variable using a `vec4` type so that it can be used in 4x4 general transformations. The IDL program stores the *x*- and *y*-offset information in a `[2, n]` array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the `vec4` attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use `IDLgrWindow::GetDeviceInfo` to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrPolyline::](#)SetVertexAttributeData, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form $[n]$, $[a,n]$, or $[a,a,n]$ where a is 1,2,3, or 4 and n is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (`STYLE=0`) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.  
oPolygon-> SetProperty, DATA=vertices
```

```

; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN ;; time samples
    oShader->SetUniformVariable, 'time', t
    oWindow->Draw
ENDFOR

```

And the interesting parts of the vertex shader program are:

```

attribute vec3 velocity;
uniform float time;
void main () {
    vec4 vert;
    vert = gl_Vertex + vec4(velocity * time, 0.0);
    gl_Position = gl_ModelViewProjectMatrix * vert;
}

```

See “[Vertex Shaders](#)” (*Object Programming*) for more information and examples.

IDLgrPrinter

A printer object represents a hardcopy graphics destination. When a printer object is created, the printer device to which it refers is the default system printer. To change the printer, utilize the printer dialogs (see [“DIALOG_PRINTJOB”](#) on page 654 and [“DIALOG_PRINTERSETUP”](#) on page 652.)

Note

Objects or subclasses of this type can not be saved or restored.

Superclasses

None

Creation

See [“IDLgrPrinter::Init”](#) on page 4273.

Properties

Objects of this class have the following properties. See [“IDLgrPrinter Properties”](#) on page 4255 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GAMMA](#)
- [GRAPHICS_TREE](#)
- [LANDSCAPE](#)
- [N_COLORS](#)
- [N_COPIES](#)
- [NAME](#)
- [PALETTE](#)
- [PRINT_QUALITY](#)
- [PRINTER_NAME](#)

- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [UNITS](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrPrinter::Cleanup](#)
- [IDLgrPrinter::Draw](#)
- [IDLgrPrinter::GetContiguousPixels](#)
- [IDLgrPrinter::GetFontnames](#)
- [IDLgrPrinter::GetProperty](#)
- [IDLgrPrinter::GetTextDimensions](#)
- [IDLgrPrinter::Init](#)
- [IDLgrPrinter::NewDocument](#)
- [IDLgrPrinter::NewPage](#)
- [IDLgrPrinter::QueryRequiredTiles](#)
- [IDLgrPrinter::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

See [Chapter 12, “Displaying, Copying and Printing Objects”](#) (*Object Programming*) for information on the `IDLgrPrinter` object. See [“Positioning Objects Within a Page”](#) (Chapter 12, *Object Programming*) for additional examples that define the locations of objects within the hardcopy page.

The following example demonstrates the process of printing the contents of an IDL graphics display object (a buffer or a window) to an `IDLgrPrinter` object. The resolution of the printed page is based on the resolution of the screen. The model object in the printer object must be scaled to maintain the same size as displayed on

the screen. The location of the view must also be changed to center the display on the page.

```

PRO PrintingAnImage

; Determine the path to the "convec.dat" file.
convecFile = FILEPATH('convec.dat', $
    SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the image with the file.

IDLgrPrinter Properties

IDLgrPrinter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrPrinter::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrPrinter::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrPrinter::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GAMMA](#)
- [GRAPHICS_TREE](#)
- [LANDSCAPE](#)
- [N_COLORS](#)
- [N_COPIES](#)
- [NAME](#)
- [PALETTE](#)
- [PRINT_QUALITY](#)
- [PRINTER_NAME](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [UNITS](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value or an enumerated list item that determines the color model to be used for the printer buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color Index

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the overall drawable area that may be printed on a page. By default, the dimensions are measured in device units (refer to the [UNITS](#) property).

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

GAMMA

An object reference to an IDLgrPalette object whose entries will be used as the gamma correction table for color printing. Gamma correction only applies if COLOR_MODEL=1 (Indexed).

When the color palette (specified via the PALETTE property) is loaded for the printer, if a gamma correction table is provided, then each of the [R,G,B] entries in the color palette will be translated through the gamma correction table. For example, at color index *i*:

```
correctedRed[i] = gammaRed[paletteRed[i]]
correctedGreen[i] = gammaGreen[paletteGreen[i]]
correctedBlue[i] = gammaBlue[paletteBlue[i]]
```

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPrinter object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LANDSCAPE

A Boolean value that indicates whether to produce hardcopy output in landscape mode. The default value of zero indicates Portrait mode.

Note

The printer driver may not support the LANDSCAPE option; in general, it is best to use the printer dialogs to set orientation.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that indicates the number of colors (between 2 and 256) to be used if the COLOR_MODEL is set to Indexed (1). This property is ignored if the COLOR_MODEL is set to RGB (0).

Property Type	Integer		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

N_COPIES

An integer that determines the number of copies of print data to be generated. The default is 1 copy.

Note

Your specific printer driver may not support the N_COPIES option. You can also use the printer dialogs to set the number of copies.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string giving the human-readable name of this object. This property is initialized to the network name of the printer unless another value is set during initialization.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table if the Indexed color model is used.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrPrinter object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PRINT_QUALITY

An integer value indicating the print quality at which graphics are to be drawn to the printer. Note that the print quality is independent of the rendering quality (as set by the QUALITY property). Valid values are:

- 0 = Low
- 1 = Normal (this is the default)
- 2 = High

Generally, setting the print quality to a lower value will increase the speed of the printing job, but decrease the resolution; setting it to a higher value will cause the printing job to take more time, but will increase the resolution.

Note

Some printer drivers may not be able to support different printing qualities. In these cases, the setting of the PRINT_QUALITY property will be quietly ignored.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PRINTER_NAME

A string containing the network name of the printer, (e.g., '\\BORG\HpJet').

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

QUALITY

An integer value or enumerated list item that indicates the rendering quality at which graphics are to be drawn to this destination. Note that the rendering quality is independent of the print quality (as set by the PRINT_QUALITY property). Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A floating-point vector of the form [*xres*, *yres*] defining the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Property Type	FLOAT		
Name String	Resolution		
Get: Yes	Set: No	Init: No	Registered: Yes

UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the drawable area on a page.

Note

If you change the value of the UNITS property (using the SetProperty method), IDL will convert the current value of the DIMENSIONS property to the new units.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrPrinter::Cleanup

The IDLgrPrinter::Cleanup procedure method performs all cleanup on the object. If a document is open (that is, if graphics have been draw to the printer), the document is closed and the pending graphics are sent to the current printer.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrPrinter:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::Draw

The IDLgrPrinter::Draw procedure method draws the given picture to this graphics destination.

Printing in Bitmap or Vector Graphic Mode

The IDLgrPrinter::Draw method VECTOR keyword generates output in bitmap or vector format. The following table shows the keyword options and results for each platform.

Keyword Settings	Windows Printer Output	UNIX File Type
VECTOR = 0	Bitmap (BMP)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)
VECTOR = 1	Enhanced MetaFile (EMF)	Encapsulated PostScript (EPS) file (e.g. xprinter.eps)

Table 31-14: File Types Produced by IDLgrPrinter Draw Method

Because Windows printer output is usually sent directly to the printer, EMF and BMP files are not viewable. On UNIX, the printer output is usually directed to a file named xprinter.eps by default.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them when VECT_SORTING=0. Otherwise, objects are drawn to the destination device based on their average depth value. See “[Bitmap and Vector Graphic Output](#)” (Chapter 12, *Object Programming*) for more information on bitmap and vector output.

Syntax

```
Obj->[IDLgrPrinter::]Draw [, Picture] [, VECT_SORTING={ 0 | 1 } ]
    [, VECT_TEXT_RENDER_METHOD={ 0 | 1 } ] [, VECTOR={ 0 | 1 } ]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an [IDLgrViewgroup](#) object), or scene (an instance of an [IDLgrScene](#) object) to be drawn.

Keywords

VECT_SORTING

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way object primitives in a picture appear in the destination. Valid values are:

- 0 = disable sorting. This causes the object primitives to appear in the vector output file in the same order they are drawn on the display device. This is the order in which they appear in the graphics tree.
- 1 = enable sorting (default). Objects are ordered from back to front based on each primitive object's average depth value.

Note

Objects that intersect each other, [IDLgrImage](#) objects (which do not update the depth buffer), and objects contained within transparent views may not sort correctly. See “[Controlling What is Displayed in Vector Graphics](#)” (Chapter 12, *Object Programming*) for details.

VECT_TEXT_RENDER_METHOD

This keyword has an effect only when generating vector output (VECTOR=1).

This keyword controls the way text is rendered in a vector graphic file. Valid values are:

- 0 = render text as text primitives (default). Use the output device's text primitives when rendering text.
- 1 = render text as primitives composed of triangles. Render text in the vector file as a series of filled triangles. This produces text that closely matches the text on the display device, but the output file size is larger.

Note

When using the IDLgrPrinter object under UNIX, the Xprinter output is regarded as write-only. As there is no support for 3-D text, IDL always generates filled triangles when rendering text in the Xprinter output. On Windows, the vector output is always Enhanced MetaFile (EMF) file format. Because printer output is usually sent directly to the printer the EMF file cannot be seen by the user.

Note

See [“Text Rendering in Vector Graphics”](#) (Chapter 12, *Object Programming*) for more information.

VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values are:

- 0 = generate bitmap graphics (default). Render the scene to a buffer and then copy the buffer to the printer in bitmap format. The bitmap retains the quality of the original image.
- 1 = generate vector graphics. Render the scene using simple vector operations that result in a representation of the scene that is scalable to the printer. The vector representation, which is sent to the printer, does not retain all the attributes of the original image.

Note

Transparent objects in a view are not rendered in vector graphic files. Semi-transparent objects are rendered fully opaque. See [“Bitmap and Vector Graphic Output”](#) (Chapter 12, *Object Programming*) for a complete discussion of when to output to bitmap or vector graphics based on picture content.

Version History

5.0	Introduced
6.1	Added VECT_SORTING, VECT_TEXT_RENDER_METHOD keywords

IDLgrPrinter::GetContiguousPixels

The IDLgrPrinter::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

Syntax

```
Result = Obj->[IDLgrPrinter::]GetContiguousPixels()
```

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::GetFontnames

The IDLgrPrinter::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrPrinter::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string ] )
```

Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, '', only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::GetProperty

The IDLgrPrinter::GetProperty procedure method retrieves the value of a property or group of properties for the printer.

Syntax

Obj->[IDLgrPrinter:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrPrinter Properties](#)” on page 4255 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::GetTextDimensions

The `IDLgrPrinter::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the `IDLgrText RECOMPUTE_DIMENSIONS` property.

Syntax

Result = *Obj*->[IDLgrPrinter::]GetTextDimensions(*TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*])

Return Value

Returns a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values represent the distance to travel (parallel to the `UPDIR` vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an `IDLgrText` object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrPrinter::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::Init

The IDLgrPrinter::Init function method initializes the printer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrPrinter' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrPrinter::]Init( [, PROPERTY=value)  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrPrinter Properties” on page 4255 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::NewDocument

The IDLgrPrinter::NewDocument procedure method closes the current document (a page or group of pages), which causes any pending output to be sent to the printer, finishing the printer job.

Syntax

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrPrinter::QueryRequiredTiles

The `IDLgrPrinter::QueryRequiredTiles` function method is used in conjunction with an `IDLgrImage` object that supports tiling. Initially, this type of `IDLgrImage` object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the `Draw` method is called, the destination object contains the image tiles that are the results of this method's query.

Note

Printer support of tiled images is not available in vector mode (when the `IDLgrPrinter::Draw` method `VECTOR` keyword is set to 1). The bitmap mode (`VECTOR=0`) must be used.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that `COUNT` is greater than 0 before accessing the returned array.

Note

Printers are normally a higher resolution than a monitor; therefore higher resolution levels will be requested when calling `QueryRequiredTiles` on an `IDLgrPrinter`. `QueryRequiredTiles` on `IDLgrPrinter` also considers the value in the `IDL_GR_TILECACHESIZE` preference when calculating the required level. If the data for the required tiles at the required level will not fit in `IDL_GR_TILECACHESIZE`, the next-lower resolution level will be tried. This is repeated until a level that fits is found and this is returned by `QueryRequiredTiles`. This can be overridden by setting `TILE_LEVEL_MODE` to 0 (manual) and setting the required level in `TILE_CURRENT_LEVEL` on the tiled `IDLgrImage` before calling `QueryRequiredTiles`. However, if the total data exceeds `IDL_GR_TILECACHESIZE`, then some tiles will print blank. If there is sufficient RAM in the system, `IDL_GR_TILECACHESIZE` can be increased to enable higher-resolution printing. Setting 0 will allow an unlimited amount of tile data to be set, but note that printing may fail if all physical RAM is used.

Note

If the device is in Color Index mode (`COLOR_MODEL=1`) or the image has [RENDER_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

Syntax

```
Result = Obj->[IDLgrPrinter::]QueryRequiredTiles( View, Image
  [, ALL_VISIBLE=value] [, COUNT=variable] [, PATH=objref(s)] )
```

Return Value

Returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 31-15: IDLIMAGETILE Structure

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these

tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 31-9: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note

See “[Image Tiling](#)” (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.

Arguments

View

An object reference to the `IDLgrView` object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled `IDLgrImage` object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if `QueryRequiredTiles` should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of `PATH`, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the `PARENT` properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

6.2	Introduced
7.0	Added <code>PATH</code> keyword to <code>QueryRequiredTiles</code> to handle aliases.

IDLgrPrinter:: SetProperty

The IDLgrPrinter::SetProperty procedure method sets the value of a property or group of properties for the printer.

Syntax

Obj->[IDLgrPrinter::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “IDLgrPrinter Properties” on page 4255 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrROI

The IDLgrROI object class is an object graphics representation of a region of interest.

Superclasses

[IDLanROI](#)

[IDLitComponent](#)

Creation

See “[IDLgrROI::Init](#)” on page 4298.

Properties

Objects of this class have the following properties. See “[IDLgrROI Properties](#)” on page 4284 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SHADER](#)
- [STYLE](#)
- [SYMBOL](#)

- [THICK](#)
- [XCOORD_CONV](#)
- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZCOORD_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLgrROI object class has the following methods:

- [IDLgrROI::Cleanup](#)
- [IDLgrROI::GetProperty](#)
- [IDLgrROI::Init](#)
- [IDLgrROI::PickVertex](#)
- [IDLgrROI::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.3	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL property
6.4	Added SHADER property

IDLgrROI Properties

IDLgrROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrROI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrROI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrROI::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [DOUBLE](#)
- [HIDE](#)
- [LINESTYLE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SHADER](#)
- [STYLE](#)
- [SYMBOL](#)
- [THICK](#)
- [XCOORD_CONV](#)

- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZCOORD_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLanROI](#)
- [IDLitComponent](#)

ALL

An anonymous structure with the values of all of the properties associated with the state of this object. State information about the object may include things like color, line style, etc., but not vertex data or user values.

Note

The fields in this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the ROI. The default value of 1.0 causes IDL to draw the ROI completely opaque. If the value of this property is less than 1.0, then the pixels of the ROI are blended with the pixels already on the screen, where the color of the ROI is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

When the ROI is drawn with symbols, the symbol color and alpha values are always used to draw the symbols.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

A color index or a three-element vector [*red*, *green*, *blue*] specifying the color used to draw the region. The default color is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object’s depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test

passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value or enumerated list item indicating whether this region should be drawn:

Value	Property Sheet Value	Description
0	True	Draw the region (the default)
1	False	Do not draw the region

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer that indicates the line style to be used to draw the region. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern. To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

In a property sheet, this property appears as follows:

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) that defines the color palette of this object. This property is only used for Object Graphics destinations using the RGB color model. In this case, if the color value for the region is specified as a color index value, this palette is used to look up the color for the region. If the PALETTE property is not set, the destination object PALETTE property is used, which defaults to a gray scale ramp.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrROI object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the ROI is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional ROI objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

STYLE

An integer value that indicates the geometrical primitive to use to represent the region when displayed. Valid values include:

- 0 = points
- 1 = open polyline
- 2 = closed polyline (the default)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SYMBOL

An object reference to an [IDLgrSymbol](#) object for the symbol used for display when `STYLE = 0` (points). By default, a dot is used.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrROI` object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points, or the thickness of the lines, measured in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	THICKNESS		
Name String	Thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Double-precision floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[x_{min}, x_{max}]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrROI::Cleanup

The IDLgrROI::Cleanup procedure method performs all cleanup for a region of interest object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrROI::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

5.3	Introduced
-----	------------

IDLgrROI::GetProperty

The IDLgrROI::GetProperty procedure method retrieves the value of a property or group of properties for the Object Graphics region.

Syntax

Obj->[IDLgrROI::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrROI Properties” on page 4284 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.3	Introduced
-----	------------

IDLgrROI::Init

The IDLgrROI::Init function method initializes an Object Graphics region of interest.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLgrROI' [, X[, Y[, Z]]] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrROI::]Init([X[, Y[, Z]]] [, PROPERTY=value])  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

Y

A vector providing the Y components of the vertices. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero. Otherwise it is converted and stored as single precision floating point.

Z

A scalar or vector providing the Z components of the vertices. If not provided, Z values default to 0.0. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero. Otherwise it is converted and stored as single precision floating point.

Keywords

Any property listed under [“IDLgrROI Properties”](#) on page 4284 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.3	Introduced
-----	------------

IDLgrROI::PickVertex

The IDLgrROI::PickVertex function method picks a vertex of the region which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = *Obj*->[IDLgrROI::]PickVertex(*Dest*, *View*, *Point* [, **PATH**=*objref*])

Return Value

Returns the index of the nearest region vertex. If two or more vertices are equally nearest to the point, the smallest index of those vertices is returned.

Arguments

Dest

An object reference to an [IDLgrWindow](#) or [IDLgrBuffer](#) for which the pick is to occur.

View

An object reference to the [IDLgrView](#) containing this region.

Point

A two-element vector, [x, y], representing the device location used for picking a nearest vertex.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected vertex is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

5.3	Introduced
-----	------------

IDLgrROI:: SetProperty

The IDLgrROI::SetProperty procedure method sets the value of a property or group of properties for the Object Graphics region.

Syntax

Obj->[IDLgrROI::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrROI Properties” on page 4284 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced
-----	------------

IDLgrROIGroup

The IDLgrROIGroup object class is an Object Graphics representation of a group of regions of interest.

Superclasses

[IDLanROIGroup](#).

[IDLitComponent](#)

Creation

See “[IDLgrROIGroup::Init](#)” on page 4316.

Properties

Objects of this class have the following properties. See “[IDLgrROIGroup Properties](#)” on page 4305 for details on individual properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [PARENT](#)
- [SHADER](#)
- [XCOORD_CONV](#)
- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZCOORD_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

The IDLgrROIGroup class has the following methods:

- [IDLgrROIGroup::Add](#)
- [IDLgrROIGroup::Cleanup](#)
- [IDLgrROIGroup::GetProperty](#)
- [IDLgrROIGroup::Init](#)
- [IDLgrROIGroup::PickRegion](#)
- [IDLgrROIGroup::Remove](#)
- [IDLgrROIGroup::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.3	Introduced
5.6	Added CLIP_PLANES property
6.4	Added SHADER property Added Remove method

IDLgrROIGroup Properties

IDLgrROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrROIGroup::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrROIGroup::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrROIGroup::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [HIDE](#)
- [PARENT](#)
- [SHADER](#)
- [XCOORD_CONV](#)
- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZCOORD_CONV](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLanROIGroup](#).
- [IDLitComponent](#)

ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

Note

The fields in this structure may change in subsequent releases of IDL.

Note

This structure returns ALPHA_CHANNEL and COLOR properties that are consistent with other graphic objects. However, neither property is used by the IDLgrROIGroup object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of `LESS`. A model may also set a depth test function value. The graphics device compares the object’s depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object’s pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see `DEPTH_TEST_DISABLE` property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value indicating whether this region group should be drawn:

- 0 = draw the region group (the default)
- 1 = do not draw the region group.

Property Type	BOOLEAN		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing `IDLgrShader` as a superclass). When there is suitable graphics card hardware support, the ROI group is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single

IDLgrShader object may be associated with additional ROI group objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}), 1.0/(X_{max} - X_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[x_{min}, x_{max}]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}), 1.0/(Y_{max} - Y_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}), 1.0/(Z_{max} - Z_{min})]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrROIGroup::Add

The IDLgrROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLgrROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

Syntax

Obj->[IDLgrROIGroup::]Add, *ROI*

Arguments

ROI

A reference to an instance of the IDLgrROI object class representing the region of interest to add to the group.

Keywords

Accepts all keywords accepted by the IDLanROIGroup::Add method.

Version History

5.3	Introduced
-----	------------

IDLgrROIGroup::Cleanup

The IDLgrROIGroup::Cleanup procedure method performs all cleanup for an Object Graphics region of interest group object.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrROIGroup:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.3	Introduced
-----	------------

IDLgrROIGroup::GetProperty

The IDLgrROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

Syntax

Obj->[IDLgrROIGroup::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrROIGroup Properties” on page 4305 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.3	Introduced
-----	------------

IDLgrROIGroup::Init

The IDLgrROIGroup::Init function method initializes an Object Graphics region of interest group object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrROIGroup' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrROIGroup::]Init([, *PROPERTY=value*]) *(In a lifecycle method only.)*

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrROIGroup Properties” on page 4305 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.3	Introduced
-----	------------

IDLgrROIGroup::PickRegion

The IDLgrROIGroup::PickRegion function method picks a region within the group which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

Syntax

Result = *Obj*->[IDLgrROIGroup::]PickRegion(*Dest*, *View*, *Point* [, **PATH**=*objref*])

Return Value

Returns the object reference of the nearest region. If two or more regions are equally nearest to the point, the one that was added to the region group first is returned.

Arguments

Dest

An object reference to an [IDLgrWindow](#) or [IDLgrBuffer](#) for which the pick is to occur.

View

An object reference to the [IDLgrView](#) containing this region.

Point

A two-element vector, [x, y], representing the device location to use for picking a nearest region.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected region is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Version History

5.3	Introduced
-----	------------

IDLgrROIGroup::Remove

The IDLgrROIGroup::Remove procedure method removes an object from the ROI group.

Syntax

```
Obj->[IDLgrROIGroup:]Remove [, Child_object] [, POSITION=index] [, /ALL]
```

Arguments

Child_object

An object reference or array of object references for the objects to be removed from the ROI group. If *Child_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the ROI group will be removed.

Keywords

ALL

Set this keyword to remove all objects from the ROI group. If this keyword is set, the *Child_object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child_object* argument is supplied, this keyword is ignored.

Version History

6.4	Introduced
-----	------------

IDLgrROIGroup:: SetProperty

The IDLgrROIGroup::Set Property procedure method sets the value of a property or group of properties for the region group.

Syntax

Obj->[IDLgrROIGroup::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrROIGroup Properties” on page 4305 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.3	Introduced
-----	------------

IDLgrScene

A scene object represents the entire scene to be drawn and serves as a container of [IDLgrView](#) or [IDLgrViewgroup](#) objects.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrScene::Init](#)” on page 4332.

Properties

Objects of this class have the following properties. See “[IDLgrScene Properties](#)” on page 4324 for details on individual properties.

- [ALL](#)
- [COLOR](#)
- [HIDE](#)
- [REGISTER_PROPERTIES](#)
- [TRANSPARENT](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrScene::Add](#)
- [IDLgrScene::Cleanup](#)
- [IDLgrScene::GetByName](#)
- [IDLgrScene::GetProperty](#)
- [IDLgrScene::Init](#)
- [IDLgrScene::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
-----	------------

IDLgrScene Properties

IDLgrScene objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrScene::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrScene::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrScene::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [COLOR](#)
- [HIDE](#)
- [REGISTER_PROPERTIES](#)
- [TRANSPARENT](#)

In addition, objects of this class inherit:

- [IDL_Container](#)
- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR

The color to which the scene should be erased before drawing. The color may be specified as a color lookup table index or a three-element vector [*red*, *green*, *blue*].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Background color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: No	Set: No	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

For IDLgrScene, the available properties (and their iTool data types) are:

- HIDE (Boolean)

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TRANSPARENT

A Boolean value that determines whether to disable window clearing. If this property is not set, the destination object in use by the scene is automatically erased when the scene is initialized.

Property Type	BOOLEAN		
Name String	Transparent		
Get: Yes	Set: Yes	Init: No	Registered: Yes

IDLgrScene::Add

The IDLgrScene::Add function method verifies that the added item is an instance of an [IDLgrView](#) or IDLgrViewgroup object. If it is, IDLgrScene.Add adds the view or viewgroup to the specified scene.

Syntax

Obj->[[IDLgrScene::](#)]Add, *View* [, [POSITION](#)=*index*]

Arguments

View

An instance of the [IDLgrView](#) or [IDLgrViewgroup](#) object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.0	Introduced
-----	------------

IDLgrScene::Cleanup

The IDLgrScene::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrScene::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrScene::GetByName

The `IDLgrScene::GetByName` function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the `GetByName` function returns a null object reference.

Note

The `GetByName` function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrScene:]GetByName(*Name*)

Return Value

Returns the object reference to the named object. If the named object is not found, returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the `GetByName` method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrScene::GetProperty

The IDLgrScene::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

Syntax

Obj->[IDLgrScene::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrScene Properties” on page 4324 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrScene::Init

The IDLgrScene::Init function method initializes the scene object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrScene' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrScene::]Init( [, PROPERTY=value])  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrScene Properties” on page 4324 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrScene:: SetProperty

The IDLgrScene::SetProperty procedure method sets the value of a property or group of properties for the buffer.

Syntax

Obj->[IDLgrScene::]SetProperty[, *PROPERTY=**value*]

Arguments

None

Keywords

Any property listed under “[IDLgrScene Properties](#)” on page 4324 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrShader

A *shader object* provides access to the hardware-based processing power available on some modern graphics cards. This allows computationally intensive image processing operations to be delegated to the Graphics Processing Unit (GPU) of a suitable graphics card, dramatically increasing performance and interactivity. A shader program can perform image filtering operations, complex lighting and shading calculations, interactive blending of multiple textures, animation of object vertices, or any combination of these.

See “[Hardware Requirements for Shaders](#)” (*Object Programming*) for information on graphics cards and how to determine whether the graphics card supports this shader functionality. If there is not sufficient support for the shader program, IDL draws the scene graph as if there was no shader object present.

Note

See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for valuable overview information about using shader programs with IDL and for a wide range of examples.

Warning

Setting IDLgrImage `RENDER_METHOD=1` (do not render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

Superclasses

Objects of this class have no superclass.

Creation

See [IDLgrShader::Init](#).

Properties

Objects of this class have the following properties. See “[IDLgrShader Properties](#)” on page 4337 for details on individual properties.

- [CACHE_RESULT](#)
- [FORCE_FILTER](#)

- [FRAGMENT_PROGRAM_FILENAME](#)
- [FRAGMENT_PROGRAM_STRING](#)
- [OUTPUT_DATA_TYPE](#)
- [VERTEX_PROGRAM_FILENAME](#)
- [VERTEX_PROGRAM_STRING](#)

In addition, objects of this class inherit the properties of all superclasses of this class, if any.

Methods

This class has the following methods:

- [IDLgrShader::Cleanup](#)
- [IDLgrShader::Filter](#)
- [IDLgrShader::GetProperty](#)
- [IDLgrShader::GetUniformVariable](#)
- [IDLgrShader::Init](#)
- [IDLgrShader::SetProperty](#)
- [IDLgrShader::SetUniformVariable](#)

In addition, this class inherits the methods of its superclasses, if any.

Examples

See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*).

Version History

6.4	Introduced
-----	------------

See Also

[IDLgrShaderBytscl](#), [IDLgrShaderConvolve3](#), [IDLgrFilterChain](#), [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*)

IDLgrShader Properties

IDLgrShader objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrShader::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrShader::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrShader::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties:

- [CACHE_RESULT](#)
- [FORCE_FILTER](#)
- [FRAGMENT_PROGRAM_FILENAME](#)
- [FRAGMENT_PROGRAM_STRING](#)
- [OUTPUT_DATA_TYPE](#)
- [VERTEX_PROGRAM_FILENAME](#)
- [VERTEX_PROGRAM_STRING](#)

CACHE_RESULT

If a shader object is associated with an IDLgrImage object, you may set this property to determine whether a shader program is executed every time Draw is called as follows:

Value	Description
0	The default. Apply the shader each time Draw is called. This is suitable for applications with a fast graphics card or one that is interactively updated by uniform variable parameter changes. (Reaching the image each time the shader is changed carries a performance penalty.)
Non-zero	Cache the result of applying the shader and use this cached result in subsequent renderings. This setting is appropriate for slow graphics cards or applications that requires fast redraw capabilities such as when panning or zooming.

If a software fallback is in use or the image is part of an IDLgrFilterChain, the value of this property is ignored and the result of applying the shader is always cached. This property is ignored if the shader object is associated with any object other than IDLgrImage. The default value is 0.

Note

Your graphics card must support [FRAMEBUFFER_OBJECT_EXTENSION](#) when you request caching (CACHE_RESULT=1). You can determine this support using [IDLgrWindow::GetDeviceInfo](#).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FORCE_FILTER

Set this scalar long property to a non-zero value to cause IDL to call the IDLgrShader subclass Filter method, even if the graphics hardware supports shaders. This is useful for developing and testing the software fallback option on devices that have the

hardware support. The default value for this property is zero. This property can only be set at Init time.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

FRAGMENT_PROGRAM_FILENAME

This property is a scalar string containing the complete filepath specifying a text file that contains the fragment program text. If specified, IDL ignores the [FRAGMENT_PROGRAM_STRING](#) property. If the file does not exist when IDL draws the scene using this shader, IDL reports an informational error and continues drawing without the shader program.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FRAGMENT_PROGRAM_STRING

This property is a scalar string that contains the fragment program text. If your application maintains the program as an array of strings, one for each program line, use STRJOIN to create a single string that is suitable for this property. Specify a newline string (10B) as the delimiter in STRJOIN so that the shader program compiler can report a useful line number in any compilation error messages. For example:

```
programString = STRJOIN(pgmStrings, STRING(10B))
```

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUTPUT_DATA_TYPE

This property controls the precision of data storage used for an interim image when the following conditions apply to the shader object:

- It is associated with an `IDLgrImage` object
- It is being executed on the GPU of the graphics card (suitable hardware is available)
- It is either contained in an `IDLgrFilterChain` object or `CACHE_RESULT=1`.

This scalar long property may be set to one of the following values:

Value	Description
1	BYTE
2	FLOAT16
3	FLOAT32 (the default)

When the `IDLgrShader` is in an `IDLgrFilterChain`, `OUTPUT_DATA_TYPE` specifies the precision of the temporary storage used to pass data from one shader to the next in the chain. When `CACHE_RESULT` is set to 1, `OUTPUT_DATA_TYPE` specifies the precision of the cache used to store the result of the shader operation.

Note

If you will be capturing the image data during or after applying the shaders, the `OUTPUT_DATA_TYPE` property and the `DATA_TYPE` keyword of `IDLgrImage::ReadFilteredData` should have consistent values.

Note

For best performance use the lowest precision possible without loss of data.

The default value is 3.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERTEX_PROGRAM_STRING

This property is a scalar string that contains the vertex program text. If your application maintains the program as an array of strings, one for each program line, use STRJOIN to create a single string that is suitable for this property. Specify a newline string (10B) as the delimiter in STRJOIN so that the shader program compiler can report a useful line number in any compilation error messages. For example:

```
programString = STRJOIN(pgmStrings, STRING(10B))
```

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERTEX_PROGRAM_FILENAME

This property is a scalar string containing the complete filepath specifying a text file that contains the vertex program text. If specified, IDL ignores the [VERTEX_PROGRAM_STRING](#) property. If the file does not exist when IDL draws the scene using this shader, IDL reports an informational error and continues drawing without the shader program.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrShader::Cleanup

The IDLgrShader::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrShader::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLgrShader::Filter

The IDLgrShader::Filter function method, implemented only in an IDLgrShader subclass, provides a way to implement a software-based fallback for an image filtering shader program when the graphics card hardware does not support shading language.

This function is only available for shader objects associated with IDLgrImage objects, and is activated only when the required hardware support is not present or when the [FORCE_FILTER](#) property of the shader object or IDLgrFilterChain object is set to a non-zero value.

Note

Never call this method directly. It is called automatically in response to changes requiring a re-draw of the scene, including [IDLgrShader::SetUniformVariable](#) updates.

This method should not be included in a subclassed shader object attached to texture mapped IDLgrSurface or IDLgrPolygon object (where an image is associated via the TEXTURE_MAP property). A software fallback option is not available in such cases.

Syntax

```
Result = Obj->[IDLgrShader subclass::]Filter( Image )
```

Return Value

Returns an IDL array containing the resulting filtered image. The array must have the same dimensions and type as the incoming image. If the returned array does not meet these requirements, IDL ignores the array and draws the image with its original data.

This method should apply the desired operation to the image data and return that data as its function return value. IDL clamps the returned image data to the range [0.0, 1.0] and converts this range into the pixel component range appropriate for the device. In most cases, this is [0, 255].

Arguments

Image

An array containing the image data. This array is always of type FLOAT and contains RGBA components arranged in PIXEL_INTERLEAVE format, [4, cols, rows].

Keywords

None.

Examples

The following code segment shows an implementation of the `Filter` method in an object, `shader_rgb_doc`, that subclasses from `IDLgrShader`. Within the method, access the RGBA floating-point, pixel-interleaved data in `Image`. Alter the intensity of each red, green, and blue channel based on values (`s`) contained in the uniform variable (`scl`). Return the filtered image. See [“Altering RGB Levels Using a Shader”](#) (Chapter 14, *Object Programming*) for expository details.

```
Function shader_rgb_doc::Filter, Image

newImage=Image
self->GetUniformVariable, 'scl', s
newImage[0,*,*] *= s[0]
newImage[1,*,*] *= s[1]
newImage[2,*,*] *= s[2]

RETURN, newImage

END
```

Example Code

See `shader_rgb_doc__define.pro` for the complete, working example, which is located in the `examples/doc/shaders` subdirectory of the IDL distribution. Run the example by creating an instance of the object at the IDL command prompt using `orgbshader=OBJ_NEW("shader_rgb_doc")` or view the file in an IDL Editor window by entering `shader_rgb_doc__define.pro`.

[IDLgrShader::SetUniformVariable](#)

IDLgrShader::GetProperty

The `IDLgrShader::GetProperty` procedure method returns the value of a property or group of properties for the shader.

Syntax

Obj->[`IDLgrShader::`]GetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrShader Properties](#)” on page 4337 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.4	Introduced
-----	------------

IDLgrShader::GetUniformVariable

The `IDLgrShader::GetUniformVariable` procedure method returns the value of a named uniform variable. A uniform variable provides a way to pass small amounts of data to a shader program. It can enable interactivity by linking user interface control changes to program updates.

The `GetUniformVariable` method is typically called inside the `IDLgrShader::Filter` method, which is used to provide a software-based alternative to a hardware-based image processing shader program. See “[Examples](#)” on page 4344 for such a sample program.

Note

For information about uniform variables, see “[Uniform Variables](#)” (Chapter 14, *Object Programming*).

Syntax

Obj->[`IDLgrShader::`]GetUniformVariable, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the uniform variable to retrieve.

Note

If the *Name* argument specifies a uniform variable that was never defined and stored in the shader object using `SetUniformVariable`, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the uniform variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using `IDLgrShader::SetUniformVariable`.

Keywords

None.

[IDLgrShader::SetUniformVariable](#)

IDLgrShader::Init

The IDLgrShader::Init function method initializes the shader object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrShader' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrShader::]Init([, PROPERTY=value]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None.

Keywords

Any property listed under “IDLgrShader Properties” on page 4337 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced
-----	------------

IDLgrShader:: SetProperty

The IDLgrShader::SetProperty procedure method sets the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShader::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrShader Properties](#)” on page 4337 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced
-----	------------

IDLgrShader::SetUniformVariable

The `IDLgrShader::SetUniformVariable` procedure method assigns a value to a named uniform variable. A uniform variable provides a way to pass small amounts of data to a shader program. It can enable interactivity by linking user interface control changes to shader program updates.

IDL stores the *Name* and *Value* of the uniform variable with the instance of the associated `IDLgrShader` object the first time this method is called. When `SetUniformVariable` is called again using the same *Name* argument, the uniform variable is updated with the current contents of *Value*. Once a uniform variable is associated with a shader object, there is no way to remove the reference. Any uniform variable that is defined, but not used in the shader program is simply ignored.

Note

For information about uniform variables, see “[Uniform Variables](#)” (Chapter 14, *Object Programming*).

The fragment shader program will support a minimum of 64 uniform variables (use `IDLgrWindow::GetDeviceInfo` to determine the exact number). For maximum shader program portability, define 64 or fewer variables.

In the case of a shader object associated with an `IDLgrImage`, or an `IDLgrPolygon` or `IDLgrSurface` with an associated `TEXTURE_MAP` image, you do not need to use `SetUniformVariable` to pass the image data to the shader program if multi-texturing is not occurring. The reserved uniform variable, `_IDL_ImageTexture`, automatically contains the texture map data associated with the primary `IDLgrImage` object. See “[Reserved Uniform Variables](#)” (Chapter 14, *Object Programming*) for details.

Note

If a shader object is associated with more than a single graphic object, any changes to a uniform variable will be applied to all associated objects. To avoid this, copy and associate an individual instance of a shader object with each individual graphic objects.

Syntax

Obj->[`IDLgrShader::SetUniformVariable`, *Name*, *Value*]

Arguments

Name

Specifies a case-sensitive string name of the uniform variable.

Value

Defines an IDL simple scalar value, array or an `IDLgrImage` object reference to be associated with *Name*. IDL strings, structures, pointers, and undefined variables are not allowed and will cause an error that halts execution. IDL converts all integer types to 32-bit long and converts all floating types to 32-bit float before submitting the data to the shader program.

If this argument is set to a 1-D or 2-D `IDLgrImage` object reference (the only type of object reference permitted), IDL loads the image data into an OpenGL texture that can be accessed using the uniform variable specified. This uniform variable must be defined as GLSL type *sampler1D* or *sampler2D* in the shader program.

If the dimensions of the `IDLgrImage` are not a power of 2 then the image will be padded to the next largest power of 2. If the dimensions of the `IDLgrImage` are larger than `MAX_TEXTURE_DIMENSIONS` (returned by `GetDeviceInfo`) then the image will be scaled down to `MAX_TEXTURE_DIMENSIONS`. Keep this in mind when generating texture coordinates to access the texture map. The `IDLgrImage` passed to `SetUniformVariable` cannot be tiled.

Keywords

None.

[IDLgrShader::GetUniformVariable](#)

IDLgrShaderBytscl

A shader byte-scale object is a subclass of `IDLgrShader` that can be associated with an `IDLgrImage` object via the `SHADER` property. This object lets you quickly perform a BYTSCL operation on the image data as it is drawn to the screen, taking advantage of the advanced processing power of the hardware-based OpenGL Shading Language (GLSL) if an appropriate graphics card is available. See “[Hardware Requirements for Shaders](#)” (Chapter 14, *Object Programming*) for details. Otherwise, this object performs the byte-scale operation using a software-based alternative. See Chapter 14, “[Advanced Rendering Using Shader Objects](#)” (*Object Programming*) for more information about shader objects.

Use the `IN_RANGE` and `OUT_RANGE` property values to control the byte-scaling parameters, which can be independently applied to each channel of image data. This object performs the byte-scaling operation in floating-point format and does not call the IDL BYTSCL function.

If the image data is other than byte or 8-bits per channel, set the `IDLgrImage` `INTERNAL_DATA_TYPE` property to avoid having your data truncated to byte.

Warning

Setting `IDLgrImage` `RENDER_METHOD=1` (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrshaderbytscl__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

[IDLgrShader](#)

Creation

See `IDLgrShaderBytscl::Init`.

Properties

Objects of this class have the following properties. See “[IDLgrShaderBytscl Properties](#)” on page 4356 for details on individual properties.

- [IN_RANGE](#)
- [OUT_RANGE](#)
- [UNITS_IN_RANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrShaderBytscl::Cleanup](#)
- [IDLgrShaderBytscl::GetProperty](#)
- [IDLgrShaderBytscl::Init](#)
- [IDLgrShaderBytscl::SetProperty](#)

In addition, this class inherits the methods of its superclass ([IDLgrShader](#)).

Examples

The following example creates an object that inherits from the `IDLgrShaderBytscl` object, loads grayscale image data and lets you interactively adjust the input and output data ranges using two sliders. Note that when using the `IDLgrShaderBytscl` object with non-byte data, you should set the `IDLgrImage` `INTERNAL_DATA_TYPE` property to avoid having your data truncated to a byte (0-255) range.

Example Code

See `shader_bytscl_doc__define.pro` for the complete, working example, which is located in the `examples/doc/shaders` subdirectory of the IDL distribution. Run the example by creating an instance of the object at the IDL command prompt using `obytsclshader=OBJ_NEW("shader_bytscl_doc")` or view the file in an IDL Editor window by entering `shader_bytscl_doc__define.pro`.

IDLgrShaderBytscl Properties

IDLgrShaderBytscl objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [“IDLgrShaderBytscl::GetProperty”](#) on page 4360. Properties with the word “Yes” in the “Init” column of the property table can be set via [“IDLgrShaderBytscl::Init”](#) on page 4361. Properties with the word “Yes” in the “Set” column in the property table can be set via [“IDLgrShaderBytscl::SetProperty”](#) on page 4363.

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [IN_RANGE](#)
- [OUT_RANGE](#)
- [UNITS_IN_RANGE](#)

In addition, objects of this class inherit the properties of:

- [“IDLgrShader”](#) on page 4335

IN_RANGE

A $2 \times n$ floating-point array that describes the MIN and MAX values for the byte-scaling operation for each of the n channels in the input image. See the [BYTSCL](#) function for more detail. See the [UNITS_IN_RANGE](#) property for this object to determine the units and scaling to use for setting this property.

Since the [IDLgrShader::Filter](#) method receives RGBA data from IDL, this object expands this property into a [2,4] floating-point array. The [UNITS_IN_RANGE](#) property value determines how incoming values are scaled before being expanded as follows:

- [a,b] — expands to [[a,b],[a,b],[a,b],[0,1]] (single LUM channel repeated in RGB, Alpha channel set to full range)
- [[a,b],[c,d]] expands to [[a,b],[a,b],[a,b],[c,d]] (LUM with Alpha channel specified)
- [[a,b],[c,d],[e,f]] expands to [[a,b],[c,d],[e,f],[0,1]] (RGB copied exactly, Alpha channel set to full range)

- `[[a,b],[c,d],[e,f],[g,h]]` expands to `[[a,b],[c,d],[e,f],[g,h]]` (entire range is specified)

The default values are `[0.0, 1.0]` for each channel. In all cases, the MAX value must be greater than the MIN value.

Property Type	Float array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OUT_RANGE

A $2 \times n$ floating-point array that describes the bottom and top range values for the output of the byte-scaling operation for each of the n channels in the image data. The top value corresponds to the TOP keyword used in the IDL `BYTSCL` function. For example, if the provided values are `[40,80]`, the data will be scaled into byte data in the range 40 - 80, inclusive. For compatibility with the IDL `BYTSCL` function, the minimum and maximum values for this property should be specified in the range `[0, 255]`.

Since the `IDLgrShader::Filter` method returns RGBA data to IDL, this object expands this property into a `[2,4]` floating-point array as follows:

- `[a,b]` — expands to `[[a,b],[a,b],[a,b],[0,1]]` (single LUM channel repeated in RGB, Alpha channel set to full range)
- `[[a,b],[c,d]]` expands to `[[a,b],[a,b],[a,b],[c,d]]` (LUM with Alpha channel specified)
- `[[a,b],[c,d],[e,f]]` expands to `[[a,b],[c,d],[e,f],[0,1]]` (RGB copied exactly, Alpha channel set to full range)
- `[[a,b],[c,d],[e,f],[g,h]]` expands to `[[a,b],[c,d],[e,f],[g,h]]` (entire range is specified)

Before performing the byte-scaling operation, these values are scaled into the floating-point range `[0,1]`.

The default values are `[0,255]` for each color channel and `[0,1]` for the alpha channel.

Property Type	Float array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UNITS_IN_RANGE

A scalar integer that represents the units used to express the minimum and maximum values specified by the `IN_RANGE` property. This value usually corresponds to the data type of the data stored in the image object. The allowed values, which correspond to IDL *type codes*, are:

Value (type code)	Data Units	IN_RANGE Values must be in this range:
0	Normalized	<ul style="list-style-type: none"> • [0.0, 1.0] for BYTE and UINT • [-1.0, 1.0] for INT • Any range for FLOAT.
1	BYTE	[0, 255]
2	INT	[-32768, 32767]
4	FLOAT	Any floating-point range
12	UINT	[0, 65535]

The default value is 0.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: No	Registered: No

IDLgrShaderBytscl::Cleanup

The IDLgrShaderBytscl::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

IDLgrShaderBytscl::GetProperty

The IDLgrShaderBytscl::GetProperty procedure method returns the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderBytscl::]GetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrShaderBytscl Properties](#)” on page 4356 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.4	Introduced
-----	------------

IDLgrShaderBytscl::Init

The IDLgrShaderBytscl::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrShaderBytscl' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrShaderBytscl::]Init([, *PROPERTY=value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None.

Keywords

Any property listed under “IDLgrShaderBytscl Properties” on page 4356 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced
-----	------------

IDLgrShaderBytscl:: SetProperty

The IDLgrShaderBytscl::SetProperty procedure method sets the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderBytscl::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrShaderBytscl Properties” on page 4356 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced
-----	------------

IDLgrShaderConvolve3

A convolution shader object is a subclass of IDLgrShader that can be associated with an IDLgrImage object via the **SHADER** property to perform general 3x3 convolution operations such as smoothing and edge detection on the image data as it is drawn to the screen. If hardware shader support is available, IDL will use it. Otherwise, this object performs the operation using a software-based alternative.

IDLgrShaderConvolve3 performs the convolution operation on each channel independently, using either a predefined convolution **KERNEL** or a user-specified kernel.

Since the hardware shader programs require data in floating-point format, this function converts the input data into the floating-point range of [0,1], applies the scaling, and then maps the scaled data into the device's output range.

The reserved uniform variable `_IDL_ImageStep` is set by the IDLgrImage object before calling the shader program. This GLSL type `vec2` variable contains the texture coordinate offsets needed to locate adjacent texels in both the *x* and *y* dimensions. These offsets are useful to shader programs that implement convolution kernels because it is necessary to use neighboring texels in these computations. See “[Reserved Uniform Variables](#)” (Chapter 14, *Object Programming*) for more information about reserved uniform variables.

Warning

Setting IDLgrImage **RENDER_METHOD**=1 (do *not* render image as texture-mapped polygon) disables all shader functionality including the software-based alternative.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgshaderconvolve3__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

[IDLgrShader](#)

Creation

See [IDLgrShaderConvolve3::Init](#).

Properties

Objects of this class have the following properties. See “[IDLgrShaderConvolve3 Properties](#)” on page 4367 for details on individual properties.

- [BASE_BLEND_FACTOR](#)
- [CONVOL_BLEND_FACTOR](#)
- [KERNEL](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrShaderConvolve3::Cleanup](#)
- [IDLgrShaderConvolve3::GetProperty](#)
- [IDLgrShaderConvolve3::Init](#)
- [IDLgrShaderConvolve3::SetProperty](#)

In addition, this class inherits the methods of its superclass ([IDLgrShader](#)).

Examples

The following example creates four instances of the `IDLgrShaderConvolve3` object and lets you apply one or more shaders to an image by modifying the `IDLgrFilterChain` object. See “[Filter Chain Shaders](#)” (Chapter 14, *Object Programming*) for more information about the `IDLgrShaderConvolve3` object and this example.

Example Code

See `shader_filterchain_doc_define.pro` for the complete, working example, which is located in the `examples/doc/shaders` subdirectory of the IDL distribution. Run the example by creating entering `o=OBJ_NEW('shader_filterchain_doc')` at the IDL command prompt or view the file in an IDL Editor window by entering `.edit shader_filterchain_doc_define.pro`.

IDLgrShaderConvolve3 Properties

IDLgrShaderConvolve3 objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrShaderConvolve3::GetProperty](#).

Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrShaderConvolve3::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrShaderConvolve3::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [BASE_BLEND_FACTOR](#)
- [CONVOLVE_BLEND_FACTOR](#)
- [KERNEL](#)

In addition, objects of this class inherit the properties of [“IDLgrShader”](#) on page 4335.

BASE_BLEND_FACTOR

A scalar single-precision floating-point value in the range of [0.0, 1.0] with a default value of 0.0. Setting this property to a numeric value outside of this range results in an error. This property controls the amount of the base image that is added to the kernel output, controlled by the [CONVOLVE_BLEND_FACTOR](#) property, in the final resulting image. The default value of 0.0 implies that no part of the base image is added to the final image.

Note

Some convolution kernels work best when combining the kernel output with the original base image. The sharpen convolution kernel ([KERNEL=2](#)) is a good example. The default value of 0.0, causes no contribution of the base image with the kernel output, while a value of 1.0 adds all of the base image to the kernel output.

Property Type	Float		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONVOL_BLEND_FACTOR

A scalar single-precision floating-point value in the range [0.0, 1.0]. This property controls the amount of the convolution kernel output that is added to the base image, controlled by the `BASE_BLEND_FACTOR` property, in the final resulting image. Setting this property to a numeric value outside of the 0.0 to 1.0 range results in an error. The default value is 1.0, which implies that all of the convolution output is added to the final image.

Property Type	Float		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

KERNEL

Either a scalar integer value indicating a pre-defined kernel, or a 9-element numerical array (that will be converted to a 3x3 floating-point array) containing a custom kernel. The predefined kernels are:

Value	Description
0	Identity (performs no operation on the image) - the default
1	Smooth
2	Sharpen
3	Edge Detection (vertical and horizontal)

The default value, 0, selects the “identity” kernel, which passes the image through without modification. This property may also be set with a 9-element numeric array. IDL converts this array to single-precision floating-point. Setting this property with any value other than a pre-defined kernel or a 9-element numeric array results in an error.

If this property is set with a scalar integer, `GetProperty` returns the same scalar integer. If this property is set with a 9-element numeric array, `GetProperty` returns a 9-element floating-point array.

Property Type	Integer or Array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrShaderConvolve3::Cleanup

The IDLgrShaderConvolve3::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrShaderConvolve3::]Cleanup (In a lifecycle method only.)

IDLgrShaderConvolve3::Init

The IDLgrShaderConvolve3::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrShaderConvolve3' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrShaderConvolve3::]Init([, *PROPERTY=value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None.

Keywords

Any property listed under “IDLgrShaderConvolve3 Properties” on page 4367 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.4	Introduced
-----	------------

IDLgrShaderConvolve3::SetProperty

The IDLgrShaderConvolve3::SetProperty procedure method sets the value of a property or group of properties for the shader.

Syntax

Obj->[IDLgrShaderConvolve3::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrShaderConvolve3 Properties](#)” on page 4367 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLgrSurface

A surface object represents a shaded or vector representation of a mesh grid.

An IDLgrSurface object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrSurface::Init](#)” on page 4414.

Properties

Objects of this class have the following properties. See “[IDLgrSurface Properties](#)” on page 4378 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DATA_X](#)
- [DATA_Y](#)
- [DATA_Z](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)
- [DIFFUSE](#)
- [DOUBLE](#)
- [EMISSION](#)
- [EXTENDED_LEGO](#)
- [HIDDEN_LINES](#)
- [HIDE](#)
- [LINESYLE](#)
- [MAX_VALUE](#)
- [MIN_VALUE](#)
- [PALETTE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RESET_DATA](#)
- [SHADE_RANGE](#)

- SHADER
- SHARE_DATA
- SHOW_SKIRT
- SPECULAR
- TEXTURE_COORD
- TEXTURE_INTERP
- THICK
- VERT_COLORS
- XRANGE
- YRANGE
- ZERO_OPACITY_SKIP
- SHADING
- SHININESS
- SKIRT
- STYLE
- TEXTURE_HIGHRES
- TEXTURE_MAP
- USE_TRIANGLES
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrSurface::Cleanup`
- `IDLgrSurface::GetCTM`
- `IDLgrSurface::GetMultiTextureCoord`
- `IDLgrSurface::GetProperty`
- `IDLgrSurface::GetVertexAttributeData`
- `IDLgrSurface::Init`
- `IDLgrSurface::SetProperty`
- `IDLgrSurface::SetMultiTextureCoord`
- `IDLgrSurface::SetVertexAttributeData`

In addition, this class inherits the methods of its superclasses (if any).

Examples

See [“Mapping an Image onto Elevation Data”](#) (Chapter 3, *Image Processing in IDL*) for a texture mapping example and [Chapter 6, “Working with Surface Objects”](#) (*Object Programming*) for additional examples.

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property
6.1	Added ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, and SPECULAR properties
6.4	Added SHADER property Added GetVertexAttributeData, SetVertexAttributeData, GetMultiTextureCoord, and SetMultiTextureCoord methods

IDLgrSurface Properties

IDLgrSurface objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrSurface::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrSurface::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrSurface::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOTTOM](#)
- [CLIP_PLANES](#)
- [COLOR](#)
- [DATA](#)
- [DATA_X](#)
- [DATA_Y](#)
- [DATA_Z](#)
- [DEPTH_OFFSET](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_TEST_FUNCTION](#)
- [DEPTH_WRITE_DISABLE](#)

In addition, objects of this class inherit:

- IDLitComponent

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the surface. The default value of 1.0 causes IDL to draw the surface completely opaque. If the value of this property is less than 1.0, then the pixels of the surface are blended with the pixels already on the screen. The color of the surface is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results. This also applies to the individual facets of the surface that IDL generates to represent the surface geometry. Since you do not have control over the rendering order of the facets that form the surface, there is little you can do to change

the ordering so that the facets draw in a back-to-front order. Therefore, using this property to draw semi-transparent surfaces is not recommended unless the surface geometry and orientation is such that the surface can be viewed without self-overlapping areas.

This property has no effect on devices using indexed color mode.

When used with textures, the ALPHA_CHANNEL value controls the opacity of the polygon in the same manner as when not using a texture. If the texture contains alpha information, the effective alpha of each texel is the texel's alpha multiplied by the polygon's alpha value (ALPHA_CHANNEL property).

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AMBIENT

Set this property to a three-element vector [*red, green, blue*] to specify the ambient reflective color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the ambient reflective color of the object. Setting an ambient color other than black makes the object use that color for ambient reflectance. Ambient reflectance affects the overall color of the object and is most noticeable where the object is not directly lit by a light source. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Ambient reflective color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BOTTOM

A scalar or three-element vector [*red, green, blue*] specifying the color used to draw the bottom of the surface. Set this property to a scalar to draw the bottom with the same color as the top. If set to a scalar, IDL returns the default value of -1 if the

property is retrieved with `GetProperty`. Setting a bottom color is only supported when the destination device uses RGB color mode.

Property Type	COLOR		
Name String	Bottom color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form $[A, B, C, D]$, where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the `IDLgrView` in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the `MAX_NUM_CLIP_PLANES` property of the `GetDeviceInfo` method for the `IDLgrBuffer`, `IDLgrClipboard`, `IDLgrWindow`, and `IDLgrVRML` objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for this model. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default is $[0, 0, 0]$.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA

An array of any type that specifies the surface data. The array format is based upon the following:

- If the DATAZ property (or Data argument) was set to an $M \times N$ array (via the `::Init` or `::SetProperty` methods), then the value returned via the DATA property is a $3 \times M \times N$ array, `[[[x,y,z],[x,y,z],...],[[x,y,z],[x,y,z],...],...]`.
- If the DATAZ keyword (or Data argument) was never set, then the value returned via the DATA property is an undefined variable.

The value of the DATA array represents the combination of the DATAZ, DATAX, DATAY, and DATAZ values defined using `::SetProperty`. If DATAZ was set, and DATAX and DATAY were not, the DATA value returned includes the implied X and Y grid locations.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DATAX

A floating-point vector or a two-dimensional array specifying the X coordinates of the surface grid. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Specifying this property is the same as specifying the optional X argument to the [IDLgrSurface::Init](#) method.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAY

A floating-point vector or a two-dimensional array specifying the Y coordinates of the surface grid. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Specifying this property is the same as specifying the optional Y argument to the [IDLgrSurface::Init](#) method.

Property Type	Floating-point vector or array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DATAZ

A two-dimensional floating-point array to display as a surface. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Specifying this property is the same as specifying the optional Z argument to the [IDLgrSurface::Init](#) method.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

Note

Use this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple `DEPTH_OFFSET` values. It is safest to use only a `DEPTH_OFFSET` value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of `DEPTH_OFFSET` values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of `DEPTH_OFFSET` values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use `DEPTH_OFFSET`.

Note

`DEPTH_OFFSET` has no effect unless the value of the `STYLE` property is 2 or 6 (Filled or LegoFilled).

Property Type	INTEGER		
Name String	Depth offset		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see DEPTH_TEST_DISABLE property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DIFFUSE

Set this property to a three-element vector [*red, green, blue*] to specify the diffuse reflectance color of the object. The default is black or [0,0,0], which specifies that the value of the COLOR property determines the diffuse reflective color of the object. Setting a diffuse color other than black makes the object use that color for diffuse reflectance. Diffuse reflectance is an important factor in determining the color of the object and is affected by the color and angle of the light sources in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Diffuse reflective color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

EMISSION

Set this property to a three-element vector [*red, green, blue*] to specify the emissive color of the object. The default is black or [0,0,0], which specifies that the object contributes no additional color in an emissive sense. Setting an emission color other than black makes the object appear as if it were emitting that color. This property is used to simulate light sources or other objects that emit light in a scene. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Emissive color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EXTENDED_LEGO

A Boolean value that determines whether to force the IDLgrSurface object to display the last row and column of data when lego display styles are selected.

Property Type	Boolean		
Name String	Show last lego row/column		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

Property Type	Boolean		
Name String	Remove hidden lines		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do no draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LINestyle

An integer value that indicates the line style to use to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set this property equal to one of the following integer values:

0	Solid line (the default)
1	Dotted
2	Dashed
3	Dash dot
4	Dash dot dot dot
5	Long dash
6	No line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq \textit{repeat} \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINestyle = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:

Property Type	Linestyle		
Name String	Line style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. If this property is present, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Maximum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Minimum value		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrSurface object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XYZ] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data

with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via a DATA[XYZ] property. .

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color element for the brightest pixel. This value is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the surface is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional surface objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADING

An integer value or enumerated list item representing the type of shading to use if STYLE is set to 2 (Filled).

Value	Property Sheet Value	Description
0	Flat	The color has a constant intensity for each face of the surface, based on the normal vector (the default)
1	Gouraud	The colors are interpolated between vertices, and then along scanlines from each of the edge intensities

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

Property Type	ENUMLIST		
Name String	Fill shading		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHARE_DATA

An object reference to an object whose data is to be shared by this surface. A surface may only share data with another surface. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrSurface object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

SHININESS

Set this property to a floating-point value between 0.0 and 128.0, inclusive. The default value is 25.0. Higher values of shininess concentrate specular highlights into smaller and brighter areas, while lower values will spread out specular highlights over a wider area and make them appear dimmer.

Property Type	FLOAT		
Name String	<i>Shininess</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHOW_SKIRT

A Boolean value that determines whether to enable skirt drawing. The default is to disable skirt drawing. .

Property Type	Boolean		
Name String	Show skirt		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SKIRT

A floating-point value that determines the *Z* value at which a skirt is to be defined around the array. The *Z* value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given *Z* value, and the same *X* and *Y* values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is ignored if skirt drawing is disabled (see `SHOW_SKIRT` above). IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Skirt bottom height		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SPECULAR

Set this property to a three-element vector [*red*, *green*, *blue*] to specify the color of the specular highlights of an object. The default is white or [255,255,255]. This

property is used to simulate and control reflective highlights on an object. This property has no effect on devices using indexed color mode.

Property Type	COLOR		
Name String	<i>Specular highlight color</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

STYLE

An integer value or an enumerated list item that indicates the style to be used to draw the surface. Valid values are:

Value	Property Sheet Value	Description
0	Points	Points
1	Wire mesh	Wire mesh (the default)
2	Filled	Filled
3	RuledXZ	RuledXZ
4	RuledYZ	RuledYZ
5	Lego	Lego
6	Lego filled	Lego filled for outline or shaded and stacked histogram-style plots

Note

Stitching effects may appear when combining an unfilled style (STYLE=0, 1, 3, 4, or 5) and hidden lines (HIDDEN_LINES=1). In such a case, missing lines may be caused by depth buffer resolution, limited depth offset support of the graphics card, or invisible parts of a surface occluding line visibility.

Property Type	ENUMLIST		
Name String	Surface style		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_COORD

A 2-by- n floating-point array of texture map coordinate pairs that are internally mapped to surface vertex coordinates. The number of data points in the surface and the value of n in the 2-by- n array should be equal.

Each texture map coordinate pair is mapped to a surface vertex coordinate pair in array order. For example, with a 2-by-9 element array, texture map coordinates will be mapped to a 3-by-3 surface as follows:

Figure 31-10: Mapping Texture Coordinates

Use this property in conjunction with the TEXTURE_MAP property to warp images over the surface. To stretch (or shrink) the texture map to cover the surface mesh completely, set TEXTURE_COORD to a scalar. By default, IDL stretches (or shrinks) the texture map to cover the surface mesh completely, and sets TEXTURE_COORD to a scalar (-1).

Texture coordinates are normalized. This means that the $m \times n$ image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. As the texture coordinates run from 0.0 to 1.0 across a texture, a texture coordinate of [0.5, 0.5] at a vertex specifies that the image pixel at the exact center of the image is mapped to the surface at that vertex. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a surface two units on each side. To completely fill the 2 x 2 surface with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [0,1], [1,1]]
```

To fill the 2 x 2 surface with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [0,2], [2,2]]
```

Because of the way in which high-resolution textures require modified texture coordinates, if the TEXTURE_COORD property is used, TEXTURE_HIGHRES will be disabled.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TEXTURE_HIGHRES

An integer value or enumerated list item that determines the type of texture tiling, if any, that will be used to maintain the full pixel resolution of the original texture image.

Value	Property Sheet Value	Description
0	No tiling	If the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to this resolution (the default).
1	LOD tiling	<p>If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. As a large image could easily consume all available video memory, this mode employs texture Level of Detail (LoD). Rather than loading the entire image into the texture tiles at the full resolution, the image tiles are downsampled based on the level of zoom. If the entire image is visible the texture tiles will contain highly downsampled data from the image to conserve video memory. As a portion of the image is zoomed in on, progressively higher resolution image data is loaded into the visible tiles, until the maximum resolution is reached. The tiles that are not visible during zooming are not loaded with high resolution data.</p> <p>Note - This mode is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic when TEXTURE_HIGHRES=0.</p>
2	Tiling	If the texture map is larger than the maximum resolution supported by the hardware, texture tiling is used to ensure no loss of data. However, the highest resolution data is loaded into all tiles. LoD tiling is disabled. This mode should only be used if the video memory is sufficient for the image size.

Note

TEXTURE_HIGHRES is supported only when [STYLE=2](#) (Filled).

Note

Because of the way in which high-resolution textures require modified texture coordinates, if you specify the TEXTURE_COORD property, high resolution textures (TEXTURE_HIGHRES) will be disabled.

Property Type	ENUMLIST		
Name String	Texture hires		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_INTERP

A Boolean value or enumerated list item that indicates whether bilinear sampling is to be used with texture mapping.

Value	Property Sheet Value	Description
0	Nearest neighbor	Surveys the value of the nearest pixel (the default)
1	Bilinear	Surveys the 4 closest pixels

Note

See [“Interpolation Methods”](#) (Chapter 5, *Using IDL*) for details.

Property Type	ENUMLIST		
Name String	Texture interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TEXTURE_MAP

An object reference to an instance of the [IDLgrImage](#) object class to be texture mapped onto the surface. If this property is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or

VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) By default, the texture map will be stretched (or shrunk) to cover the surface mesh completely.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrSurface object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function $src = alpha$ and $dst = 1 - alpha$, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If a texture is provided without texture coordinates, IDLgrSurface generates its own texture mapping coordinates to map the texture onto the surface without resampling artifacts, even if the provided texture image does not have dimensions that are an exact power of two. If texture coordinates are provided, the image is resampled to the nearest larger dimensions that are exact powers of two.

Note

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

Note

Texture mapping is applied to all styles that are set by the STYLE property except Lego and LegoFilled.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrSurface object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Texture map		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

In a property sheet, this property appears as follows:

Property Type	Thickness		
Name String	Line thickness		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

USE_TRIANGLES

A Boolean value or an enumerated list item that determines whether to force the IDLgrSurface object to use triangles instead of quads to draw the surface and skirt.

Value	Property Sheet Value	Description
0	Quads	Use quads to draw the surface and skirt (the default)
1	Triangles	Use triangles to draw the surface and skirt

Property Type	Boolean		
Name String	Draw method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERT_COLORS

A vector of colors to be used to specify the color of a surface vertex. The vector may be of the form $[n]$ where each entry is a color index, or of the form $[3,n]$ where each 3-element row is an RGB color, or of the form $[4,n]$ where each 4-element row is an RGBA color. To remove vertex colors after they have been set, set VERT_COLORS to a scalar.

If VERT_COLORS is not specified, the entire surface is drawn in the single color provided by the COLOR property, which is the default action.

If SHADING is set to 0 (Flat, the default) the color of a surface polygon is the color of the first vertex of that surface polygon. Color is interpolated between vertices if SHADING is set to 1 (Gouraud).

If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated.

Note

If the surface object is being rendered on a destination device that uses the Indexed color model, and the view that contains the surface also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Vertex colors		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[x_{min}, x_{max}]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized } Y = s_0 + s_1 * \text{Data } Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[y_{min}, y_{max}]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that determines whether to gain finer control over the rendering of textured surface pixels (texels) by setting an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this property is set to 1, any texels are “skipped” and not rendered at all. If this property is set to zero, the Z -buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z -buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

Note

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

Property Type	Boolean		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrSurface::Cleanup

The IDLgrSurface::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrSurface::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrSurface::GetCTM

The IDLgrSurface::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrSurface::]GetCTM( [, DESTINATION=objref]  
[ , PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrSurface::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrSurface::GetMultiTextureCoord

The `IDLgrSurface::GetMultiTextureCoord` returns the texture coordinates associated with a given *Unit*. This method is useful when a shader program defined by an [IDLgrShader](#) object applies more than a single texture to an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

```
Obj->[IDLgrSurface::]GetMultiTextureCoord, Unit, TexCoord
```

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the `MAX_VERTEX_TEXTURE_IMAGE_UNITS` (for vertex shaders) or `MAX_TEXTURE_IMAGE_UNITS` (for fragment shaders). These values can be returned by [IDLgrWindow::GetDeviceInfo](#).

Note

If the specified *Unit* value was never defined and stored in the surface object using [IDLgrSurface::SetMultiTextureCoord](#), then the variable specified in the *TexCoord* parameter will be set to an undefined variable.

TexCoord

Specifies a variable that contains the current texture coordinates associated with the specified *Unit*. Texture coordinates are stored in this parameter as single precision floating point numbers.

Keywords

None

Examples

See “[Multi-texture Shaders](#)” (Chapter 14, *Object Programming*)

Version History

6.4	Introduced

[IDLgrSurface::SetMultiTextureCoord](#)

IDLgrSurface::GetProperty

The IDLgrSurface::GetProperty procedure method retrieves the value of a property or group of properties for the surface.

Syntax

Obj->[IDLgrSurface::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 4378 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrSurface::GetVertexAttributeData

The `IDLgrSurface::GetVertexAttributeData` procedure method retrieves the data associated with a named attribute variable containing per-vertex attribute data. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*). This method is useful when a shader program defined by an `IDLgrShader` object modifies the vertices of an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

Obj->[`IDLgrSurface::`]GetVertexAttributeData, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable to retrieve.

Note

If the *Name* argument specifies an attribute variable that was never defined and stored in the surface object using `SetVertexAttributeData`, then the variable specified in the *Value* parameter will be set to an undefined variable.

Value

Specifies a variable that contains the current value of the vertex data attribute variable. The variable is stored in this parameter in exactly the same format as that used when it was defined using `IDLgrSurface::SetVertexAttributeData`.

Keywords

None

Examples

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*).

Version History

6.4	Introduced
-----	------------

[IDLgrSurface::SetVertexAttributeData](#)

IDLgrSurface::Init

The IDLgrSurface::Init function method initializes the surface object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrSurface' [, Z [, X, Y]] [, PROPERTY=*value*])

or

Result = *Obj*->[IDLgrSurface::]Init([Z [, X, Y]] [, PROPERTY=*value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinates for a column of Z (e.g., X[0] specifies the X coordinate for Z[0, *]). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z (X_{ij} specifies the X coordinate of Z_{ij}). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

Note

The value specified by the *X* argument is used to initialize the value of the [DATA_X](#) property of the IDLgrSurface object.

Y

A vector or two-dimensional array specifying the *Y* coordinates of the grid. If this argument is a vector, each element of *Y* specifies the *Y* coordinates for a column of *Z* (e.g., *Y*[0] specifies the *Y* coordinate for *Z*[*, 0]). If *Y* is a two-dimensional array, each element of *Y* specifies the *Y* coordinate of the corresponding point in *Z* (*Y*_{*ij*} specifies the *Y* coordinate of *Z*_{*ij*}). This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is stored as single precision floating point.

Note

The value specified by the *Y* argument is used to initialize the value of the [DATA_Y](#) property of the IDLgrSurface object.

Z

The two-dimensional array to be displayed. If *X* and *Y* are provided, the surface is defined as a function of the (*X*, *Y*) locations specified by their contents. Otherwise, the surface is generated as a function of the array indices of each element of *Z*. This argument is stored as double precision floating point values if the argument variable is of type `DOUBLE` or if the `DOUBLE` property is non-zero, otherwise it is stored as single precision floating point.

Note

The value specified by the *Z* argument is used to initialize the value of the [DATA_Z](#) property of the IDLgrSurface object.

Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 4378 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrSurface:: SetProperty

The IDLgrSurface::SetProperty procedure method sets the value of a property or group of properties for the surface.

Syntax

Obj->[IDLgrSurface::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrSurface Properties](#)” on page 4378 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrSurface::SetMultiTextureCoord

The `IDLgrSurface::SetMultiTextureCoord` procedure method passes texture coordinates to a shader program when the shader program applies more than one texture to an object. The shader program accesses these texture coordinates by using the GLSL predefined uniform variable `gl_MultiTexCoordn`, where *n* corresponds to the *Unit* parameter in this method. This method is useful when a shader program defined by an `IDLgrShader` object applies more than a single texture to an object. See [Chapter 14, “Advanced Rendering Using Shader Objects”](#) (*Object Programming*) for more information.

Syntax

Obj->[`IDLgrSurface::`]SetMultiTextureCoord, *Unit*, *TexCoord*

Arguments

Unit

This scalar numeric value specifies the texture unit. Texture units are used primarily with multi-texturing and allow OpenGL to handle multiple textures and multiple sets of texture coordinates and parameters. This value should be greater than or equal to zero and less than the `MAX_VERTEX_TEXTURE_IMAGE_UNITS` (for vertex shaders) or `MAX_TEXTURE_IMAGE_UNITS` (for fragment shaders). These values can be returned by `IDLgrWindow::GetDeviceInfo`. The behavior is undefined for any other setting.

Unit 0 is used by the `TEXTURE_COORD` property on `IDLgrSurface`. Using unit 0 in this method overrides any texture coordinates specified with the `TEXTURE_COORD` property. Therefore, the `TEXTURE_COORD` property can be used instead of this method if *Unit* is 0.

TexCoord

This data has exactly the same form as the `TEXTURE_COORD` property. IDL converts and maintains this data as single precision floating point. IDL displays an error message and does not draw the object if the number of texture coordinates provided in this parameter is not the same as the number of vertices in the surface.

IDL stores the texture coordinates in the instance of the graphic object when the application calls this method for the first time with a given *Unit* parameter. If the application calls this method again with a *Unit* number used in a previous call to this

method, IDL replaces the corresponding stored texture coordinates with the contents of the *TexCoord* parameter.

There is no way to remove texture coordinates from an instance of a graphics object. If texture coordinates are associated with a particular texture unit, and the shader program does not reference that unit, the texture coordinates are effectively ignored by the shader program.

Keywords

None

Examples

See “[Multi-texture Shaders](#)” (Chapter 14, *Object Programming*)

Version History

6.4	Introduced

[IDLgrSurface::GetMultiTextureCoord](#)

IDLgrSurface::SetVertexAttributeData

The `IDLgrSurface::SetVertexAttributeData` procedure method passes a set of per-vertex attribute data to a vertex shader program. When an `IDLgrShader` object is associated with the surface via the `SHADER` property, this attribute data is made available, a vertex's worth at a time, to the vertex shader program as it processes each vertex in the surface. If there are more vertices in the surface than there are vertex attributes, the list of vertex attributes is reused until all the vertices are drawn. See “[Attribute Variables](#)” (Chapter 14, *Object Programming*) for a general introduction to attribute variables. Also see the chapter, “[Advanced Rendering Using Shader Objects](#)” (*Object Programming*) for additional shader program information and examples.

IDL stores the *Name* and *Value* of the vertex attribute data variable with this surface object the first time this method is called. When `SetVertexAttributeData` is called again using the same *Name* argument, the vertex attribute data variable is updated with the current contents of *Value*. Once a vertex attribute data variable is associated with this object, there is no way to remove the reference. The shader program ignores any vertex attribute data variable defined for this object but not declared in the shader program.

The attribute data may consist of 1 to 4 elements per vertex. The data is passed to the vertex shader program via a shader program variable with the attribute qualifier. The attribute variable may be of GLSL type `float`, `vec2`, `vec3`, `vec4`, `mat2`, `mat3`, or `mat4`. Internally, the `mat2` type is treated as two `vec2` attribute variables, `mat3` as three `vec3` attribute variables, and `mat4` as four `vec4` attribute variables.

If the attribute variable is larger than the data passed to it, the shader program pads the missing elements as follows. A missing second or third element is set to 0.0. A missing fourth element is set to 1.0.

For example, the IDL application has a set of vertex attribute data where there is an x-offset and a y-offset for each vertex. The vertex program defines an attribute variable using a `vec4` type so that it can be used in 4x4 general transformations. The IDL program stores the x- and y-offset information in a `[2, n]` array and sets the value of the attribute variable to this array. As the shader program runs, for each vertex it assigns the two values from the corresponding row of the IDL array to the first two elements in the `vec4` attribute variable. It also sets the third value to 0.0 and the fourth value to 1.0, thus expanding the 2-element data to a general 3-D point in homogenous coordinate space, suited for 4x4 general transforms.

Note

A minimum of 16 vertex attribute data variables can be passed to the shader vertex program (use `IDLgrWindow::GetDeviceInfo` to determine the exact number). IDL

uses one vertex attribute variable, leaving the remainder for user programs. For maximum shader program portability, define 15 or fewer attribute variables.

Syntax

Obj->[IDLgrSurface::]SetVertexAttributeData, *Name*, *Value*

Arguments

Name

Specifies a case-sensitive string name of the attribute variable.

Value

Specifies an IDL array of any numeric type. The array must be of the form $[n]$, $[a,n]$, or $[a,a,n]$ where a is 1,2,3, or 4 and n is the number of vertex attribute elements. IDL will halt with an error if you assign IDL strings, structures, pointers, object references, and undefined variables to *Value*. IDL converts all numeric types to 32-bit float when submitting the data to the shader program.

Keywords

None

Examples

Suppose there is large set of point sample data, along with a set of initial velocity vectors for each point. You want to display an animation of these points as each point moves along its own velocity vector as a function of time. Without a shader program, you would normally have to recalculate the position of each point and replace all the vertices in an IDLgrPolygon (*STYLE=0*) object with the recomputed values for each animation frame, which would be inefficient with a large number of points.

However, with a vertex shader program and vertex attribute data, you can move the points around using the graphics card's GPU instead of recalculating and moving a lot of data around on the system CPU.

The interesting parts of the IDL code are:

```
; Define the original vertices at time=0.  
oPolygon->SetProperty, DATA=vertices
```

```

; Set [3,n] array.
oPolygon->SetVertexAttributeData, 'velocity', velocities
FOR t=0.0, 100.0, 0.01 DO BEGIN ;; time samples
    oShader->SetUniformVariable, 'time', t
    oWindow->Draw
ENDFOR

```

And the interesting parts of the vertex shader program are:

```

attribute vec3 velocity;
uniform float time;
void main () {
    vec4 vert;
    vert = gl_Vertex + vec4(velocity * time, 0.0);
    gl_Position = gl_ModelViewProjectMatrix * vert;
}

```

See “[Vertex Shaders](#)” (Chapter 14, *Object Programming*) for more information and examples.

IDLgrSymbol

A symbol object represents a graphical element that is plotted relative to a particular position.

Note

Seven predefined symbols are provided by IDL.

Superclasses

None

Creation

See “[IDLgrSymbol::Init](#)” on page 4432.

Properties

Objects of this class have the following properties. See “[IDLgrSymbol Properties](#)” on page 4425 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [COLOR](#)
- [DATA](#)
- [NAME](#)
- [SIZE](#)
- [THICK](#)
- [UVALUE](#)

Methods

This class has the following methods:

- [IDLgrSymbol::Cleanup](#)
- [IDLgrSymbol::GetProperty](#)
- [IDLgrSymbol::Init](#)

- [IDLgrSymbol:: SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
6.1	Added ALPHA_CHANNEL property
6.2	Added NAME and UVALUE properties

IDLgrSymbol Properties

IDLgrSymbol objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrSymbol::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrSymbol::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrSymbol::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [COLOR](#)
- [DATA](#)
- [NAME](#)
- [SIZE](#)
- [THICK](#)
- [UVALUE](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value in the range [0.0, 1.0] to specify the opacity of the symbol. The default value of 1.0 causes IDL to draw the symbol completely opaque. If the value of this property is less than 1.0, then the pixels of the symbol are blended with the pixels already on the screen, where the color of the symbol is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Some of the objects that use symbols have properties that control the alpha value that is ultimately used to render the symbol. This ultimate alpha value might come from the parent object's ALPHA_CHANNEL property, an alpha value from a vertex color in the parent object, or the value of this property, depending on the settings of properties in the parent object. Refer to the reference guide for the parent properties for information on these controls.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see [“Controlling Object Transparency”](#) (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color used to draw the symbol. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default color is the color of the object for which this symbol is being used.

Property Type	Color		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA

Either an integer value (from the following list), or an object reference to either an IDLgrModel object, or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond
- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = "Greater-than" Arrow Head (>)
- 9 = "Less-than" Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Specifying this property is the same as specifying the optional *Data* argument to the [IDLgrSymbol::Init](#) method.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrSymbol object is destroyed.

Property Type	Integer or object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SIZE

A one-, two-, or three-element floating-point vector describing the X, Y, and Z scaling factors to be applied to the symbol. The default is [1.0, 1.0, 1.0].

- If SIZE is specified as a scalar, then the X, Y, and Z scale factors are all equal to the scalar value.
- If SIZE is specified as a 2-element vector, then the X and Y scale factors are as specified by the vector, and the Z scale factor is 1.0.
- If SIZE is specified as a 3-element vector, then the X, Y, and Z scale factors are as specified by the vector.

IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to used to draw any lines that make up the symbol, in points. Out-of-range values are quietly clamped to the allowed range. The default is 1.0 points.

Property Type	Floating-point		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLgrSymbol object is destroyed.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLgrSymbol::Cleanup

The IDLgrSymbol::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrSymbol::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrSymbol::GetProperty

The IDLgrSymbol::GetProperty procedure method retrieves the value of a property or group of properties for the symbol.

Syntax

Obj->[\[IDLgrSymbol::\]GetProperty](#)[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrSymbol Properties](#)” on page 4425 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.0	Introduced
-----	------------

IDLgrSymbol::Init

The IDLgrSymbol::Init function method initializes the plot symbol.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrSymbol' [, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrSymbol::]Init([Data] [, PROPERTY=value]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

Either an integer value from the list shown below, or an object reference to either an IDLgrModel object or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = “Greater-than” Arrow Head (>)
- 9 = “Less-than” Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

Note

The value specified by the *Data* argument is used to initialize the value of the [DATA](#) property of the IDLgrSymbol object.

Keywords

Any property listed under “[IDLgrSymbol Properties](#)” on page 4425 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
5.6	Added <i>Data</i> argument

IDLgrSymbol:: SetProperty

The IDLgrSymbol::SetProperty procedure method sets the value of a property or group of properties for the symbol.

Syntax

Obj->[IDLgrSymbol::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrSymbol Properties](#)” on page 4425 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrTessellator

A tessellator object decomposes a polygon description into a set of triangles. Use the tessellator object to convert complex and/or concave polygons into a form suitable for drawing with the IDLgrPolygon object. IDLgrPolygon can draw only convex polygons correctly.

The polygon contours may intersect each other and may be self-intersecting. The contours may be disjoint, overlapping, or contained within other contours. The contours may also be degenerate, may contain repeated points, and may or may not be closed. The order of the vertices may be either counter-clockwise or clockwise. Tessellation may produce unexpected results if the input polygon contours are not coplanar, or if a contour is not planar.

The tessellator object uses the “odd-winding rule” to determine if a point is in the interior of the polygon and therefore contained in a triangle output by the tessellator. With this rule, a point is in the interior if it is circled an odd number of times as we travel around each of the contours.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

Specify polygon contours with calls to the [IDLgrTessellator::AddPolygon](#) method. After adding all the contours, use the IDLgrTessellator::Tessellate method to perform the tessellation and retrieve the resulting list of vertices and connectivity array.

If the polygon contours contain intersecting or self-intersecting contours, the tessellator may return vertices that were not in the original set of vertices specified with the [IDLgrTessellator::AddPolygon](#) method. These vertices are created by the intersecting contours.

If your vertex data also includes other information, such as a color for each vertex, then you may wish for this extra information to be created for any new vertices generated by the tessellator. Use the AUXDATA keywords for [IDLgrTessellator::AddPolygon](#) and [IDLgrTessellator::Tessellate](#) to pass in and retrieve your per-vertex data. The tessellator object interpolates the per-vertex data from neighboring vertices to create new per-vertex data for the new vertices it generates.

In the following example of handling per-vertex data with generated vertices, the polygon is a simple self-intersecting “bow-tie” polygon. It is submitted to the tessellator with four vertices, but the tessellator returns a fifth at the point of self-intersection. Color data for the four original vertices is also supplied, and the tessellator returns a fifth color.

```

PRO tessaux
  oTess = OBJ_NEW('IDLgrTessellator')
  colors = [[0,255,0],[0,255,0],[0,64,0],[0,64,0]]
  oTess->AddPolygon, [0,1,0,1], [0,0,1,1], AUXDATA=colors
  result = oTess->Tessellate(v, c, AUXDATA=aux)
  PRINT, v[*],4]
  PRINT, aux[*],4]
  oPoly = OBJ_NEW('IDLgrPolygon', v, POLYGONS=c, $
    VERT_COLORS=aux, SHADING=1)
  XOBJVIEW, oPoly, /BLOCK
  OBJ_DESTROY, [oTess, oPoly]
END

```

The generated output will be:

```

0.500000      0.500000
0      159      0

```

Superclasses

None

Creation

See “[IDLgrTessellator::Init](#)” on page 4443.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDLgrTessellator::AddPolygon](#)
- [IDLgrTessellator::Cleanup](#)
- [IDLgrTessellator::Init](#)
- [IDLgrTessellator::Reset](#)

- [IDLgrTessellator::Tessellate](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
-----	------------

IDLgrTessellator Properties

Objects of this class have no properties of their own.

IDLgrTessellator::AddPolygon

The IDLgrTessellator::AddPolygon procedure method adds a polygon to the tessellator object.

Syntax

Obj->[IDLgrTessellator:]AddPolygon, X [, Y[, Z]] [, **AUXDATA**=array of auxiliary data] [, **INTERIOR**] [, **POLYGON**=array of polygon descriptions]

Arguments

X

A $1 \times n$, $2 \times n$, or $3 \times n$ array of polygon vertices.

Y

A vector of Y values. If X and Y are both specified, they must be one-dimensional vectors of the same length.

Z

A vector of Z values. If X, Y, and Z are all specified, they must all three be one-dimensional vectors of the same length. If no Z values are specified, the Z value for the polygon is set to 0.

Keywords

AUXDATA

Set this keyword to an array of auxiliary per-vertex data. This array must have dimensions $[m,n]$ where m is the number of auxiliary data items per vertex and n is the number of vertices specified in the X, Y, and Z arguments. If you specify AUXDATA in any invocation of the AddPolygon method, you must specify it on all invocations of the method for the polygons to be tessellated together with the Tessellate method. Further, the value of m in the dimensions must be the same for all polygons. That is, all polygons must have the same number of auxiliary data items for each vertex.

INTERIOR

Set this keyword to set a polygon to be an interior polygon, which is treated as a hole in the exterior polygons.

Note

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

POLYGON

Set this keyword to an array of polygon descriptions. A polygon description is an integer or long word array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the X , Y , and Z arguments that represent the polygon vertices. To ignore an entry in the POLYGON array, set the vertex count, n , to 0. To end the drawing list, even if additional array space is available, set n to -1. If this keyword is not specified, a single polygon will be generated.

Note

The connectivity array described by POLYGONS allows you to add multiple polygons to the tessellator object with a single AddPolygon operation.

Version History

5.0	Introduced
5.6	Added AUXDATA keyword

IDLgrTessellator::Cleanup

The IDLgrTessellator::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY,Obj

or

Obj->[IDLgrTessellator::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrTessellator::Init

The IDLgrTessellator::Init function method initializes the tessellator object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrTessellator')
```

or

```
Result = Obj->[IDLgrTessellator::]Init() (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrTessellator::Reset

The IDLgrTessellator::Reset procedure method resets the object's internal state. All previously added polygons are removed from memory and the object is prepared for a new tessellation task.

Syntax

Obj->[IDLgrTessellator::Reset](#)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrTessellator::Tessellate

The IDLgrTessellator::Tessellate function method performs the actual tessellation.

Syntax

```
Result = Obj->[IDLgrTessellator::]Tessellate( Vertices, Poly [, AUXDATA=variable]  
[, /QUIET] )
```

Return Value

Returns 1, and the contents of Vertices and Poly are set to the results of the tessellation. Returns 0 if tessellation fails.

Arguments

If the tessellation succeeds, IDLgrTessellator::Tessellate returns 1 and the contents of Vertices and Poly are set to the results of the tessellation. If the tessellation fails, the function returns 0.

Vertices

A $2 \times n$ array if all the input polygons were 2-D. A $3 \times n$ array if all the input polygons were 3-D.

Poly

An array of polygon descriptions. A polygon description is an integer or long word array of the form: $[n, i_0, i_1, \dots, i_{n-1}]$, where n is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the X, Y, and Z arguments that represent the polygon vertices.

Note

On output, the *Vertices* array can be used as the value of the DATA property, and the *Poly* array can be used as the value of the POLYGON property, of an IDLgrPolygon object.

Keywords

AUXDATA

Set this keyword to a named variable that receives the auxiliary data associated with each vertex returned in the Vertices argument. The data is an $[m, n]$ array where m is the number of per-vertex auxiliary data items specified in the call(s) to the AddPolygon method, and n is the number of vertices returned in the Vertices argument. The type of the returned auxiliary data is the same as the type of the data supplied with the AUXDATA keyword in the last call to AddPolygon.

QUIET

Set this keyword to suppress warning and error message generation due to tessellation errors. !ERROR_STATE is not updated in the case of the return value being '0' when the QUIET keyword is specified.

Version History

5.0	Introduced
5.6	Added AUXDATA keyword

IDLgrText

A text object represents one or more text strings that share common rendering attributes. An IDLgrText object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Tip

The IDLgrTextEdit object class is a helper class that extends the IDLgrText object class, adding methods to delete text, insert text, and position the cursor. If you plan to implement any of these actions, consider using IDLgrTextEdit objects in preference to IDLgrText objects. See “[IDLgrTextEdit](#)” on page 4482 for details.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrText::Init](#)” on page 4479.

Properties

Objects of this class have the following properties. See “[IDLgrText Properties](#)” on page 4453 for details on individual properties.

- [ALIGNMENT](#)
- [ALPHA_CHANNEL](#)
- [CHAR_DIMENSIONS](#)
- [COLOR](#)
- [DEPTH_TEST_FUNCTION](#)
- [DRAW_CURSOR](#)
- [FILL_BACKGROUND](#)
- [FONT](#)
- [KERNING](#)
- [ALL](#)
- [BASELINE](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [ENABLE_FORMATTING](#)
- [FILL_COLOR](#)
- [HIDE](#)
- [LOCATIONS](#)

- [ONGLASS](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SELECTION_LENGTH](#)
- [SHADER](#)
- [UPDIR](#)
- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)
- [PALETTE](#)
- [RECOMPUTE_DIMENSIONS](#)
- [RENDER_METHOD](#)
- [SELECTION_START](#)
- [STRINGS](#)
- [VERTICAL_ALIGNMENT](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrText::Cleanup](#)
- [IDLgrText::GetCTM](#)
- [IDLgrText::GetIndexAtCoord](#)
- [IDLgrText::GetIndexRelativeTo](#)
- [IDLgrText::GetProperty](#)
- [IDLgrText::Init](#)
- [IDLgrText::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added CLIP_PLANES property

6.4	Added SHADER property
7.0.6	Added GetIndexAtCoord and GetIndexRelativeTo methods. Added SELECTION_START, SELECTION_LENGTH, DRAW_CURSOR properties.

Character Indices in Text Strings

The IDLgrText property [SELECTION_START](#) uses the *character index* to position the cursor or the edge of a selection in the string defined by the text object. The character index is a zero-based identifier of the position just to the left of the character identified. For example, in the following string of characters:

```
String of characters
```

the character index 7 specifies the position between the first space character and the letter “o” in the word “of.”

In many cases, the location within a visible string of characters that corresponds to a particular character index value is obvious. However, when the text string specified to the IDLgrText object contains *embedded formatting commands* to change the size, position, or font face, the character indices no longer correspond directly to the locations of the characters displayed on the screen.

The following example shows regular text as well as superscript and subscript.

Text^{Super}_{Sub}

To create this example in an IDLgrText object, you would set the [STRINGS](#) property to the following value, which includes embedded formatting commands to create the superscript and subscript characters:

```
Text!USuper!DSub
```

Note

You must also set the [ENABLE_FORMATTING](#) property of the IDLgrText object for embedded formatting codes to be honored.

The embedded formatting commands themselves are not displayed. In this example, any text following (!U) displays as supertext, while text following (!D) displays as subtext. See these characters in the grayed-out areas in the next example. This example shows the character index used when specifying a value via the [SELECTION_START](#) property.

The index specifies a location within the string. Placing the insertion cursor at an index number means that the cursor displays just before the character. In the

following example, you would use index number 16 to place the insertion cursor after the last character.

Some indices do not make sense to use and are ignored. For example, index number 12 would place the cursor in between two format control characters.

T	e	x	t	!	U	S	u	p	e	r	!	D	S	u	b
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Note

For more information on formatting text annotations, see “[Embedded Formatting Commands](#)” in Appendix H.

Examples

The following examples illustrate the IDLgrText properties SELECTION_START and SELECTION_LENGTH. The text selection between the bars equates to the following property values (if defined from left to right):

```
SELECTION_START=1
```

```
SELECTION_LENGTH=7
```

Because the direction of these properties can start from left to right or right to left, the same selection can also be defined from right to left as:

```
SELECTION_START=8
```

```
SELECTION_LENGTH=-7
```

T	e	x	t	!	U	S	u	p	e	r	!	D	S	u	b
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

A selection start between two characters like the one shown below is defined as:

```
SELECTION_START=10
```

SELECTION_LENGTH=0

T	e	x	t	!	U	S	u	p	e	r	!	D	S	u	b
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

IDLgrText Properties

IDLgrText objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrText::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrText::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrText::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties:

- [ALIGNMENT](#)
- [ALPHA_CHANNEL](#)
- [CHAR_DIMENSIONS](#)
- [COLOR](#)
- [DEPTH_TEST_FUNCTION](#)
- [DRAW_CURSOR](#)
- [FILL_BACKGROUND](#)
- [FONT](#)
- [KERNING](#)
- [ONGLASS](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [SELECTION_LENGTH](#)
- [SHADER](#)
- [UPDIR](#)
- [XCOORD_CONV](#)
- [YCOORD_CONV](#)
- [ZCOORD_CONV](#)
- [ALL](#)
- [BASELINE](#)
- [CLIP_PLANES](#)
- [DEPTH_TEST_DISABLE](#)
- [DEPTH_WRITE_DISABLE](#)
- [ENABLE_FORMATTING](#)
- [FILL_COLOR](#)
- [HIDE](#)
- [LOCATIONS](#)
- [PALETTE](#)
- [RECOMPUTE_DIMENSIONS](#)
- [RENDER_METHOD](#)
- [SELECTION_START](#)
- [STRINGS](#)
- [VERTICAL_ALIGNMENT](#)
- [XRANGE](#)
- [YRANGE](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent Properties](#)

ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested horizontal alignment of the text baseline. An alignment of 0.0 (the default) left-justifies the text at the given position; an alignment of 1.0 right-justifies the text, and an alignment of 0.5 centers the text over the given position.

Property Type	FLOAT		
Name String	Horizontal alignment		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

A floating-point value that determines the opacity of the text with respect to the background. Set this property to a value in the range [0.0, 1.0] (1.0 is the default) to draw the text foreground and background with the specified blending factor. A value of 1.0 draws the text opaquely without blending the text with objects already drawn on the destination. Edges of the glyphs are always blended. A value of 0.0 draws no text at all. A value in the middle of the range draws the text semi-transparently, which provides a way of creating labels that are visible while allowing features blocked by the labels to still be seen. This property is used only when the `RENDER_METHOD` in effect is 0 (Texture).

Note

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BASELINE

A two- or three-element floating-point vector describing the direction in which the baseline is to be oriented. Use this property in conjunction with the UPDIR property to specify the plane on which the text lies. The default BASELINE is [1.0,0,0] (i.e., parallel to the x-axis).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Baseline direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CHAR_DIMENSIONS

A two-element floating-point vector [*width*, *height*] indicating the dimensions (measured in data units) of a bounding box for each character, to be used when scaling text projected in three dimensions. If either *width* or *height* is zero, the text will be scaled such that if it were positioned halfway between the near and far clipping planes, it will appear at the point size associated with this text object’s font. The default value is [0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Note

If you set the CHAR_DIMENSIONS property to [0,0] (using the SetProperty method), indicating that IDL should calculate the text size, the value (returned by the GetProperty method) will not be updated to reflect the calculated size until you call either the Draw method or the GetTextDimensions method.

For example, if the VIEWPLANE_RECT of the view the text object is being rendered in is set equal to [0,0,10,10] (that is, it spans ten data units in each of the X and Y directions), setting the CHAR_DIMENSIONS property equal to [2, 3] will scale the text such that each character fills 20% of the X range and 30% of the Y range.

This property has no effect if the ONGLASS property is set equal to one.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COLOR

The color to be used as the foreground color for the text. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself “on top” of other objects already on the screen, even if the object is located behind them.

Note

Disabling depth testing also disables depth buffer writing. When disabling depth testing, the `DEPTH_TEST_FUNCTION` and `DEPTH_WRITE_DISABLE` properties are effectively ignored.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

Note

If depth testing (see `DEPTH_TEST_DISABLE` property) is disabled, depth writing is also automatically disabled.

This property is registered as an enumerated list, but it is hidden by default.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DRAW_CURSOR

A boolean value that indicates whether the insertion cursor is drawn when no text is selected. This has no effect on the display of selected text. It only determines whether the cursor is displayed. The default is 0.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: No	Registered: No

Possible uses for the `DRAW_CURSOR` property include:

- Hiding the cursor when a text box is not being edited
- Toggling the insertion cursor to blink as in some text editors

Example

In the following text example, the cursor is shown between two letters.

```
SELECTION_START=3 and DRAW_CURSOR=1.
```

Text^{Super}
Sub

Note

For information on how text elements are indexed, see [Character Indices in Text Strings](#).

ENABLE_FORMATTING

A Boolean value that determines whether the text object should honor embedded Hershey-style formatting codes within the strings. (Formatting codes are described in [Appendix H, “Fonts”](#).) The default is not to honor the formatting codes.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILL_BACKGROUND

Set this property to zero (the default) to render the text with a transparent bitmap background, allowing graphics behind the text to show through between the glyphs. Set this property to non-zero to draw the text bitmap background with the color specified by the FILL_COLOR property. This property can only be used when RENDER_METHOD is set to 0 (Texture).

Property Type	Boolean		
Name String	Fill background		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FILL_COLOR

An integer vector that determines whether to use a text background color other than the view color. Set this property to -1 (the default) to specify that the text background should be drawn using the view color. Set this property to a three-element vector [*red*, *green*, *blue*] or color index value to specify that the text bitmap background should be

drawn using the specified color. This property is used only when the `FILL_BACKGROUND` property has a non-zero value and the `RENDER_METHOD` in effect is 0 (Texture).

In a property sheet, this property appears as a color property

Property Type	COLOR		
Name String	Fill background		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

FONT

An object reference to an instance of an `IDLgrFont` object class to describe the font to use to draw this string. The default is 12 point Helvetica. See [IDLgrFont](#) for details.

Note

If the default font is in use, retrieving the value of the `FONT` property (using the `GetProperty` method) will return a null object.

Note

Objects specified via this property are not automatically cleaned up when the `IDLgrText` object is destroyed.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HIDE

A Boolean value or an enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

KERNING

A Boolean value that determines whether to enable kerning while rendering characters. Kerning reduces the amount of space between glyphs if the shape of each glyph allows it, according to the font information stored in the font's file (e.g., AV). Set this property to a non-zero value (the default is zero) to enable kerning. Enabling kerning may not necessarily result in rendering glyphs more closely together because some fonts do not contain the required kerning information. This property is used only when the `RENDER_METHOD` in effect is 0 (Texture).

Property Type	Boolean		
Name String	Kerning		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATIONS

A floating-point array of one or more two- or three-element vectors specifying the coordinates (measured in data units) used to position the string(s). The default location for each string is [0,0,0]. Each vector is of the form [x, y] or [x, y, z]; if z is not provided, it is assumed to be zero. Each location corresponds to a string in the *String* argument; the number of locations should be equal the number of strings. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Text locations		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ONGLASS

A Boolean value that indicates whether the text should be displayed “on the glass”. Text that is drawn “on the glass” always faces the viewer, regardless of the 3-D orientation of the objects “underneath” the glass. The default is projected 3-D text.

Property Type	Boolean		
Name String	On glass		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

Note

Objects specified via this property are not automatically cleaned up when the IDLgrText object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RECOMPUTE_DIMENSIONS

An integer value that indicates when this text object's character dimensions (refer to the CHAR_DIMENSIONS property) are to be recomputed automatically:

0	The physical size of the text is affected by model and view transforms. The size of the text in terms of data units is obtained from CHAR_DIMENSIONS. Since the character dimensions are specified in data units, the text will maintain the data space size specified by CHAR_DIMENSIONS as the transforms change. In other words, the physical text size changes along with other primitives. If the value of this property is [0, 0], the text font's point size is used to compute the physical size of the text in terms of data units using the transforms in effect for the first draw. This setting is the default value for this property.
1	The physical size of the text is only affected by model transforms. The CHAR_DIMENSIONS property is ignored. The size of the text is computed from the font's point size the first time it is drawn, and IDL does not try to keep the size of the text constant with respect to changes in the model transforms.
2	The physical size of the text is held constant, even as the model and view change. The CHAR_DIMENSIONS property is ignored and the text is always drawn with a physical size equal to the text font's point size. IDL adjusts its internal text transforms to maintain the physical size of the text.

Property Type	ENUMLIST		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as

“Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_METHOD

A Boolean value or enumerated list item that determines how the text object will be rendered. Set this property to one of the following values:

Value	Property Sheet Value	Description
0	Texture	IDL renders the text by placing a bitmap representation of a glyph into a texture map and then rendering a polygon with the texture map. The <code>FILL_BACKGROUND</code> , <code>ALPHA_CHANNEL</code> , and <code>FILL_COLOR</code> properties control the drawing of the background portions of the texture map and how the entire texture map is blended into the scene. Leaving these three properties set to their default values produces a result that closely approximates the <code>TRIANGLES</code> rendering method. One important difference is that the glyph bitmaps are generated by the FreeType font rendering library, producing glyphs that are more accurately rendered and anti-aliased than those drawn with the <code>TRIANGLES</code> method. The <code>TEXTURE</code> method cannot be used on indexed color destinations. The text is rendered with the <code>TRIANGLES</code> method if the destination color model is indexed.
1	Triangles	IDL renders the text by tessellating the glyph outline into a set of small triangles that are then drawn to produce the solid glyph. IDL also draws a blended line around the edge of the glyph to approximate anti-aliasing. This setting forces IDL to use the process it used as the default before IDL 6.0.

Property Type	ENUMLIST		
Name String	Render method		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SELECTION_LENGTH

An integer value that specifies the length of the selection, starting from the cursor. Zero indicates no text is selected; the insertion cursor is just placed at SELECTION_START. The selection length may be positive or negative. A positive number means that the selection begins on the left and moves to the right. A negative number means that the selection begins on the right and moves to the left. The default behavior is zero; no selection.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: No	Registered: No

Note

See “[Character Indices in Text Strings](#)” on page 4450 for examples.

SELECTION_START

An integer value that specifies the character index at which text selection starts, which is the same as the position of the insertion cursor. This index is the space immediately before the character with the given index in the string. The default value is zero; the beginning.

See “[Character Indices in Text Strings](#)” on page 4450 for more information.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: No	Registered: No

STRINGS

The string (or vector of strings) associated with the text object.

Specifying this property is the same as specifying the optional *String* argument to the [IDLgrText::Init](#) method.

If the number of strings matches the number of locations (as specified by the LOCATIONS property), the existing locations are used.

Note

If the number of strings *does not* match the number of locations, the number of locations is modified to match the number of strings, and the location value for each string is reset to [0,0,0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Text strings		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the text is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional text objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UPDIR

A two- (or three-) element floating-point vector describing the vertical direction for the string. The *upward direction* is the direction defined by a vector pointing from the origin to the point specified. Use this property in conjunction with the BASELINE property to specify the plane on which the text lies; the direction specified by UPDIR should be orthogonal to the direction specified by BASELINE. The default UPDIR is [0.0, 1.0, 0.0] (i.e., parallel to the *Y* axis).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Up direction		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VERTICAL_ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested vertical alignment of the text. An alignment of 0.0 (the default) bottom-justifies the text at the given location; an alignment of 1.0 top-justifies the text at the given location.

Property Type	FLOAT		
Name String	Vertical alignment		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element floating-point vector of the form $[x_{min}, x_{max}]$ that specifies the range of x data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element floating-point vector of the form $[y_{min}, y_{max}]$ that specifies the range of y data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZRANGE

A two-element floating-point vector of the form $[zmin, zmax]$ that specifies the range of z data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

Note

Until the text is drawn to the destination object, the [XYZ]RANGE properties will only report the locations of the text. Use the `GetTextDimensions` method of the destination object to get the data dimensions of the text prior to a draw operation.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrText::Cleanup

The IDLgrText::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrText::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrText::GetCTM

The IDLgrText::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrText::]GetCTM( [, DESTINATION=objref] [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the text object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrText::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the `GetCTM` method is called up to but not including the specified model object.

Version History

7.06	Introduced
------	------------

IDLgrText::GetIndexAtCoord

The IDLgrText::GetIndexAtCoord function method returns the index of the character in the string closest to a specified screen coordinate.

Tip

In the context of this method, screen coordinates are normalized coordinates defined by the bounding box of the text object.

Syntax

Result = *Obj*->[IDLgrText::]GetIndexAtCoord(*Window*, *X*, *Y*)

Return Value

An integer specifying the character index of the character closest to the position specified by *X* and *Y*.

Arguments

Window

An object reference to the IDLgrWindow object in which the text appears.

X

A floating-point value between 0.0 and 1.0 specifying the horizontal coordinates relative to the bounding box of the text object.

Y

A floating-point value between 0.0 and 1.0 specifying the vertical coordinates relative to the bounding box of the text object.

Keywords

None

Example

The bounding box of the IDLgrText object is defined as shown below. The coordinates are the same regardless of the size of the text box. So the following call:

```
index=Obj->GetIndexAtCoord(oWin, 0.22, 0.77)
```

returns 2, which is the index of the closest insertion point.

See [“Character Indices in Text Strings”](#) on page 4450 for more information.

Version History

7.0.6	Introduced
-------	------------

IDLgrText::GetIndexRelativeTo

The IDLgrText::GetIndexRelativeTo function method returns the index of the character in the string closest to a given coordinate. See “[Character Indices in Text Strings](#)” on page 4450 for more information.

Syntax

Result = *Obj*->[IDLgrText:]GetIndexRelativeTo(*Window*, *Index*, *Direction*)

Return Value

An integer specifying the character index of the closest character above, below, or to either side of the index specified by *Index*.

Arguments

Window

An object reference to the IDLgrWindow object in which the text appears.

Index

An integer specifying the character index of the character from which the search should begin.

Direction

An integer specifying the direction from *Index*. Possible values are:

- 0 — left
- 1 — right
- 2 — up
- 3 — down

Keywords

None.

Example

So the following call:

```
index=Obj->GetIndexRelativeTo(oWin, 11, 2)
```

returns 3, the closest insertion point above 11.

The following call:

```
index=Obj->GetIndexRelativeTo(oWin, 13, 3)
```

returns 19, the closest insertion point below 11.

Version History

7.0.6	Introduced
-------	------------

IDLgrText::GetProperty

The IDLgrText::GetProperty procedure method retrieves the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrText::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrText Properties](#)” on page 4453 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrText::Init

The IDLgrText::Init function method initializes the text object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrText' [, *String or vector of strings*] [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrText::]Init([*String or vector of strings*] [, *PROPERTY=value*])
(*In a lifecycle method only.*)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

Note

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

Note

The value specified by the *String* argument is used to initialize the value of the **STRINGS** property of the IDLgrText object.

Keywords

Any property listed under “[IDLgrText Properties](#)” on page 4453 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrText:: SetProperty

The IDLgrText::SetProperty procedure method sets the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrText::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “IDLgrText Properties” on page 4453 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrTextEdit

A text editing object is an extension of the [IDLgrText](#) object class that provides several methods that allow modification of the existing text strings. The IDLgrTextEdit object class exposes all of the properties and methods of the IDLgrText superclass.

Consider using an IDLgrTextEdit object if your application will allow interactive editing of text objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrtextedit__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

[IDLgrText](#)

Creation

See “[IDLgrTextEdit::Init](#)” on page 4489.

Properties

Objects of this class have no properties of their own, but do have properties inherited from the [IDLgrText](#) class. See “[IDLgrText Properties](#)” on page 4453.

Methods

This class has the following methods:

- [IDLgrTextEdit::Cleanup](#)
- [IDLgrTextEdit::Delete](#)
- [IDLgrTextEdit::GetProperty](#)
- [IDLgrTextEdit::Init](#)
- [IDLgrTextEdit::Insert](#)
- [IDLgrTextEdit::MoveCursor](#)
- [IDLgrTextEdit::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit Properties

IDLgrTextEdit objects classes have no properties of their own, but do have properties inherited from the [IDLgrText](#) class. See “[IDLgrText Properties](#)” on page 4453.

IDLgrTextEdit::Cleanup

The IDLgrTextEdit::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrTextEdit::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit::Delete

The IDLgrTextEdit::Delete procedure removes text from a string at the current cursor position. If text is selected, the selection is deleted and the selection length is reset to zero.

If no text is selected, a single character is deleted to the left of the cursor unless the AFTER keyword is used.

Syntax

```
Obj->[IDLgrTextEdit::]DELETE [, /AFTER] [, TEXT=variable]
```

Arguments

None.

Keywords

AFTER

Set this keyword to delete the character *after* (to the right of) the cursor (as the Delete key does). By default, the Delete method deletes the character *before* (to the left of) the cursor (as the Backspace key does).

TEXT

Set this keyword equal to a named variable that will contain the characters that were removed from the string.

Example

The following example illustrates several IDLgrTextEdit procedures, including DELETE. Copy and paste the following sections to the IDL command line or click on them from the online help to run them in IDL.

```
; Create a window, view, and model
oWindow = OBJ_NEW('IDLgrWindow', RETAIN=2)
oView = Obj_new('idlgview')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel

; Create the initial line of text and text location
oText = obj_new('idlgtextedit', 'That text was difficult', $
```

```

        FONT=oFont, LOCATIONS=[-0.8,0])
oModel->Add, oText

; Select the location to draw the cursor
oText->SetProperty, SELECTION_START=8, /DRAW_CURSOR

; Draw the window
oWindow->Draw, oView

```

The view should look like this:

That text| was difficult

The next part deletes the “x” and inserts an “s” in its place:

```

; Delete the character to the left of the cursor
oText->Delete, TEXT=DeleteChar
; Insert an 's' to change the word to 'test'
oText->Insert, 's'
oWindow->Draw, oView

```

The following code moves the cursor to the correct position to add more text:

```

; Move the cursor one character to the end of the word
oText->MoveCursor, oWindow, DIRECTION=1

; Add more text
oText->Insert, ' in class'
oWindow->Draw, oView

```

The view should now look like the following:

That test in class| was difficult

Finally, destroy the IDLgrWindow, and IDLgrView objects before we proceed:

```
OBJ_DESTROY, [oWindow, oView, oFont]
```

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit::GetProperty

The IDLgrTextEdit::GetProperty procedure method retrieves the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrTextEdit::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

The IDLgrTextEdit object class does not have properties of its own, but does inherit all of the properties of its superclasses. Any property listed under “[IDLgrText Properties](#)” on page 4453 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit::Init

The IDLgrTextEdit::Init function method initializes the text editing object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrTextEdit' [, String or vector of strings]  
          [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrTextEdit::]Init([String or vector of strings]  
          [, PROPERTY=value])    (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

Note

The value specified by the *String* argument is used to initialize the value of the **STRINGS** property of the underlying IDLgrText object.

Note

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

Keywords

The IDLgrTextEdit object class does not have properties of its own, but does inherit all of the properties of its superclasses. Any property listed under “[IDLgrText Properties](#)” on page 4453 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit::Insert

The IDLgrTextEdit::Insert procedure method inserts text at the current cursor position. If text is selected, it overwrites the selected text and sets the selection length to zero. (See the [SELECTION_LENGTH](#) property of the [IDLgrText](#) object for more information.)

Syntax

Obj->[IDLgrTextEdit::]Insert, *Text*

Arguments

Text

A string containing the text to be inserted.

Keywords

None

Examples

Example 1

```
oWindow = OBJ_NEW('IDLgrWindow', RETAIN=2)
oView = Obj_new('idlgrview')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
oText = obj_new('idlgrtextedit', 'This is a string', $
    FONT=oFont, LOCATIONS=[-0.9,0])
oModel->Add, oText
oWindow->Draw, oView
oText->SetProperty, SELECTION_START=10, /DRAW_CURSOR
oWindow->Draw, oView
```

This is a |string

To add another string at this position, use:

```
oText->Insert, 'longer '
oWindow->Draw, oView
```

Which results in the following string:

This is a longer | string

Destroy the IDLgrWindow and IDLgrView objects before we proceed:

```
OBJ_DESTROY, [oWindow, oView, oFont]
```

Example 2

The next example shows selected text in a string that will be replaced using INSERT:

```
oWindow = OBJ_NEW('IDLgrWindow')
oView = Obj_new('idlgrview')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
oText = obj_new('idlgtextedit', 'A cute dog', $
    FONT=oFont, LOCATIONS=[-0.9,0])
oModel->Add, oText
oText->SetProperty, SELECTION_START=2, SELECTION_LENGTH=4, $
    /DRAW_CURSOR
oWindow->Draw, oView
```

A **cute** | dog

To replace the selected string with the word “brown,” use:

```
oText->Insert, 'brown'
oWindow->Draw, oView
```

Which results in the following string:

A brown | dog

Destroy the IDLgrWindow and IDLgrView objects.

```
OBJ_DESTROY, [oWindow, oView, oFont]
```

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit::MoveCursor

The IDLgrTextEdit::MoveCursor procedure method moves the cursor one space in the direction indicated by the direction argument. See [“Character Indices in Text Strings”](#) on page 4450 for more information.

Syntax

```
Obj->[IDLgrTextEdit::]MoveCursor, Window [, DIRECTION={0 | 1 | 2 | 3}]  
[, /SELECT]
```

Arguments

Window

An object reference to the IDLgrWindow object in which the text appears.

Keywords

DIRECTION

Set this keyword to specify the direction the cursor moves. Possible values are:

- 0 — left (the default)
- 1 — right
- 2 — up
- 3 — down

SELECT

If set, this keyword moves the cursor and selects the text in the given direction. Otherwise, it moves the cursor and sets the selection length to zero. (See the [SELECTION_LENGTH](#) property of the IDLgrText object for more information.)

Example

See [“IDLgrTextEdit::Delete”](#) on page 4486.

Version History

7.0.6	Introduced
-------	------------

IDLgrTextEdit:: SetProperty

The IDLgrTextEdit::SetProperty procedure method sets the value of a property or group of properties for the text.

Syntax

Obj->[IDLgrTextEdit::]SetProperty[, *PROPERTY=*value]

Arguments

None

Keywords

The IDLgrTextEdit object class does not have properties of its own, but does inherit all of the properties of its superclasses. Any property listed under “IDLgrText Properties” on page 4453 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Example

See “IDLgrTextEdit::Delete” on page 4486 and “IDLgrTextEdit::Insert” on page 4491.

Version History

7.0.6	Introduced
-------	------------

IDLgrView

A view object represents a rectangular area in which graphics objects are drawn. It is a container for objects of the [IDLgrModel](#) class.

Note

See [Chapter 3, “Positioning Objects in a View”](#) (*Object Programming*) for more information on using the properties and methods of the view object.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrView::Init](#)” on page 4513.

Properties

Objects of this class have the following properties. See “[IDLgrView Properties](#)” on page 4499 for details on individual properties.

- [ALL](#)
- [COLOR](#)
- [DEPTH_CUE](#)
- [DIMENSIONS](#)
- [DOUBLE](#)
- [EYE](#)
- [HIDE](#)
- [LOCATION](#)
- [PARENT](#)
- [PROJECTION](#)
- [REGISTER_PROPERTIES](#)
- [TRANSPARENT](#)

- [UNITS](#)
- [VIEWPLANE_RECT](#)
- [ZCLIP](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrView::Add](#)
- [IDLgrView::Cleanup](#)
- [IDLgrView::GetByName](#)
- [IDLgrView::GetProperty](#)
- [IDLgrView::Init](#)
- [IDLgrView::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
-----	------------

IDLgrView Properties

IDLgrView objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrView::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrView::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrView::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [COLOR](#)
- [DEPTH_CUE](#)
- [DIMENSIONS](#)
- [DOUBLE](#)
- [EYE](#)
- [HIDE](#)
- [LOCATION](#)
- [PARENT](#)
- [PROJECTION](#)
- [REGISTER_PROPERTIES](#)
- [TRANSPARENT](#)
- [UNITS](#)
- [VIEWPLANE_RECT](#)
- [ZCLIP](#)

In addition, objects of this class inherit:

- [IDL_Container](#)
- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR

The color for the view. This is the color to which the view area will be erased before its contents are drawn. The color may be specified as a color lookup table index or as a three-element vector [*red*, *green*, *blue*]. The default is [255, 255, 255] (white).

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DEPTH_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color. Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Depth cue		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the viewport (the rectangle in which models are displayed on a graphics destination). By default, the viewport dimensions are set to [0, 0], which indicates that it will match the dimensions of the graphics destination to which it is drawn. The dimensions are measured in the units specified by the UNITS property.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

See “[Location](#)” (Chapter 3, *Object Programming*) for more information.

DOUBLE

A Boolean value that controls the precision used for rendering the entire contents of the view. If set, IDL calculates the transformations used for the modeling and view transforms using double-precision floating-point arithmetic. This allows the values specified for the VIEWPLANE_RECT, modeling transforms in IDLgrModel objects, and coordinate data in atomic graphic objects to be used as double-precision before mapping to device coordinates.

Note

If this property is set to 0, IDL uses single-precision floating-point arithmetic for these values, which can cause loss of significance and incorrect rendering of data. Setting this property to 1 may impact graphics performance and should only be used when handling data requiring double precision.

The default value is 0.

Property Type	Boolean		
Name String	Double precision		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

EYE

A floating-point value that specifies the distance from the eyepoint to the viewplane ($Z=0$). The default is 4.0. The eyepoint is always centered within the viewplane rectangle. (That is, if the `VIEWPLANE_RECT` property is set equal to `[0,0,1,1]`, the eyepoint will be at $X=0.5, Y=0.5$.) IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	FLOAT		
Name String	Eye distance		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

Note

See [“Eye Position”](#) (Chapter 3, *Object Programming*) for details.

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LOCATION

A two-element floating-point vector of the form $[x, y]$ specifying the position of the lower left corner of the view. The default is $[0, 0]$, and is measured in units specified by the UNITS property

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Viewport location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

Note

See “[Location](#)” (Chapter 3, *Object Programming*) for more information.

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PROJECTION

An integer value or enumerated list item indicating the type of projection to use within this view. All models displayed within this view will be projected using this type of projection. Valid values are:

Value	Property Sheet Value	Description
0	None	Same result as setting Orthogonal or 1
1	Orthogonal	Models are projected along lines perpendicular to the view plane (the default)
2	Perspective	Models are projected toward the eye (located at the origin), which is the apex of the viewing frustum. With a perspective projection, models that are farther away from the eye will appear smaller in the view than models that are nearer to the eye.

Property Type	ENUMLIST		
Name String	Projection		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

Note

See [“Projection”](#) (Chapter 3, *Object Programming*) for details.

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TRANSPARENT

A Boolean value that determines whether to disable the viewport erase, making the viewport transparent. If this value is false, the viewport is erased and the depth buffer initialized. If this value is true, the viewport is not erased and the depth buffer is not initialized.

Property Type	Boolean		
Name String	Transparent		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

UNITS

An integer value or enumerated list item that specifies the units of measure for this view:

Value	Property Sheet Value	Description
0	Device	Device units are unit of measure (the default)
1	Inches	Inches are unit of measure
2	Centimeters	Centimeters are unit of measure
3	Normalization	Normalized units (relative to the graphics destination's <i>rect</i>) are unit of measure

Note

If you set the UNITS property (using the SetProperty method) of a view without also setting the LOCATION and DIMENSIONS properties, IDL will use the existing size and location values in the new units, *without conversion*. This means that if your view's location and dimensions were previously measured in centimeters, and you change the value of UNITS to 1 (measurement in inches), the actual size of the view object will change.

Property Type	ENUMLIST		
Name String	Units		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VIEWPLANE_RECT

A four-element floating-point vector of the form $[x, y, width, height]$ to describe the bounds in x and y of the view volume. Objects within the view volume are projected into the viewport. These values are measured in normalized space. The default is $[-1.0, -1.0, 2.0, 2.0]$ IDL converts, maintains, and returns this data as double-precision floating-point.

Note

The z bounds of the view volume are set via the ZCLIP property. The viewplane rectangle is always located at $Z=0$.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Viewplane rectangle		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

Note

See “[View Volume](#)” (Chapter 3, *Object Programming*) for details.

ZCLIP

A two element floating-point vector representing the near and far clipping planes to be applied to the objects in this view. The vector should take the form $[near, far]$. By default, these values are $[1, -1]$. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Z clipping		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

IDLgrView::Add

The IDLgrView::Add procedure method adds a child to this view.

Syntax

Obj->[IDLgrView::]Add, *Model* [, POSITION=*index*]

Arguments

Model

An instance of the IDLgrModel object class.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.0	Introduced
-----	------------

IDLgrView::Cleanup

The IDLgrView::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrView::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrView::GetByName

The `IDLgrView::GetByName` function method finds contained objects by name. If the named object is not found, the `GetByName` function returns a null object reference.

Note

The `GetByName` function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrView::]GetByName(*Name*)

Return Value

Returns contained objects by name. If the named object is not found, the `GetByName` function returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of `object3` would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the `GetByName` method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrView::GetProperty

The IDLgrView::GetProperty procedure method retrieves the value of the property or group of properties for the view.

Syntax

Obj->[IDLgrView::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4499 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrView::Init

The IDLgrView::Init function method initializes the view object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLgrView' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLgrView::]Init( [, PROPERTY=value]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrView Properties](#)” on page 4499 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.0	Introduced
-----	------------

IDLgrView:: SetProperty

The IDLgrView::SetProperty procedure method sets the value of the property or group of properties for the view.

Syntax

Obj->[IDLgrView::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrView Properties” on page 4499 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrViewgroup

The IDLgrViewgroup object is a simple container object, very similar to the IDLgrScene object. It contains one or more IDLgrView objects and an IDLgrScene can contain one or more of these objects. This object is special in that it can also contain objects which do not have a Draw method (e.g. IDLgrPattern and IDLgrFont). An IDLgrViewgroup object cannot be returned by a call to the IDLgrWindow::Select method or the IDLgrBuffer::Select method.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Creation

See “[IDLgrViewgroup::Init](#)” on page 4525.

Properties

Objects of this class have the following properties. See “[IDLgrViewgroup Properties](#)” on page 4518 for details on individual properties.

- [ALL](#)
- [HIDE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrViewgroup::Add](#)
- [IDLgrViewgroup::Cleanup](#)
- [IDLgrViewgroup::GetByName](#)
- [IDLgrViewgroup::GetProperty](#)

- [IDLgrViewgroup::Init](#)
- [IDLgrViewgroup::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.1	Introduced
-----	------------

IDLgrViewgroup Properties

IDLgrViewgroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrViewgroup::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrViewgroup::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrViewgroup::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [HIDE](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)

In addition, objects of this class inherit:

- [IDL_Container](#)
- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

HIDE

A Boolean value or enumerated list item that indicates whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PARENT

An object reference to the object that contains this viewgroup.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrViewgroup::Add

The IDLgrViewgroup::Add function method verifies that the added item is not an instance of the IDLgrScene or IDLgrViewgroup object. If it is not, IDLgrViewgroup:Add adds the object to the specified viewgroup.

Syntax

Obj->[IDLgrViewgroup::]Add, *Object* [, POSITION=*index*]

Arguments

Object

An instance of an object or a list of objects. Objects which subclass IDLgrScene or IDLgrViewgroup can not be added (avoiding circularity constraints). All other objects are allowed.

Keywords

POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

Version History

5.1	Introduced
-----	------------

IDLgrViewgroup::Cleanup

The IDLgrViewgroup::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrViewgroup::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrViewgroup::GetByName

The IDLgrViewgroup::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Note

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

Syntax

Result = *Obj*->[IDLgrViewgroup::]GetByName(*Name*)

Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

Arguments

Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if *object1* contains *object2*, which in turn contains *object3*, the string specifying the fully qualified object name of *object3* would be '*object1/object2/object3*'.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the / character represents the top of an object hierarchy. The string '*..*' represents the object one level “up” in the hierarchy.

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrViewgroup::GetProperty

The IDLgrViewgroup::GetProperty procedure method retrieves the value of a property or group of properties for the viewgroup object.

Syntax

Obj->[IDLgrViewgroup::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLgrViewgroup Properties](#)” on page 4518 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrViewgroup::Init

The IDLgrViewgroup::Init function method initializes the viewgroup object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrViewgroup' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrViewgroup::]Init([, *PROPERTY=value*]) (In a lifecycle method only.)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrViewgroup Properties” on page 4518 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrViewgroup:: SetProperty

The IDLgrViewgroup::SetProperty procedure method sets the value of a property or group of properties for the viewgroup.

Syntax

Obj->[IDLgrViewgroup::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLgrViewgroup Properties” on page 4518 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrVolume

A volume object represents a mapping from a three-dimensional array of data to a three-dimensional array of voxel colors, which, when drawn, are projected to two dimensions.

An IDLgrVolume object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrVolume::Init](#)” on page 4554.

Properties

Objects of this class have the following properties. See “[IDLgrVolume Properties](#)” on page 4530 for details on individual properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOUNDS](#)
- [CLIP_PLANES](#)
- [COMPOSITE_FUNCTION](#)
- [DATA0](#)
- [DATA1](#)
- [DATA2](#)
- [DATA3](#)
- [DEPTH_CUE](#)
- [HIDE](#)
- [HINTS](#)
- [INTERPOLATE](#)
- [LIGHTING_MODEL](#)
- [OPACITY_TABLE0](#)
- [OPACITY_TABLE1](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RENDER_STEP](#)
- [RGB_TABLE0](#)
- [RGB_TABLE1](#)
- [SHADER](#)
- [TWO_SIDED](#)

- `VALID_DATA`
- `XCOORD_CONV`
- `YCOORD_CONV`
- `ZBUFFER`
- `ZERO_OPACITY_SKIP`
- `VOLUME_SELECT`
- `XRANGE`
- `YRANGE`
- `ZCOORD_CONV`
- `ZRANGE`

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- `IDLgrVolume::Cleanup`
- `IDLgrVolume::ComputeBounds`
- `IDLgrVolume::GetCTM`
- `IDLgrVolume::GetProperty`
- `IDLgrVolume::Init`
- `IDLgrVolume::PickVoxel`
- `IDLgrVolume::SetProperty`

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
5.6	Added <code>CLIP_PLANES</code> keyword
6.0	Deprecated <code>CUTTING_PLANES</code> property
6.1	Added <code>ALPHA_CHANNEL</code> property
6.2	Removed <code>NO_COPY</code> property and documented as a keyword on <code>IDLgrVolume::Init</code> and <code>IDLgrVolume::SetProperty</code>
6.4	Added <code>SHADER</code> property

For more information on deprecated features, see [Appendix I, “IDL API History”](#).

IDLgrVolume Properties

IDLgrVolume objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrVolume::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrVolume::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrVolume::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [ALPHA_CHANNEL](#)
- [AMBIENT](#)
- [BOUNDS](#)
- [CLIP_PLANES](#)
- [COMPOSITE_FUNCTION](#)
- [DATA0](#)
- [DATA1](#)
- [DATA2](#)
- [DATA3](#)
- [DEPTH_CUE](#)
- [HIDE](#)
- [HINTS](#)
- [INTERPOLATE](#)
- [LIGHTING_MODEL](#)
- [OPACITY_TABLE0](#)
- [OPACITY_TABLE1](#)
- [PARENT](#)
- [REGISTER_PROPERTIES](#)
- [RENDER_STEP](#)
- [RGB_TABLE0](#)
- [RGB_TABLE1](#)
- [SHADER](#)
- [TWO_SIDED](#)
- [VALID_DATA](#)
- [VOLUME_SELECT](#)
- [XCOORD_CONV](#)
- [XRANGE](#)
- [YCOORD_CONV](#)
- [YRANGE](#)
- [ZBUFFER](#)
- [ZCOORD_CONV](#)
- [ZERO_OPACITY_SKIP](#)
- [ZRANGE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Note

This structure returns COLOR, DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, and DEPTH_WRITE_DISABLE properties that are consistent with other graphic objects. However, these properties are not used by the IDLgrVolume object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ALPHA_CHANNEL

Apply to the volume only when the volume is rendered with a destination rendering quality setting of Low (0). In the case, the volume is rendered as a wireframe cube. Set this property to a floating-point value in the range [0.0, 1.0] to specify the opacity of the wireframe cube. The default value of 1.0 causes IDL to draw the wireframe cube completely opaque. If the value of this property is less than 1.0, then the pixels of the wireframe cube are blended with the pixels already on the screen, where the color of the wireframe cube is multiplied by the alpha value and the pixels already on the screen are multiplied by 1.0-alpha.

Because an object can only be blended with objects already drawn on the screen, the drawing order of the objects must be considered carefully in order to obtain the desired results.

This property has no effect on devices using indexed color mode.

Note

For more detailed information on alpha channel support for IDL Object Graphics, see “[Controlling Object Transparency](#)” (Chapter 2, *Object Programming*).

Property Type	Float-point value		
Name String	<i>Transparency</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

AMBIENT

The color and intensity of the volume’s base ambient lighting. Color is specified as a three-element vector [*red, green, blue*]. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING_MODEL is set.

In a property sheet, this property appears as a color property.

Property Type	COLOR		
Name String	Ambient color		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

BOUNDS

A six-element floating-point vector of the form [x_{min} , y_{min} , z_{min} , x_{max} , y_{max} , z_{max}], which represents the sub-volume to be rendered. .

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Subvolume bounds		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

CLIP_PLANES

A 4-by- N floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where $Ax + By + Cz + D = 0$. Portions of this object that fall in the half space $Ax + By + Cz + D > 0$ will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

Note

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

Note

Clipping planes are applied in the data space of this object (prior to the application of any x , y , or z coordinate conversion).

Note

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

Note

Clipping planes are equivalent to the obsolete cutting planes. If defined, CUTTING_PLANES will be applied first, then the CLIP_PLANES (until a maximum number of planes is reached).

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

COMPOSITE_FUNCTION

An integer value or enumerated list item that determines the composite function to be used to measure the value of a pixel on the viewing plane by analyzing the voxels

falling along the corresponding ray. Specify one of the following compositing functions:

Value	Property Sheet Value	Description
0	Alpha blending	The recursive equation $\text{dest}' = \text{src} * \text{srcalpha} + \text{dest} * (1 - \text{srcalpha})$ is used to compute the final pixel color (the default).
1	Maximum intensity projection	The color of each pixel on the viewing plane is determined by the voxel with the highest opacity value along the corresponding ray.
2	Alpha sum	The recursive equation $\text{dest}' = \text{src} + \text{dest} * (1 - \text{srcalpha})$ is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.
3	Average intensity	The resulting image is the average of all voxels along the corresponding ray. Disables lighting and only works with grey scale palettes. Will not work with four-channel volumes.

Property Type	ENUMLIST		
Name String	Composite function		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DATA0

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA1, DATA2, or DATA3, all existing data is removed from the object. . See “[Note On Maximum Renderable Volume Size](#)” on page 4555 for additional details.

Specifying this property is the same as specifying the optional vol_0 argument to the `IDLgrVolume::Init` method.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA1

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA2, or DATA3, all existing data is removed from the object. See “[Note On Maximum Renderable Volume Size](#)” on page 4555 for additional details.

Specifying this property is the same as specifying the optional vol_1 argument to the `IDLgrVolume::Init` method.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA2

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA3, all existing data is removed from the object. See “[Note On Maximum Renderable Volume Size](#)” on page 4555 for additional details.

Specifying this property is the same as specifying the optional vol_2 argument to the [IDLgrVolume::Init](#) method.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DATA3

A three-dimensional array of any type of the format (d_x, d_y, d_z) , which specifies a data volume. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA2, all existing data is removed from the object. See “[Note On Maximum Renderable Volume Size](#)” on page 4555 for additional details.

Specifying this property is the same as specifying the optional vol_3 argument to the [IDLgrVolume::Init](#) method.

Note

DATA0, DATA1, DATA2, and DATA3 sizes are dynamic.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Property Type	Array of any type		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEPTH_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between Z_{bright} and Z_{dim} determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0].

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Depth cue range		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HIDE

A Boolean value or enumerated list item indicating whether this object should be drawn:

Value	Property Sheet Value	Description
0	True	Draw graphic (the default)
1	False	Do not draw graphic

Property Type	ENUMLIST		
Name String	Show		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HINTS

An integer value or enumerated list item that specifies one of the following acceleration hints:

Value	Property Sheet Value	Description
0	Disable	Disables all acceleration hints (the default).
1	Euclidean distance map (EDM)	Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.
2	Multiple CPU	Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
3	EDM and Multiple CPU	Selects the two acceleration options described above

Property Type	ENUMLIST		
Name String	Acceleration hints		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

INTERPOLATE

A Boolean value or enumerated list item that determines whether the interpolation method.

Value	Property Sheet Value	Description
0	Nearest neighbor	Values between the voxels are estimated using nearest neighbor sampling (the default).
1	Trilinear	Values for each step on a ray are computed from the eight nearest values. Setting this property improves quality at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane.

Note

See “[Interpolation Methods](#)” (Chapter 5, *Using IDL*) for details.

Property Type	ENUMLIST		
Name String	Interpolation		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

LIGHTING_MODEL

A Boolean value that determines whether to use the current lighting model during rendering in conjunction with a local gradient evaluation.

Note

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time.

Property Type	Boolean		
Name String	Use lighting		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

OPACITY_TABLE0

A 256-element byte array that specifies the opacity table for DATA0. The default table is the linear ramp.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPACITY_TABLE1

A 256-element byte array that specifies the opacity table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PARENT

An object reference to the object that contains this object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDER_STEP

A three-element floating-point vector of the form $[x, y, z]$ that specifies the stepping factor through the voxel matrix.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	XYZ render step		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

RGB_TABLE0

A 256 x 3-element byte array that specifies the RGB color table for DATA0. The default table is the linear ramp. .

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

RGB_TABLE1

A 256 x 3-element byte array that specifies the RGB color table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SHADER

An object reference to an [IDLgrShader](#) object (or an object containing IDLgrShader as a superclass). When there is suitable graphics card hardware support, the volume is rendered using the GLSL shader program (executed on the graphics card) instead of using fixed OpenGL properties when initially drawn. (If a suitable graphics card is not present, IDL ignores the shader object when the scene is drawn.) A single IDLgrShader object may be associated with additional volume objects or other graphic objects that have the SHADER property.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TWO_SIDED

A Boolean value or an enumerated list item that determines whether the lighting model uses a two-sided voxel gradient.

Value	Property Sheet Value	Description
0	One-sided	The default.
1	Two-sided	Differs from one-sided in that this method uses the absolute value of the inner product of the light direction and the surface gradient instead of clamping to 0.0 for negative values.

Property Type	ENUMLIST		
Name String	Voxel gradient		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VALID_DATA

An integer array (one per volume, DATA0, DATA1, etc.) which have the value 1 if volume data has been loaded for that volume and 0 if that volume data is currently undefined.

Property Type	Integer array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

VOLUME_SELECT

An integer value that selects how the volume data (DATA0, DATA1, DATA2, DATA3) is combined to form the src and srcalpha parameters described in the COMPOSITE_FUNCTION function property.

The volume data is always stored and treated as 8-bit indices into the RGB and opacity tables.

Set the RGB and/or opacity tables to linear ramps to use the volume data as direct color or opacity values. Accepted values are:

0	<p>Render single volume from DATA0. This is the default. The value at voxel [i,j,k] would be computed as:</p> <pre>srcRed[i,j,k] = RGB_TABLE0[DATA0[i,j,k],0] srcGreen[i,j,k] = RGB_TABLE0[DATA0[i,j,k],1] srcBlue[i,j,k] = RGB_TABLE0[DATA0[i,j,k],2] srcAlpha[i,j,k] = OPACITY_TABLE0[DATA0[i,j,k]]</pre>
1	<p>Render dual volume from DATA0 and DATA1. The value at voxel [i,j,k] is modulated between the two data sets as follows:</p> <pre>srcRed[i,j,k] = (RGB_TABLE0[DATA0[i,j,k],0] * RGB_TABLE1[DATA1[i,j,k],0]) / 255 srcGreen[i,j,k] = (RGB_TABLE0[DATA0[i,j,k],1] * RGB_TABLE1[DATA1[i,j,k],1]) / 255 srcBlue[i,j,k] = (RGB_TABLE0[DATA0[i,j,k],2] * RGB_TABLE1[DATA1[i,j,k],2]) / 255 srcAlpha[i,j,k] = (OPACITY_TABLE0[DATA0[i,j,k]] * OPACITY_TABLE1[DATA1[i,j,k]]) / 255</pre>
2	<p>Render RGBA volume from DATA0 (red), DATA1 (green), DATA2 (blue), and DATA3 (alpha). The value at voxel [i,j,k] would be computed as:</p> <pre>srcRed[i,j,k] = RGB_TABLE0[DATA0[i,j,k],0] srcGreen[i,j,k] = RGB_TABLE0[DATA1[i,j,k],1] srcBlue[i,j,k] = RGB_TABLE0[DATA2[i,j,k],2] srcAlpha[i,j,k] = OPACITY_TABLE0[DATA3[i,j,k]]</pre>

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedX} = s_0 + s_1 * \text{DataX}$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}), 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

XRANGE

A two-element double-precision floating-point vector of the form [x_{min} , x_{max}] that specifies the range of x data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

YCOORD_CONV

A floating-point vector, [s_0 , s_1], of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedY} = s_0 + s_1 * \text{DataY}$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}), 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

YRANGE

A two-element double-precision floating-point vector of the form $[ymin, ymax]$ that specifies the range of y data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZBUFFER

A Boolean value that determines whether to clip the rendering to the current Z-buffer and then update the buffer. The default is to not modify the current Z-buffer.

Property Type	Boolean		
Name String	Update Z buffer		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}), 1/(Z_{max}-Z_{min})]$$

The default is $[0.0, 1.0]$ IDL converts, maintains, and returns this data as double-precision floating-point.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZERO_OPACITY_SKIP

A Boolean value that determines whether to skip voxels with an opacity of 0. This property can increase the output contrast of MIP (MAXIMUM_INTENSITY) projections by allowing the background to show through. If this property is set,

voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the property) continues to render voxels with an opacity of zero.

Property Type	Boolean		
Name String	Skip zero opacity		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrVolume::Cleanup

The IDLgrVolume::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrVolume::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrVolume::ComputeBounds

The IDLgrVolume::ComputeBounds procedure method computes the smallest bounding box that contains all voxels whose opacity lookup is greater than a given opacity value. The BOUNDS property is updated to the computed bounding box.

Syntax

```
Obj->[IDLgrVolume::]ComputeBounds [, OPACITY=value] [, /RESET]
      [, VOLUMES=int array]
```

Arguments

None

Keywords

OPACITY

Set this keyword to the opacity value to be used to determine which voxels are included within the bounding box. All voxels whose opacity lookup is greater than this value will be included. The default value is zero.

RESET

Set this keyword to cause the BOUNDS keyword of IDLgrVolume::Init to be reset to contain the entire volume.

VOLUMES

Set this keyword to an array of integers which select which volumes to consider when computing the bounding box. A non-zero value selects a volume to be searched. The default is to search all loaded volumes. For example: VOLUMES=[0,1] will cause ComputeBounds to search only the volume loaded in DATA1.

Version History

5.0	Introduced
-----	------------

IDLgrVolume::GetCTM

The IDLgrVolume::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Syntax

```
Result = Obj->[IDLgrVolume::]GetCTM( [, DESTINATION=objref]  
    [, PATH=objref(s)] [, TOP=objref to IDLgrModel object] )
```

Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

Arguments

None

Keywords

DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the volume object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVolume::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

TOP

Set this keyword equal to the object reference to an [IDLgrModel](#) object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

Version History

5.0	Introduced
-----	------------

IDLgrVolume::GetProperty

The IDLgrVolume::GetProperty procedure method retrieves the value of a property or group of properties for the volume.

Syntax

```
Obj->[IDLgrVolume::]GetProperty[, PROPERTY=variable] [, /NO_COPY]
```

Arguments

None

Keywords

Any property listed under “[IDLgrVolume Properties](#)” on page 4530 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

NO_COPY

If this keyword is set to a non-zero value, and the [DATA0](#), [DATA1](#), [DATA2](#), or [DATA3](#) property is specified in the same invocation, the data is relocated from the volume object into the destination variable, removing the data from the object.

```
vol = BYTARR(30,30,30, /NOZERO)
oVol = OBJ_NEW('IDLgrVolume')
oVol->SetProperty, DATA0=vol

oVol->GetProperty, DATA0=vol, /NO_COPY
HELP, vol
; IDL prints VOL BYTE = Array[30, 30, 30]

; Verify that the data has been removed from the object by
; repeating the call.
oVol->GetProperty, DATA0=vol2, /NO_COPY
HELP, vol2
; IDL prints VOL2 UNDEFINED = <Undefined>
```

There can be 1, 2, 3, or 4 volumes stored in an IDLgrVolume. Calling Get with NO_COPY is a good way to remove the data associated with one of the volumes without destroying the object.

Version History

5.0	Introduced
6.1	Added NO_COPY keyword

IDLgrVolume::Init

The IDLgrVolume::Init function method initializes the volume object. At least one volume must be specified, via arguments or keywords.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Note

IDL converts and stores volume data in a BYTE array. Thus, all incoming volume data is converted to BYTE type. This could alter the volume data values if the incoming data cannot accurately be stored as BYTE data.

Syntax

```
Obj = OBJ_NEW('IDLgrVolume' [, vol0 [, vol1 [, vol2 [, vol3]]]]
      [, PROPERTY=value] [, /NO_COPY])
```

or

```
Result = Obj->[IDLgrVolume::]Init([vol0 [, vol1 [, vol2 [, vol3]]]]
      [, PROPERTY=value] [, /NO_COPY]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Note

The values specified by the *vol₀*, *vol₁*, *vol₂*, and *vol₃* arguments are used to initialize the values of the [DATA0](#), [DATA1](#), [DATA2](#), and [DATA3](#) properties of the IDLgrVolume object, respectively.

vol₀

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol₁

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol₂

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

vol₃

A three-dimensional array (d_x, d_y, d_z) which specifies a data volume.

Note

If two or more of the above arguments are specified, they must have matching dimensions.

Note On Maximum Renderable Volume Size

On 64-bit platforms, each dimension (d_x, d_y, d_z) of the volume can contain up to a maximum of 2^{32} elements, with a limit of 2^{64} total voxels. On 32-bit platforms, the volume can contain a maximum of 2^{32} voxels.

Keywords

Any property listed under “[IDLgrVolume Properties](#)” on page 4530 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

NO_COPY

If this keyword is set to a non-zero value, it relocates the volume data from the input variable to the volume object, leaving the input variable (*vol₀*, *vol₁*, *vol₂*, *vol₃*, or [DATA0](#), [DATA1](#), [DATA2](#), or [DATA3](#)) undefined. Only these data-related arguments and properties are affected by the NO_COPY keyword.

```
vol = BYTARR(30,30,30, /NOZERO)
oVol = OBJ_NEW('IDLgrVolume', vol, /NO_COPY)
```

```
; Verify the data no longer exists in the input variable.
```

```
HELP, vol  
; IDL prints VOL UNDEFINED = <Undefined>
```

If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrVolume::PickVoxel

The IDLgrVolume::PickVoxel function method computes the coordinates of the voxel projected to a location specified by the 2-D device coordinates point, $[x_i, y_i]$, and the current Z-buffer. The function returns the volume indices as a vector of three long integers. If the selected point is not within the volume, this function returns $[-1,-1,-1]$.

Syntax

Result = *Obj*->[IDLgrVolume::]PickVoxel (*Win*, *View*, *Point* [, **PATH**=*objref(s)*])

Return Value

Returns the volume indices as a vector of three long integers. If the selected point is not within the volume, this function returns $[-1,-1,-1]$.

Arguments

Win

The [IDLgrWindow](#) object from which the Z-buffer is to be used.

View

The IDLgrView object that contains the volume.

Point

The $[x, y]$ viewport coordinates of the point chosen.

Keywords

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a voxel coordinate. Each path object reference specified with this keyword must contain an alias. The voxel coordinate is computed for the version of the object falling within the specified path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

5.0	Introduced
-----	------------

IDLgrVolume:: SetProperty

The IDLgrVolume::SetProperty procedure method sets the value of a property or group of properties for the volume.

Syntax

Obj->[IDLgrVolume::]SetProperty[, *PROPERTY=value*] [/NO_COPY]

Arguments

None

Keywords

Any property listed under “IDLgrVolume Properties” on page 4530 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

NO_COPY

If this keyword is set to a non-zero value, it relocates the volume data from the input variable to the volume object, leaving the input variable ([DATA0](#), [DATA1](#), [DATA2](#), or [DATA3](#)) undefined. Only these data-related arguments and properties are affected by the NO_COPY keyword.

```
vol = BYTARR(30,30,30, /NOZERO)
oVol = OBJ_NEW('IDLgrVolume')
oVol->SetProperty, Data0=vol, /NO_COPY

; Verify that the data has been removed from the variable.
HELP, vol
; IDL prints VOL UNDEFINED = <Undefined>
```

If this keyword is omitted, the input volume data will be duplicated and a copy will be stored in the object.

Version History

5.0	Introduced
6.2	Added NO_COPY keyword

IDLgrVRML

The IDLgrVRML object allows you to save the contents of an Object Graphics hierarchy into a VRML 2.0 format file. The graphics tree can only contain a single view due to limitations in the VRML specification. The resulting VRML file is interactive and allows you to explore the geometry interactively using a VRML browser.

Note

Objects or subclasses of this type can not be saved or restored.

Note

Tiled images are not supported on IDLgrVRML.

Aspect ratios are difficult to duplicate as they can be browser dependent. The object is limited to the primitives supported by VRML. Texture maps (and images) will be inlined into the output file. While this will generate large VRML files, the files are fully self-contained.

Several entities cannot be translated perfectly. These include:

IDLgrImage Objects

Rotation and Z buffer behavior are not completely supported. Image objects will be converted into texture mapped polygons. BLEND_FUNCTION is not completely supported (only binary srcAlpha,1-srcAlpha) This function is applied automatically if an alpha channel is present. It is also very browser dependent. Channel masks are not supported.

IDLgrPolygon and IDLgrSurface Objects

Hidden line/hidden point display, color and vertex color blending with texture colors, and bottom color are not supported. Shading may be browser dependent. Front face culling is not supported and back face culling is only supported at the browser's discretion.

Note

The AMBIENT material property is not supported.

IDLgrLight Objects

Lighting scope and intensity may be browser dependent.

IDLgrText Objects

Text using the ONGLASS property is only supported for the initial view.

IDLgrViewgroup, IDLgrScene, IDLgrVolume Objects

These objects are not supported.

IDLgrPalette Objects

Palette objects are simulated using an RGB color model.

IDLgrPattern Objects

Only solid or clear patterns are supported.

IDLgrFont, IDLgrSymbol Objects

The THICK property is not supported.

IDLgrPolyline, IDLgrSymbol, IDLgrSurface, IDLgrPolygon and IDLgrPlot Objects

Line attributes (thickness, linestyle) are not supported.

IDLgrView Objects

Z-clipping control, aspect ratio preservation, the LOCATION property, and orthographic projections are not supported.

Destination Objects

The COLOR_MODEL property is not fully supported in Indexed Color mode, when using a SHADER_RANGE (an RGB model will be substituted instead). The QUALITY property is not supported.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrVRML::Init](#)” on page 4580.

Properties

Objects of this class have the following properties. See “[IDLgrVRML Properties](#)” on page 4565 for details on individual properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [GRAPHICS_TREE](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)
- [WORLDINFO](#)
- [WORLDTITLE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLgrVRML::Cleanup](#)
- [IDLgrVRML::Draw](#)
- [IDLgrVRML::GetDeviceInfo](#)
- [IDLgrVRML::GetFontnames](#)
- [IDLgrVRML::GetProperty](#)
- [IDLgrVRML::GetTextDimensions](#)
- [IDLgrVRML::Init](#)

- [IDLgrVRML::SetProperty](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.1	Introduced
-----	------------

IDLgrVRML Properties

IDLgrVRML objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrVRML::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrVRML::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrVRML::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [FILENAME](#)
- [GRAPHICS_TREE](#)
- [N_COLORS](#)
- [PALETTE](#)
- [QUALITY](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)
- [WORLDINFO](#)
- [WORLDTITLE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value or enumerated list item that determines the color model for the buffer:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color indexed

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the window in units specified by the UNITS property. The default is [640,480].

Note

The only use of this property is to support the use of normalized coordinates for the dimensions of the IDLgrView object passed to the IDLgrVRML::Draw method.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FILENAME

A string that specifies the name of a file into which the vector data will be saved. The default is `idl.wr1`.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

GRAPHICS_TREE

An object reference of type `IDLgrView`. If this property is set to a valid object reference, calling the `Draw` method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the `GRAPHICS_TREE` property is set equal to the null-object. .

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer that specifies the number of colors (between 2 and 256) to be used if `COLOR_MODEL` is set to `indexed`.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the `IDLgrPalette` object class) that specifies the red, green, and blue values that are to be loaded into the buffer's color lookup table.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrVRML object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer value or enumerated list item indicating the rendering quality at which graphics are to be drawn to the buffer:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RESOLUTION

A two-element floating-point vector of the form $[xres, yres]$ specifying the device resolution in centimeters per pixel.

Note

This property is used for text scaling and partial aspect ratio preservation only. The default value is $[0.0352778, 0.0352778]$ (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Resolution		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element integer vector of the form $[width, height]$ specifying the dimensions of the overall screen dimensions for the screen with which this object associated. The screen dimensions are measured in device units.

Property Type	Integer vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

UNITS

An integer that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (the default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

WORLDINFO

A list of strings for the info field of the VRML WorldInfo node. The default is the null string, "".

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

WORLDTITLE

A string containing the title for the VRML WorldInfo node, TITLE field. The default is 'IDL VRML file'.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLgrVRML::Cleanup

The IDLgrVRML::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrVRML::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrVRML::Draw

The IDLgrVRML::Draw procedure method draws the given picture to this graphics destination.

Syntax

Obj->[IDLgrVRML::]Draw [, *Picture*]

Arguments

Picture

The view (an instance of an [IDLgrView](#) object) to be drawn. If the view has a LOCATION property, it is ignored.

Keywords

None

Version History

5.1	Introduced
-----	------------

IDLgrVRML::GetDeviceInfo

The IDLgrVRML::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrVRML::]GetDeviceInfo [, ALL=variable]
    [, MAX_NUM_CLIP_PLANES=variable]
    [, MAX_TEXTURE_DIMENSIONS=variable]
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]
    [, NUM_CPUS=variable] [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_TEXTURE_DIMENSIONS* contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_VIEWPORT_DIMENSIONS* contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, *NAME* contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, *NUM_CPUS* contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The *NUM_CPUS* keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

VENDOR

Set this keyword equal to a named variable. Upon return, *VENDOR* contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, *VERSION* contains the version of the rendering device driver as a string.

Version History

5.1	Introduced
5.6	Added <i>MAX_NUM_CLIP_PLANES</i> keyword

IDLgrVRML::GetFontnames

The IDLgrVRML::GetFontnames function method returns the list of available fonts that can be used in [IDLgrFont](#) objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrVRML::]GetFontnames( FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

Return Value

Returns the list of available fonts that can be used in [IDLgrFont](#) objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name, such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as “Bold Italic”. If you set STYLES to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.1	Introduced
-----	------------

IDLgrVRML::GetProperty

The IDLgrVRML::GetProperty procedure method retrieves the value of a property or group of properties for the VRML object.

Syntax

Obj->[IDLgrVRML::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrVRML Properties” on page 4565 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.1	Introduced
-----	------------

IDLgrVRML::GetTextDimensions

The IDLgrVRML::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the IDLgrText `RECOMPUTE_DIMENSIONS` property.

Syntax

```
Result = Obj->[IDLgrVRML::]GetTextDimensions( TextObj [, DESCENT=variable]
[, PATH=objref(s)] )
```

Return Value

Returns a 3-element double-precision floating-point vector $[xDim, yDim, zDim]$ representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrVRML::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

5.1	Introduced
-----	------------

IDLgrVRML::Init

The IDLgrVRML::Init function method initializes the VRML object. This creates an object that will convert object hierarchies rendered to it into VRML format files.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDLgrVRML' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrVRML::]Init([, *PROPERTY=value*]) *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLgrVRML Properties” on page 4565 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

Version History

5.1	Introduced
-----	------------

IDLgrVRML:: SetProperty

The IDLgrVRML:: SetProperty procedure method sets the value of a property or group of properties for the VRML world.

Syntax

Obj->[IDLgrVRML::] SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “IDLgrVRML Properties” on page 4565 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.1	Introduced
-----	------------

IDLgrWindow

A window object is a representation of an on-screen area on a display device that serves as a graphics destination.

Note

Objects or subclasses of this type can not be saved or restored.

Note on Window Size Limits

The OpenGL libraries IDL uses impose limits on the maximum size of a drawable area. The limits are device-dependent — they depend both on your graphics hardware and the setting of the RENDERER property. Currently, the smallest maximum drawable area on any IDL platform is 1280 x 1024 pixels; the limit on your system may be larger.

Superclasses

[IDLitComponent](#)

Creation

See “[IDLgrWindow::Init](#)” on page 4617.

Properties

Objects of this class have the following properties. See “[IDLgrWindow Properties](#)” on page 4586 for details on individual properties.

- ZBUFFER_DATA
- ZOOM_NSTEP
- TITLE
- VIEWPORT_DIMENSIONS
- VISIBLE_LOCATION
- ZOOM_BASE

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- IDLgrWindow::Cleanup
- IDLgrWindow::Draw
- IDLgrWindow::Erase
- IDLgrWindow::GetContiguousPixels
- IDLgrWindow::GetDeviceInfo
- IDLgrWindow::GetDimensions
- IDLgrWindow::GetFontnames
- IDLgrWindow::GetProperty
- IDLgrWindow::GetTextDimensions
- IDLgrWindow::Iconify
- IDLgrWindow::Init
- IDLgrWindow::OnEnter
- IDLgrWindow::OnExit
- IDLgrWindow::OnExpose
- IDLgrWindow::OnKeyboard
- IDLgrWindow::OnMouseDown
- IDLgrWindow::OnMouseMove
- IDLgrWindow::OnMouseUp
- IDLgrWindow::OnResize

- [IDLgrWindow::OnWheel](#)
- [IDLgrWindow::PickData](#)
- [IDLgrWindow::QueryRequiredTiles](#)
- [IDLgrWindow::Read](#)
- [IDLgrWindow::Select](#)
- [IDLgrWindow::SetCurrentCursor](#)
- [IDLgrWindow::SetCurrentZoom](#)
- [IDLgrWindow::SetProperty](#)
- [IDLgrWindow::Show](#)
- [IDLgrWindow::ZoomIn](#)
- [IDLgrWindow::ZoomOut](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced.
6.1	Added <code>MINIMUM_VIRTUAL_DIMENSIONS</code> , <code>ZOOM_BASE</code> , and <code>ZOOM_NSTEP</code> properties.
6.2	Added <code>QueryRequiredTiles</code> method. Added <code>VIEWPORT_DIMENSIONS</code> property.
6.3	Added <code>OnEnter</code> , <code>OnExit</code> , <code>OnExpose</code> , <code>OnKeyboard</code> , <code>OnMouseDown</code> , <code>OnMouseMove</code> , <code>OnMouseUp</code> , and <code>OnResize</code> methods.
6.4	Added <code>OnWheel</code> method.

IDLgrWindow Properties

IDLgrWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLgrWindow::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLgrWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLgrWindow::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [ALL](#)
- [CURRENT_ZOOM](#)
- [DISPLAY_NAME \(X Only\)](#)
- [IMAGE_DATA](#)
- [MINIMUM_VIRTUAL_DIMENSIONS](#)
- [PALETTE](#)
- [REGISTER_PROPERTIES](#)
- [RESOLUTION](#)
- [SCREEN_DIMENSIONS](#)
- [UNITS](#)
- [VIRTUAL_DIMENSIONS](#)
- [ZBUFFER_DATA](#)
- [ZOOM_NSTEP](#)
- [COLOR_MODEL](#)
- [DIMENSIONS](#)
- [GRAPHICS_TREE](#)
- [LOCATION](#)
- [N_COLORS](#)
- [QUALITY](#)
- [RENDERER](#)
- [RETAIN](#)
- [TITLE](#)
- [VIEWPORT_DIMENSIONS](#)
- [VISIBLE_LOCATION](#)
- [ZOOM_BASE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

Note

The fields of this structure may change in subsequent releases of IDL.

Property Type	Structure		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COLOR_MODEL

An integer value or enumerated list item that determines the color model for the window:

Value	Property Sheet Value	Description
0	RGB	RGB (default)
1	Indexed	Color indexed

Note

For some X11 display situations, IDL may not be able to support a color index model destination object in object graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations.

Property Type	ENUMLIST		
Name String	Color model		
Get: Yes	Set: No	Init: Yes	Registered: Yes

CURRENT_ZOOM

A floating-point value that represents the current zoom factor associated with this window.

Property Type	FLOAT		
Name String	Zoom factor		
Get: Yes	Set: No	Init: No	Registered: Yes

DIMENSIONS

A two-element integer vector of the form $[width, height]$ to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the values of the [IDL_GR_WIN_HEIGHT](#) and [IDL_GR_WIN_WIDTH](#) preferences (under Microsoft Windows) or the values of the [IDL_GR_X_HEIGHT](#) and [IDL_GR_X_WIDTH](#) preferences (under UNIX). There are limits on the maximum size of an IDLgrWindow object; see “[Note on Window Size Limits](#)” on page 4583 for details.

Note

Changing the DIMENSIONS property is merely a request to the windowing system and may be ignored.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DISPLAY_NAME (X Only)

A string that specifies the name of the X Windows display on which the window is to appear.

Property Type	STRING		
Name String	Display name		
Get: Yes	Set: Yes	Init: No	Registered: Yes

GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView describing the graphics tree of this window object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

Property Type	Object reference		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMAGE_DATA

A byte array representing the image that is currently displayed in the window. If the window object uses an RGB color model, the returned array will have dimensions (3, *winXSize*, *winYSize*), or (4, *winXSize*, *winYSize*) if an alpha channel is included. If the window object uses an Indexed color model, the returned array will have dimensions (*winXSize*, *winYSize*). See “IDLgrWindow::Read” on page 4642 for more information.

Property Type	Byte array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

LOCATION

A two-element floating-point vector of the form [x, y] to specify the location of the upper lefthand corner of the window relative to the display screen, in units specified by the UNITS property. The default value for the LOCATION property is [0,0].

About Multi-Monitor Configurations and LOCATION

If explicit window dimensions are not specified and the IDL_GR_WIN_QSCREEN or IDL_GR_X_QSCREEN preference is set to true, IDL will use the size of the monitor on which the window will be created to calculate the dimensions of a window 1/4 the screen size. In multi-monitor configurations, if a window's LOCATION property does not specify a value that is on any monitor, IDL uses the size of the monitor containing the location [0,0] for the 1/4 screen calculation.

Additionally, some window managers and desktop systems may override application-specified window locations. Therefore, a window may not always be positioned at the location specified by the LOCATION property.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

MINIMUM_VIRTUAL_DIMENSIONS

A two-element vector, [*width*, *height*], specifying the minimum dimensions allowed for the virtual canvas of this window. The unit of measure is specified by the UNITS property. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default value of this property is [0, 0], a value indicating that the minimum virtual dimensions should match the current virtual dimensions.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

N_COLORS

An integer value that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Indexed (1). This property is ignored if COLOR_MODEL is set to RGB (0).

Note

If COLOR_MODEL is set to Color Index (1), setting N_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the [IDLgrWindow::GetProperty](#) method. The actual number of available colors depends on your system and also on how you have used IDL.

Property Type	Integer		
Name String	Number of colors		
Get: Yes	Set: No	Init: Yes	Registered: Yes

PALETTE

An object reference to a palette object (an instance of the [IDLgrPalette](#) object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table, applicable if the Indexed color model is used.

Note

Objects specified via this property are not automatically cleaned up when the IDLgrWindow object is destroyed.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Color palette		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

QUALITY

An integer value or enumerated list item indicating the rendering quality with which graphics are to be drawn to this destination. Valid values are:

Value	Property Sheet Value	Description
0	Low	Low quality
1	Medium	Medium quality
2	High	High quality (the default)

Property Type	ENUMLIST		
Name String	Draw quality		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. If this property is set, all properties marked in this properties section as “Registered: Yes” will be registered for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

RENDERER

An integer value or enumerated list item indicating which graphics renderer to use when drawing objects within the window. Valid values are:

Value	Property Sheet Value	Description
0	OpenGL	Uses platform native OpenGL
1	Software	Uses IDL’s software implementation

By default, IDL uses the renderer specified by the [IDL_GR_WIN_RENDERER](#) (Windows) or [IDL_GR_X_RENDERER](#) (UNIX) preference. If your platform does not have a native OpenGL implementation, IDL uses its own software implementation regardless of the value of this property. See “[Hardware vs. Software Rendering](#)” (Chapter 2, *Object Programming*) for details. Your choice of renderer may also affect the maximum size of an IDLgrWindow object; see “[Note on Window Size Limits](#)” on page 4583 for details.

Property Type	ENUMLIST		
Name String	Renderer		
Get: Yes	Set: No	Init: Yes	Registered: Yes

RESOLUTION

A floating-point vector of the form [*xres*, *yres*] reporting the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

Property Type	FLOAT		
Name String	Resolution		
Get: Yes	Set: No	Init: No	Registered: Yes

RETAIN

An integer value that specifies how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the “Backing Store” preference set in the IDL Workbench’s **Preferences** dialog. If there is no preference file for the Workbench (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

Value	Property Sheet Value	Description
0	No backing	No backing store.
1	Server/Window	The server or window system is requested to provide the backing store. Note - Requesting backing store from the server is only a request; backing store may not be provided in all situations
2	IDL	Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN property of IDLgrWindow::GetProperty . IDL may also alter the RENDERER property while attempting to provide backing store.

In IDL Object Graphics, it is almost always best to disable backing store (that is, set the RETAIN property equal to zero). This is because drawing to an off-screen pixmap

(which is what happens when backing store is enabled) almost always bypasses any hardware graphics acceleration that may be available, causing all rendering to be done in software. To ensure that windows are redrawn properly, enable the generation of expose events on the WIDGET_DRAW window and redraw the window explicitly when an expose event is received.

Note

On Macintosh and Microsoft Windows systems, if you are using software rendering (that is, the RENDERER property is set equal to one), IDL will refresh the window automatically regardless of the setting of the RETAIN property.

Property Type	ENUMLIST		
Name String	Retain		
Get: Yes	Set: No	Init: Yes	Registered: Yes

SCREEN_DIMENSIONS

A two-element floating-point vector of the form [*width, height*] specifying the dimensions of the overall screen dimensions for the screen with which this window is associated. The screen dimensions are measured in device units.

Note

The maximum screen dimension size depends on the graphics device.

On multi-monitor configurations, this SCREEN_DIMENSIONS returns information for the primary monitor only. For information about other monitors, use the [IDLsysMonitorInfo](#) object.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

TITLE

A string that represents the title of the window.

Property Type	STRING		
Name String	Title		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

UNITS

An integer value or enumerated list item that specifies the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

Value	Property Sheet Value	Description
0	Device	Device units (the default)
1	Inches	Inches
2	Centimeters	Centimeters
3	Normalization	Normalized units (relative to the dimensions of the primary monitor/screen, as stored in the SCREEN_DIMENSIONS property)

Note

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units.

Property Type	ENUMLIST		
Name String	Units		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VIEWPORT_DIMENSIONS

A two-element floating-point vector of the form $[width, height]$ specifying the dimensions of the *viewport* of the draw widget that contains this window. If the window is not within a draw widget, this property is equivalent to the DIMENSIONS property.

Property Type	Floating-point vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

VIRTUAL_DIMENSIONS

A two-element integer vector, $[width, height]$, specifying the dimensions of the *virtual canvas* for this window. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default is $[0,0]$, indicating that the virtual canvas dimensions should match the visible dimensions (as specified via the DIMENSIONS property).

Note

When a drawable window is created using the WIDGET_DRAW function with the GRAPHICS_LEVEL keyword set equal to 2, the *width* and *height* values are initialized using the values of the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords to WIDGET_DRAW.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Virtual dimensions		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

VISIBLE_LOCATION

A two-element integer vector, $[x,y]$, specifying the lower left location of the visible portion of the canvas (relative to the virtual canvas). In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time.

This property is registered as a user-defined property, but it is hidden by default.

Property Type	USERDEF		
Name String	Visible location		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

Property Type	Floating-point array		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ZOOM_BASE

A floating point value representing the base value by which the window's current zoom factor will be multiplied or divided for zooming in or zooming out. Allowable values are those greater than 1.0. The default is 2.0.

Property Type	Float		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ZOOM_NSTEP

A named variable that, upon return, will contain an integer that indicates the number of times this window's ZOOM_BASE property has been applied to achieve the current zoom factor. A positive value indicates that the current zoom factor represents the result of zooming in ZOOM_NSTEP times. A negative value indicates that the current zoom factor represents the result of zooming out ZOOM_NSTEP times.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLgrWindow::Cleanup

The IDLgrWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLgrWindow::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrWindow::Draw

The `IDLgrWindow::Draw` procedure method draws the specified scene or view object to this graphics destination.

Note

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

Syntax

```
Obj->[IDLgrWindow::]Draw [, Picture] [, CREATE_INSTANCE={1 | 2}]
    [, DRAW_INSTANCE={1 | 2}]
```

Arguments

Picture

The view (an instance of an [IDLgrView](#) object), viewgroup (an instance of an `IDLgrViewgroup` object), or scene (an instance of an [IDLgrScene](#) object) to be drawn. If *Picture* is not supplied, the graphics hierarchy specified by the [GRAPHICS_TREE](#) property of the `IDLgrWindow` object will be drawn, if it exists. If neither the *Picture* argument or the `GRAPHICS_TREE` property are specified, nothing is drawn.

Keywords

CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

DRAW_INSTANCE

Set this keyword to specify that the instance, or unchanging part of the drawing, is drawn to the device first. IDL then draws the changing part of the drawing, indicated by the scene, view or viewgroup specified by the *Picture* argument.

If the value of this keyword is 1, IDL copies both the instance image (color buffer) and the instance depth buffer to the device.

If the value of this keyword is 2, IDL copies only the instance image to the device.

Note

Set the `TRANSPARENT` property of any `IDLgrView` objects associated with the *Picture* argument to a non-zero value before calling the `Draw` method with the `DRAW_INSTANCE` keyword set. This prevents the drawn instance (the unchanging part of the scene) from being erased when drawing the changing portion of the scene contained in the *Picture* argument.

Version History

5.0	Introduced
-----	------------

IDLgrWindow::Erase

The IDLgrWindow::Erase procedure method erases the entire contents of the window and initializes the depth buffer.

Syntax

Obj->[IDLgrWindow::]Erase [, COLOR=*index or RGB vector*]

Arguments

None

Keywords

COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as a three-element vector [*red, green, blue*]. The default erase color is white.

Version History

5.0	Introduced
-----	------------

IDLgrWindow::GetContiguousPixels

The `IDLgrWindow::GetContiguousPixels` function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the `N_COLORS` property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the `SHADE_RANGE` property of the [IDLgrSurface](#) and [IDLgrPolygon](#) object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj->GetContiguousPixels()  
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0, 1, 2, 3, 4]  
[4, 3, 2, 1, 0]
```

Syntax

```
Result = Obj->[IDLgrWindow::]GetContiguousPixels()
```

Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrWindow::GetDeviceInfo

The IDLgrWindow::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=0 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

Syntax

```
Obj->[IDLgrWindow::]GetDeviceInfo [, ALL=variable]
    [, FRAMEBUFFER_OBJECT_EXTENSION=variable]
    [, MAX_FRAGMENT_UNIFORM_COMPONENTS=variable]
    [, MAX_NUM_CLIP_PLANES=variable]
    [, MAX_TEXTURE_DIMENSIONS=variable]
    [, MAX_TILE_DIMENSIONS=variable]
    [, MAX_TEXTURE_IMAGE_UNITS=variable]
    [, MAX_VERTEX_ATTRIBUTES=variable]
    [, MAX_VERTEX_TEXTURE_IMAGE_UNITS=variable]
    [, MAX_VERTEX_UNIFORM_COMPONENTS=variable]
    [, MAX_VIEWPORT_DIMENSIONS=variable] [, NAME=variable]
    [, NUM_CPUS=variable] [, SHADING_LANGUAGE_VERSION=variable]
    [, VENDOR=variable] [, VERSION=variable]
```

Arguments

None

Keywords

ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

FRAMEBUFFER_OBJECT_EXTENSION

Set this keyword to a named variable that will indicate whether the graphics card and OpenGL driver support the GLSL `framebuffer_object_extension`, which is

required for [IDLgrFilterChain](#) object support and image caching (using [IDLgrShader](#)'s [CACHE_RESULT](#) property):

0	No support for chaining shaders or caching
1	Support for chaining shaders and caching

MAX_FRAGMENT_UNIFORM_COMPONENTS

Set this keyword to a named variable that will contain the maximum number of components, or storage units, declared by active uniform variables in a fragment shader program. For example, a uniform variable of GLSL vector variable type `vec2` uses 2 components. This value is zero for devices that do not support shader programs, implemented using the [IDLgrShader](#) object.

MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, `MAX_TEXTURE_DIMENSIONS` contains a two element integer array that specifies the maximum texture size supported by the device.

MAX_TEXTURE_IMAGE_UNITS

Set this keyword to a named variable that will contain the number of texture units available to the fragment shader program. This value is zero for devices that do not support shader programs, implemented using the [IDLgrShader](#) object.

MAX_TILE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, `MAX_TILE_DIMENSIONS` contains a two element integer array that specifies the maximum tile size supported by the device.

MAX_VERTEX_ATTRIBUTES

Set this keyword to a named variable that will contain the maximum number of positions available for GLSL vertex attribute variables associated with a shader program. Each shader program attribute variable occupies one position, except for

GLSL matrix attribute variables of type `mat2`, `mat3`, and `mat4`, which occupy 2, 3, and 4 attribute variable positions, respectively. This value is zero for devices that do not support shader programs, implemented using the [IDLgrShader](#) object.

Note

IDL always uses one vertex attribute variable. The value reported by the `MAX_VERTEX_ATTRIBUTES` property is the number of positions that remain after deducting the variable used by IDL. Thus, if the graphics hardware provides 16 slots for vertex attribute variables, this property will report 15 available slots.

MAX_VERTEX_TEXTURE_IMAGE_UNITS

Set this keyword to a named variable that will contain the maximum number of texture units available to the vertex shader program. This value is zero for devices that do not support vertex shader texture units.

MAX_VERTEX_UNIFORM_COMPONENTS

Set this keyword to a named variable that will contain the maximum number of components, or storage units, declared by active uniform variables in a vertex shader program. For example, a uniform variable of GLSL vector type `vec2` uses 2 components. This value is zero for devices that do not support shader programs, implemented using the [IDLgrShader](#) object.

MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, `MAX_VIEWPORT_DIMENSIONS` contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

NAME

Set this keyword equal to a named variable. Upon return, `NAME` contains the name of the rendering device as a string.

NUM_CPUS

Set this keyword equal to a named variable. Upon return, `NUM_CPUS` contains an integer that specifies the number of CPUs that are known to, and available to IDL.

Note

The NUM_CPUS keyword accurately returns the number of CPUs for the SUN and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

SHADING_LANGUAGE_VERSION

Set this keyword to a named variable that will contain a string indicating the version of OpenGL Shading Language (GLSL) supported by the system's graphic card. The string is of the form:

```
<version number><space><vendor-specific information>
```

where the version number is defined as

```
majorVersionNumber.minorVersionNumber
```

or

```
majorVersionNumber.minorVersionNumber.releaseNumber
```

This value is the empty string for devices that do not support shader programs, implemented using [IDLgrShader](#). For information on the level of support needed by the IDLgrShader object, see [“Hardware Requirements for Shaders”](#) (Chapter 14, *Object Programming*).

VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

Version History

5.0	Introduced
5.6	Added MAX_NUM_CLIP_PLANES keyword

6.2	Added MAX_TILE_DIMENSIONS keyword
6.4	Added FRAMEBUFFER_OBJECT_EXTENSION, MAX_FRAGMENT_UNIFORM_COMPONENTS, MAX_TEXTURE_IMAGE_UNITS, MAX_VERTEX_ATTRIBUTES, MAX_VERTEX_TEXTURE_IMAGE_UNITS, MAX_VERTEX_UNIFORM_COMPONENTS, and SHADING_LANGUAGE_VERSION keywords

IDLgrWindow::GetDimensions

The IDLgrWindow::GetDimensions function method returns a two-element vector, [*width*, *height*], representing the visible dimensions (in pixel units) of this window.

Syntax

```
Result = Obj -> [IDLgrWindow::]GetDimensions
  ( [, MINIMUM_VIRTUAL_DIMENSIONS=variable]
    [, ORIGINAL_VIRTUAL_DIMENSIONS=variable]
    [, VIRTUAL_DIMENSIONS=variable] [, VISIBLE_LOCATION=variable])
```

Return Value

Returns the visible dimensions of the window (in pixel units) in a two-element vector [*width*, *height*].

Arguments

None

Keywords

MINIMUM_VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the minimum allowed virtual dimensions for this window.

Note

Returning MINIMUM_VIRTUAL_DIMENSIONS using GetDimensions provides the width and height of the window in pixel units. The property, “[MINIMUM_VIRTUAL_DIMENSIONS](#)” on page 4590, returns the dimensions of the window in units specified by the UNITS property.

ORIGINAL_VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the virtual dimensions in pixels for this window if the current zoom factor was 1.0.

VIRTUAL_DIMENSIONS

Set this keyword to a named variable that will contain a two-element vector, [*width*, *height*], representing the dimensions in pixels of the virtual canvas for this window.

VISIBLE_LOCATION

Set this keyword to a named variable that will contain a two-element vector, [*x*, *y*], representing the lower-left location of the visible portion of the window (relative to its virtual canvas).

Version History

6.1	Introduced
-----	------------

IDLgrWindow::GetFontnames

The `IDLgrWindow::GetFontnames` function method returns the list of available fonts that can be used in `IDLgrFont` objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see [Appendix H, “Fonts”](#) for more information.

Syntax

```
Result = Obj->[IDLgrWindow::]GetFontnames(FamilyName [, IDL_FONTS={0 | 1 | 2}] [, STYLES=string] )
```

Return Value

Returns the list of available fonts that can be used in `IDLgrFont` objects.

Arguments

FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as “Helvetica”. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use “*”.

Keywords

IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set `IDL_FONT` to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set `STYLES` to a fully specified style string, such as “Bold Italic”. If you set `STYLES` to the null string, ‘’, only fontnames without style modifiers will be returned. You can use both “*” and “?” as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

Version History

5.0	Introduced
-----	------------

IDLgrWindow::GetProperty

The IDLgrWindow::GetProperty procedure method retrieves the value of a property or group of properties for the window.

Syntax

Obj->[IDLgrWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “IDLgrWindow Properties” on page 4586 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

Version History

5.0	Introduced
-----	------------

IDLgrWindow::GetTextDimensions

The `IDLgrWindow::GetTextDimensions` function method retrieves the dimensions of a text or axis object that will be rendered in a window. In order to compute the effective text dimensions, the object must be inserted into an object graphics hierarchy prior to using this method. The result is a 3-element double-precision floating-point vector [$xDim$, $yDim$, $zDim$] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

Note

The returned results take into account the setting of the `IDLgrText RECOMPUTE_DIMENSIONS` property.

Syntax

```
Result = Obj->[IDLgrWindow::]GetTextDimensions( TextObj
  [, DESCENT=variable] [, PATH=objref(s)] )
```

Return Value

Returns a 3-element double-precision floating-point vector [$xDim$, $yDim$, $zDim$] representing the dimensions of the text or axis object, measured in data units.

Arguments

TextObj

The object reference to a text or axis object for which the text dimensions are requested.

Keywords

DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the `IDLgrText` object). The values are the distance to travel (parallel to the `UPDIR` direction) from the baseline to reach the bottom of all the descenders for the string; the values will be negative or 0. This keyword is only valid if `TextObj` is of the class `IDLgrText`.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If `IDLgrWindow::GetTextDimensions` is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in `IDLgrModel::Add`.

Version History

5.0	Introduced
-----	------------

IDLgrWindow::Iconify

The IDLgrWindow::Iconify procedure method iconifies or de-iconifies the window.

Note

Iconification under window systems is solely handled by the window manager; client applications, such as IDL, do not have the capability to manage icons. The Iconify method provides a hint to the window manager, which applies the information as it sees fit.

Syntax

Obj->[IDLgrWindow::]Iconify, *IconFlag*

Arguments

IconFlag

Set *IconFlag* to 1 (one) to iconify the window or to 0 (zero) to restore the window. If the window is already restored, it is brought to the front of the window stack.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrWindow::Init

The IDLgrWindow::Init function method initializes the window object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Warning

When an IDLgrWindow object is created, its pixel values and depth buffer values are in an indeterminate state. This normally does not create a problem because most windows are completely covered by a non-transparent IDLgrView object, which causes the entire window to be painted with the view's background color and causes the depth buffer to be cleared before drawing the graphics.

However, if any area of the window is left uncovered by an IDLgrView, that area may contain random pixels after the window is drawn. In addition, if a transparent view covers an area of the window not also covered by a non-transparent view, there may be unwanted random pixels in the transparent view as well as random depth buffer values, which may cause some graphic primitives to not appear in the view at all.

Calling the [IDLgrWindow::Erase](#) method is useful for initializing the areas of a window not covered by a view (or which are “under” transparent views) to the desired color and for initializing the depth buffer for subsequent drawing in transparent views.

Syntax

Obj = OBJ_NEW('IDLgrWindow' [, *PROPERTY=value*])

or

Result = *Obj*->[IDLgrWindow::]Init([, *PROPERTY=value*]) *(In a lifecycle method only.)*

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLgrWindow Properties](#)” on page 4586 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

6.3	Introduced
-----	------------

IDLgrWindow::OnExpose

The `IDLgrWindow::OnExpose` procedure method handles notification from the window that an expose event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the `OnExpose` method will automatically redraw the graphics hierarchy specified by the `GRAPHICS_TREE` property. If you are using a subclass of `IDLgrWindow` and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see “[Exporting Drawable Objects](#)” (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[`IDLgrWindow::`]OnExpose, *X*, *Y*, *Width*, *Height*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Width

A floating-point value representing the width of the newly exposed portion of the canvas (in device coordinates).

Height

A floating-point value representing the height of the newly exposed portion of the canvas (in device coordinates).

Keywords

None

IDLgrWindow::OnKeyboard

The `IDLgrWindow::OnKeyboard` procedure method handles notification from the window that a keyboard event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLgrWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[`IDLgrWindow::`]OnKeyboard, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*, *Press*,
Release, *Modifiers*

Arguments

IsASCII

A scalar byte value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to a byte value corresponding to the character of the pressed key. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to a byte value corresponding to the ASCII character of the key that was pressed. Otherwise, this argument is set to zero.

KeySymbol

If *IsASCII* is zero, this argument is set to a long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

X,Y

Long integers containing the *x*-coordinate and *y*-coordinate of the mouse cursor (in device coordinates) at the time of the event.

Press

A long integer indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

Release

A long integer indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

IDLgrWindow::OnMouseDown

The `IDLgrWindow::OnMouseDown` procedure method handles notification from the window that a mouse-down event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLgrWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[`IDLgrWindow::`]OnMouseDown, *X*, *Y*, *ButtonMask*, *Modifiers*, *NumClicks*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 31-17: Bitmask for Button Events

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-18: Bits of the Modifier Key Mask

NumClicks

An integer indicating the number of times the mouse button was clicked.

Keywords

IDLgrWindow::OnMouseMotion

The `IDLgrWindow::OnMouseMotion` procedure method handles notification from the window that a mouse-motion event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLgrWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[`IDLgrWindow::`]OnMouseMotion, *X*, *Y*, *Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

IDLgrWindow::OnMouseUp

The IDLgrWindow::OnMouseUp procedure method handles notification from the window that a mouse-up event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLgrWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLgrWindow::]OnMouseUp, *X*, *Y*, *ButtonMask*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was released:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 31-20: Bitmask for Button Events

Keywords

IDLgrWindow::OnResize

The IDLgrWindow::OnResize procedure method handles notification from the window that a resize event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the OnResize method will automatically resize the window. If you are using a subclass of IDLgrWindow and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLgrWindow::]OnResize, *Width*, *Height*

Arguments

Width

A floating-point value representing the new width of the canvas (in device coordinates).

Height

A floating-point value representing the new height of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLgrWindow::OnWheel

The `IDLgrWindow::OnWheel` procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLgrWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[`IDLgrWindow::`]OnWheel, *X, Y, Delta, Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel generates positive values, pulling the wheel generates negative values. The magnitude of the value depends on the device setting for the individual mouse, but is usually limited to small integer values such as +1, -1, +2, -2, etc.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 31-21: Modifier Values

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLgrWindow::PickData

The IDLgrWindow::PickData function method maps a point in the two-dimensional device space of the window to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the window's device space "hits" a graphic object, or zero if no object was "hit". PickData returns -1 if the point selected falls outside of the specified view or window.

Warning

If you use the DEPTH_WRITE_DISABLE or DEPTH_TEST_DISABLE property of an object to prevent an object from modifying the depth buffer as it is drawn, this also prevents the object from affecting the result returned by the PickData method. The PickData method relies on the contents of the depth buffer at the time it is called to compute and return its results. Be sure that the depth buffer contents are appropriate for getting the expected results from PickData.

Syntax

```
Result = Obj->[IDLgrWindow::]PickData( View, Object, Location, XYZLocation
    [, DIMENSIONS=[w,h]] [, PATH=objref(s)] [, PICK_STATUS=variable])
```

Return Value

Returns 1 if the specified location in the window's device space "hits" a graphic object, or 0 if no object was hit. Returns -1 if the point selected falls outside the specified view or window.

Arguments

View

The object reference of an IDLgrView object that contains the object being picked.

Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

Note

Even though you can specify any object for this argument, the location that is returned may not lie on this object. If another object is in front of the specified object then the returned location lies on the object in front. However, the coordinate system used is that of the object specified by this argument.

Location

A two-element vector $[x, y]$ specifying the location in the window's device space of the point to pick data from.

XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

Note

If the atomic graphic object specified as the target has been transformed using either the `LOCATION` or `DIMENSIONS` properties (this is only possible with `IDLgrAxis`, `IDLgrImage`, and `IDLgrText` objects), these transformations will *not* be included in the data coordinates returned by the `PickData` function. This means that you may need to re-apply the transformation accomplished by specifying `LOCATION` or `DIMENSIONS` once you have retrieved the data coordinates with `PickData`. This situation does not occur if you transform the axis, text, or image object using the `[XYZ]COORD_CONV` properties.

Keywords**DIMENSIONS**

Set this keyword to a two-element array $[w, h]$ to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates $[x, y]$ specified in the *Location* argument, and will occupy the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions $[3, w, h]$.

PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

Value	Description
-1	The pixel falls outside of the window’s viewport.
0	No graphic object is “hit” at that pixel location.
1	A graphic object is “hit” at that pixel location.

Table 31-22: PICK_STATUS Keyword Values

Version History

5.0	Introduced
5.6	Added PICK_STATUS keyword

IDLgrWindow::QueryRequiredTiles

The IDLgrWindow::QueryRequiredTiles function method is used in conjunction with an IDLgrImage object that supports tiling. Initially, this type of IDLgrImage object contains no data. Call this method to determine what data to load into this destination object based on which tiles are visible in a view. Pass the results to [IDLgrImage::SetTileData](#) to load the required portion of the tiled image. When the Draw method is called, the destination object contains the image tiles that are the results of this method's query.

This method returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required. The application can check that COUNT is greater than 0 before accessing the returned array.

Note

If the device is in Color Index mode (COLOR_MODEL=1) or the image has [RENDER_METHOD=1](#) set, then IDL will generate an error as tiling is not supported under these circumstances.

Syntax

```
Result = Obj->[IDLgrWindow::]QueryRequiredTiles( View, Image
  [, ALL_VISIBLE=value] [, COUNT=variable] [, PATH=objref(s)])
```

Return Value

Returns an array of named structures containing information about the tiles that are required, or a scalar integer with the value 0 if no tiles are required.

Each structure in the array describes one required tile and has the following fields:

Field	Data Type	Description
X	Long	The horizontal position of the left side of the tile measured from the left of the image in pixels.
Y	Long	The vertical position of the bottom of the tile measured from the bottom of the image in pixels.
WIDTH	Long	The width of the tile in pixels.

Table 31-23: IDLIMAGETILE Structure

Field	Data Type	Description
HEIGHT	Long	The height of the tile in pixels.
LEVEL	Long	The data resolution, where 0 is the full resolution image. A value of n ($n > 0$) indicates that the resolution is half that of the $n-1$ level.
DEST	OBJREF	The object reference to the destination object that was used to query for the required tiles.

Table 31-23: IDLIMAGETILE Structure (Continued)

The X, Y, WIDTH and HEIGHT elements are all relative to the specified LEVEL. For example, say a large image (level 0) has dimensions of 10000 by 10000 pixels. The tile structure [2048, 2048, 1024, 1024, 0] specifies a 1024 by 1024 pixel area where the lower-left corner of the tile is (2048, 2048) pixels from the lower-left corner of the original, level 0 image. This is shown in the left portion of the following figure.

When you zoom out to 50% of the original resolution, you can load the level 1 image (5000 by 5000 pixels), a subsampled version of the large image. Here, the tile [1024, 1024, 1024, 1024, 1] specifies a 1024 by 1024 pixel area of the image with the lower-left corner being (1024, 1024) from the lower-left corner of the image. Both of these tiles have their lower-left corner at the same physical location of the image, but the second tile covers four times the area as it is a lower resolution version of the data.

Figure 31-11: Interaction Between Image Level and Zoom with Equal Tile Sizes

Note

See “[Image Tiling](#)” (Chapter 4, *Object Programming*) for more information on creating an image pyramid and for tiling examples.

Arguments

View

An object reference to the IDLgrView object used to render the image object. This is required so the visible tiles can be determined.

Image

An object reference to the tiled IDLgrImage object that will be tested to determine which of its tiles are required.

Keywords

ALL_VISIBLE

Set this keyword if QueryRequiredTiles should return all tiles that are visible even if they already have tile data loaded at the required level.

COUNT

Set this keyword equal to a named variable that, on return, contains the number of tiles that are required.

PATH

Set this keyword equal to a vector of object references that uniquely defines the path through the graphics hierarchy used to compute which tiles are visible. Each object specified must contain an alias; tile visibility is computed for the version of the image object (specified by *Image*) that lies at the end of the specified path.

Specifying a unique path through the graphics hierarchy may require multiple objects if multiple aliases are used. If multiple objects are required to define the value of PATH, the objects must be specified in the order they appear in the path, beginning with the object that is closest to the root of the hierarchy.

If this keyword is not set, the path from *Image* to the top of the graphics hierarchy is determined by the PARENT properties of the objects in the hierarchy. In this case, no alias paths are followed.

Note

For more information on aliases, refer to the [ALIAS](#) keyword in IDLgrModel::Add.

Version History

6.2	Introduced
7.0	Added PATH keyword to QueryRequiredTiles to handle aliases.

IDLgrWindow::Read

The IDLgrWindow::Read function method reads an image from a window. The returned value is an instance of the [IDLgrImage](#) object class.

Syntax

```
Result = Obj->[IDLgrWindow:]Read()
```

Arguments

None

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrWindow::Select

The `IDLgrWindow::Select` function method returns a list of objects selected at a specified location. If no objects are selected, the `Select` function returns -1.

Note

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

Syntax

```
Result = Obj->[IDLgrWindow::]Select( Picture, XY [, DIMENSIONS=[width,
    height]] [, /ORDER] [, SUB_SELECTION=variable] [, UNITS={0 | 1 | 2 | 3} ] )
```

Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

Arguments

Picture

The view or scene (an instance of the `IDLgrView`, `IDLgrViewgroup`, or `IDLgrScene` class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their `SELECT_TARGET` property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The `ORDER` keyword can be used to change this behavior.)

XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels, as defined by the `DIMENSIONS` keyword.

Keywords

DIMENSIONS

Set this keyword to a two-element array $[w, h]$ to specify that the selection box will have a width w and a height h , and will be centered about the coordinates $[x, y]$ specified in the XY argument. The box occupies the rectangle defined by:

$$(x - (w/2), y - (h/2)) - (x + (w/2), y + (h/2))$$

Any object that intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If $ORDER=0$ (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If $ORDER=1$, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

Tip

If you are using $DEPTH_TEST_FUNCTION=4$ (“less than or equal”) on your graphics objects, set $ORDER=1$ to return objects at the same depth in the order in which they appear visually.

SUB_SELECTION

Set this keyword to a named variable that upon return will contain a vector of references to the graphic objects that were sub-selected at the given location. This vector includes: all graphic objects that are:

- Graphic objects contained by the nearest selected object (the first object in the return value)
- Select targets (IDLgrModel objects with the $SELECT_TARGET$ property set)
- Graphic objects displayed at the given XY location

UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination

Version History

5.0	Introduced
6.0	Added ORDER keyword
6.1	Added SUB_SELECTION keyword

IDLgrWindow::SetCurrentCursor

The IDLgrWindow::SetCurrentCursor procedure method sets the current cursor image to be used while positioned over a drawing area.

Syntax

Obj->[IDLgrWindow::]SetCurrentCursor [, *CursorName*] [, **IMAGE**=16 x 16 *bitmap*] [, **MASK**=16 x 16 *bitmap*] [, **HOTSPOT**=[*x*, *y*]]

Unix-Only Keywords: [, **STANDARD**=*index*]

Arguments

CursorName

A string that specifies which built-in cursor to use. This argument is ignored if any keywords to this routine are set. This string can either be a name provided to the REGISTER_CURSOR routine or one of the following:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

Keywords

IMAGE

Set this keyword to a 16x16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. This image can be created from a string array using the **CREATE_CURSOR** procedure. The offset from the upper-left pixel to the point that is considered the “hot spot” can be provided via the **HOTSPOT** keyword.

MASK

When the IMAGE keyword is set, the MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are “masked out”.

HOTSPOT

Set this keyword to a two-element vector specifying the $[x, y]$ pixel offset of the cursor “hot spot”, the point which is considered to be the mouse position, from the upper left corner of the cursor image. This parameter is only applicable if IMAGE is provided. The cursor image is displayed top-down (the first row is displayed at the top).

STANDARD

This keyword is only available on UNIX platforms.

Set this keyword to an X11 cursor font index to change the appearance of the cursor in the IDL graphics window to a glyph in this font. On non-X platforms, setting this keyword displays the crosshair cursor.

Version History

5.0	Introduced
5.6	Added <i>CursorName</i> argument

See Also

[REGISTER_CURSOR](#), [CREATE_CURSOR](#)

IDLgrWindow::SetCurrentZoom

The IDLgrWindow::SetCurrentZoom procedure method does the following:

- Sets the `CURRENT_ZOOM` property.
- Sets the `ZOOM_NSTEP` property to the closest integer multiple of `ZOOM_BASE` that results in the specified zoom factor.

Note

This method does not change the window contents automatically. The application is responsible for updating the window content based on the new zoom value.

Syntax

Obj-> [IDLgrWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

Arguments

ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 zoom out; values greater than 1.0 zoom in on the contents of the window.

Keywords

RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

Version History

6.1	Introduced
-----	------------

IDLgrWindow::SetProperty

The IDLgrWindow::SetProperty procedure method sets the value of a property or group of properties for the window.

Syntax

Obj->[IDLgrWindow::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLgrWindow Properties](#)” on page 4586 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

IDLgrWindow::Show

The IDLgrWindow::Show procedure method exposes or hides a window.

Syntax

Obj->[IDLgrWindow::]Show, *Position*

Arguments

Position

Set this argument equal to a non-zero value to expose the window, or to 0 to hide the window.

Keywords

None

Version History

5.0	Introduced
-----	------------

IDLgrWindow::ZoomIn

The IDLgrWindow::ZoomIn procedure method does the following:

- Increments the value of the `ZOOM_NSTEP` property.
- Updates the value of the `CURRENT_ZOOM` property to reflect the product of the `ZOOM_BASE` and `ZOOM_NSTEP` properties.

Note

This method does not change the window contents automatically. The application is responsible for updating the window content based on the new zoom value.

Syntax

Obj->[IDLgrWindow::]ZoomIn

Arguments

None

Keywords

None

Example

While you are free to use the value of the `CURRENT_ZOOM`, `ZOOM_BASE`, and `ZOOM_NSTEP` properties to modify the contents of the IDLgrWindow in any way you see fit, one choice is to modify the value of the `VIEWPLANE_RECT` property of the IDLgrView object that contains your graphics.

First, we create an IDLgrWindow containing a simple plot:

```
mywindow = OBJ_NEW('IDLgrWindow', RETAIN=2)
myview = OBJ_NEW('IDLgrView', VIEWPLANE_RECT=[-10,-10,20,20])
mymodel = OBJ_NEW('IDLgrModel')

x = (FINDGEN(21) / 10.0 - 1.0) * 10.0
y = RANDOMU(seed, 21) * 10.0 - 5.0
myplot1 = OBJ_NEW('IDLgrPlot', x, y)

myview->Add, mymodel
```

```
mymodel->Add, myplot1
mywindow->Draw, myview
```

Next, we use the `ZoomIn` method to change the current zoom, and then change the `VIEWPLANE_RECT` property by the current zoom amount:

```
mywindow->ZoomIn
mywindow->GetProperty, CURRENT_ZOOM=cz
myview->GetProperty, VIEWPLANE_RECT=vr
myview->SetProperty, VIEWPLANE_RECT=vr*cz
mywindow->Draw, myview
```

(Another option would be to use the `IDLgrModel::Scale` method to modify the scale factors used by the model object.)

When you have finished with the example, destroy the `IDLgrWindow` and `IDLgrView` objects:

```
OBJ_DESTROY, mywindow
OBJ_DESTROY, myview
```

Version History

6.1	Introduced
-----	------------

IDLgrWindow::ZoomOut

The IDLgrWindow::ZoomOut procedure method does the following:

- Decrements the value of the `ZOOM_NSTEP` property.
- Updates the value of the `CURRENT_ZOOM` property to reflect the product of the `ZOOM_BASE` and `ZOOM_NSTEP` properties.

Note

This method does not change the window contents automatically. The application is responsible for updating the window content based on the new zoom value.

Syntax

Obj->[IDLgrWindow::]ZoomOut

Arguments

None

Keywords

None

Example

See “IDLgrWindow::ZoomIn” on page 4651.

Version History

6.1	Introduced
-----	------------

Chapter 32

iTools Object Classes

This chapter describes IDL's built-in iTool object classes.

IDLitCommand	4656	IDLitManipulatorVisual	4876
IDLitCommandSet	4669	IDLitOperation	4885
IDLitComponent	4675	IDLitParameter	4907
IDLitContainer	4706	IDLitParameterSet	4930
IDLitData	4720	IDLitReader	4946
IDLitDataContainer	4742	IDLitTool	4959
IDLitDataOperation	4755	IDLitToolbase	5026
IDLitDirectWindow	4770	IDLitUI	5028
IDLitIMessaging	4794	IDLitVisualization	5049
IDLitManipulator	4813	IDLitWindow	5118
IDLitManipulatorContainer	4846	IDLitWriter	5167
IDLitManipulatorManager	4867		

IDLitCommand

The IDLitCommand class provides a dynamic data dictionary storage system. Its methods and properties allow the iTool developer to store information about the execution of an iTool operation on a single target object. It provides a tag-based mechanism for storing and retrieving this information, which allows the iTool developer to easily implement undo and redo functionality for an operation.

This class is written in the IDL language. Its source code can be found in the file `idlitcommand__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitCommand::Init](#)” on page 4666.

Properties

Objects of this class have the following properties. See “[IDLitCommand Properties](#)” on page 4658 for details on individual properties.

- [SKIP_REDO](#)
- [SKIP_UNDO](#)
- [TARGET_IDENTIFIER](#)
- [OPERATION_IDENTIFIER](#)

In addition, objects of this class inherit the properties of the superclass of this class.

Methods

This class has the following methods:

- [IDLitCommand::AddItem](#)

- [IDLitCommand::Cleanup](#)
- [IDLitCommand::GetItem](#)
- [IDLitCommand::GetProperty](#)
- [IDLitCommand::GetSize](#)
- [IDLitCommand::Init](#)
- [IDLitCommand::SetProperty](#)

In addition, this class inherits the methods of its superclass.

Examples

See [“Creating a New Generalized Operation”](#) (Chapter 7, *iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Added SKIP_REDO, SKIP_UNDO properties

IDLitCommand Properties

IDLitCommand objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via `IDLitCommand::GetProperty`. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLitCommand::Init`. Properties with the word “Yes” in the “Set” column in the property table can be set via `IDLitCommand::SetProperty`.

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- `SKIP_REDO`
- `SKIP_UNDO`
- `TARGET_IDENTIFIER`
- `OPERATION_IDENTIFIER`

In addition, objects of this class inherit:

- `IDLitComponent`

SKIP_REDO

A Boolean value that determines whether the command object will be skipped when performing a Redo operation on the command set that contains this command. If this property is set to True (1), the command object will be skipped. The default is False (0), which includes this command during the Redo operation.

The SKIP_REDO property is useful when you have a command that needs to be Undone, but not Redone.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SKIP_UNDO

A Boolean value that determines whether the command object will be skipped when performing an Undo operation on the command set that contains this command. If this property is set to True (1), the command object will be skipped. The default is False (0), which includes this command during the Undo operation.

The SKIP_UNDO property is useful when you have a command that needs to be Redone, but not Undone.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TARGET_IDENTIFIER

The iTool identifier of the *target* object for this command. This is the item on which the operation associated with the command will execute.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPERATION_IDENTIFIER

The iTool identifier for the *operation* associated with this command. When an undo-redo operation takes place, the command object is passed to this operation.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitCommand::AddItem

The IDLitCommand::AddItem function method adds the specified data item to the data dictionary associated with this object.

Note

If a data item with the specified identifying string is already in the data dictionary, the new value is not added unless the OVERWRITE keyword is set, in which case the old value is discarded.

Syntax

```
Result = Obj->[IDLitCommand::]AddItem(StrItem, Item[, /OVERWRITE])
```

Return Value

Returns 1 if the item was successfully added to the data dictionary, or 0 if the new value was not added.

Arguments

StrItem

A scalar string used to identify the data specified by the *Item* argument in the data dictionary. This string is treated in a case-insensitive manner.

Item

A data item of any IDL data type.

Keywords

OVERWRITE

Normally, if an item already exists in the data dictionary of an IDLitCommand object, it is not overwritten. If this keyword is set, the original value will be overwritten.

Note

If the item being replaced uses dynamic memory (that is, if it is a pointer or object reference), the memory must be released by calling PTR_FREE or OBJ_DESTROY before overwriting the value.

Version History

6.0	Introduced
-----	------------

IDLitCommand::Cleanup

The IDLitCommand::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitCommand::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitCommand::GetItem

The IDLitCommand::GetItem function method retrieves the specified item from the data dictionary associated with this object.

Syntax

Result = *Obj*->[IDLitCommand::]GetItem(*StrItem*, *Item*)

Return Value

Returns 1 if the *Item* is retrieved successfully, or 0 if *Item* is not found in the data dictionary.

Arguments

StrItem

A scalar string used to identify the data to be retrieved from the data dictionary. This string is treated in a case-insensitive manner.

Item

A named IDL variable that will contain the IDLitData object retrieved from the data dictionary.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitCommand::GetProperty

The IDLitCommand::GetProperty procedure method retrieves the value of a property or group of properties of a command object.

Syntax

Obj->[IDLitCommand::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 4658 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

Version History

6.0	Introduced
-----	------------

IDLitCommand::GetSize

The IDLitCommand::GetSize function method returns an approximate value for the amount of memory being used by the items in the data dictionary associated with this object.

Syntax

Result = *Obj*->[IDLitCommand::]GetSize([, /KILOBYTES])

Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

Arguments

None

Keywords

KILOBYTES

Set this keyword to return the number of kilobytes of memory being used by the data dictionary. By default, this function returns the number of bytes of memory being used.

Version History

6.0	Introduced
-----	------------

IDLitCommand::Init

The IDLitCommand::Init function method initializes the object and allows specification of items associated with it.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitCommand' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitCommand::]Init( [, PROPERTY=value] ) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 4658 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object ([IDLitComponent](#)).

Version History

6.0	Introduced
-----	------------

IDLitCommand:: SetProperty

The IDLitCommand::SetProperty procedure method sets the value of a property or group of properties for the command object.

Syntax

Obj->[IDLitCommand::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitCommand Properties](#)” on page 4658 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitCommandSet

The IDLitCommandSet class stores a collection of IDLitCommand objects, allowing a group of commands to be managed as a single item. Command sets are useful as containers for IDLitCommand objects generated by the application of an iTool operation to multiple target items; the generated command set objects are used to provide undo/redo functionality to the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitcommandset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDL_Container](#)

[IDLitCommand](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitCommandSet::Init](#)” on page 4674.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitCommandSet::Cleanup](#)
- [IDLitCommandSet::GetSize](#)
- [IDLitCommandSet::Init](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [“Creating a New Generalized Operation”](#) (Chapter 7, *iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
-----	------------

IDLitCommandSet Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDL_Container](#)
- [IDLitCommand](#)

IDLitCommandSet::Cleanup

The IDLitCommandSet::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, Obj

or

Obj->[IDLitCommandSet::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitCommandSet::GetSize

The `IDLitCommandSet::GetSize` function method returns an approximate value for the amount of memory being used by the items contained by this command set. When called, the method will call the `GetSize` method on all of the command objects that it contains and generate a sum of the values.

Syntax

Result = *Obj*->[IDLitCommand::]GetSize([/KILOBYTES])

Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

Arguments

None

Keywords

KILOBYTES

Set this keyword to return the number of kilobytes of memory being used. By default, this function returns the number of bytes of memory being used.

Version History

6.0	Introduced
-----	------------

IDLitCommandSet::Init

The IDLitCommandSet::Init function method initializes the object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitCommandSet')
```

or

```
Result = Obj->[IDLitCommandSet::]Init() (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

All keywords are passed to the superclass of this object ([IDLitCommand](#)).

Version History

6.0	Introduced
-----	------------

IDLitComponent

The IDLitComponent class is the base component from which all iTool components should subclass. The IDLitComponent class provides support for property descriptors and property registration, and defines properties that are common to all iTool component objects.

Note

This class is now a superclass of all the atomic graphical (IDLgr*) object classes.

Superclasses

None

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitComponent::Init”](#) on page 4690.

Properties

Objects of this class have the following properties. See [“IDLitComponent Properties”](#) on page 4677 for details on individual properties.

- [COMPONENT_VERSION](#)
- [DESCRIPTION](#)
- [HELP](#)
- [ICON](#)
- [IDENTIFIER](#)
- [NAME](#)
- [PRIVATE](#)
- [UVALUE](#)

Methods

This class has the following methods:

- [IDLitComponent::Cleanup](#)
- [IDLitComponent::EditUserDefProperty](#)
- [IDLitComponent::GetFullIdentifier](#)
- [IDLitComponent::GetProperty](#)
- [IDLitComponent::GetPropertyAttribute](#)
- [IDLitComponent::GetPropertyByIdentifier](#)
- [IDLitComponent::Init](#)
- [IDLitComponent::NotifyBridge](#)
- [IDLitComponent::QueryProperty](#)
- [IDLitComponent::RegisterProperty](#)
- [IDLitComponent::Restore](#)
- [IDLitComponent::SetProperty](#)
- [IDLitComponent::SetPropertyAttribute](#)
- [IDLitComponent::SetPropertyByIdentifier](#)
- [IDLitComponent::UpdateComponentVersion](#)

Version History

6.0	Introduced
6.1	Added COMPONENT_VERSION property
6.3	Added IDLitComponent::NotifyBridge

IDLitComponent Properties

IDLitComponent objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitComponent::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitComponent::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitComponent::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [COMPONENT_VERSION](#)
- [DESCRIPTION](#)
- [HELP](#)
- [ICON](#)
- [IDENTIFIER](#)
- [NAME](#)
- [PRIVATE](#)
- [UVALUE](#)

COMPONENT_VERSION

A integer value representing the version of the component object. This value is set automatically and is intended to aid in determining how a component object should be restored by the Restore method.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

DESCRIPTION

A string giving the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

HELP

A scalar string representing the help topic associated with this object. If this property is not set, or is set to a null string, then the object class name will be used as the default help topic.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ICON

A string specifying the name of an icon to be associated with this object. Typically, this property is the name of a bitmap file used when displaying this object in a tree view. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for details.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDENTIFIER

A string containing the *object identifier* for this object. If this property is not specified, then the NAME property is used as the identifier. See “[iTool Object](#)

Identifiers” (Chapter 2, *iTool Developer’s Guide*) for details about how identifiers are named.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string giving the human-readable name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

PRIVATE

A boolean value that indicates whether the object should be marked as private. Objects marked private (and all of their children) are not displayed in the graphical iTool browser windows.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

UVALUE

A value of any type containing any information you wish.

Note

Object references or pointers contained in the UVALUE property are *not* automatically cleaned up when the IDLitComponent object is destroyed.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitComponent::Cleanup

The IDLitComponent::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitComponent:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitComponent::EditUserDefProperty

The IDLitComponent::EditUserDefProperty function method defines the interface that is displayed when a user selects the “Edit” button on a user-defined property in the property sheet interface. Typically, this method will display an interactive dialog that allows the user to change the value of the property.

Note

An iTool object class that includes a user-defined property *must* implement this method if the property is displayed in a property sheet — that is, if the property is registered and not hidden. If an iTool object class has no user-defined properties that are displayed in a property sheet, there is no need to supply an EditUserDefProperty method.

See “[User Defined Property Types](#)” (Chapter 4, *iTool Developer’s Guide*) for a discussion of how the property sheet interface displays user-defined properties.

Syntax

Result = *Obj*->[IDLitComponent::]EditUserDefProperty(*iTool*, *PropertyIdentifier*)

Return Value

Returns a 1 if the property value was changed, or a 0 if the property value was not changed.

Note

If the return value is 1, the property sheet interface automatically updates the displayed property value using the value of the property’s USERDEF attribute. If the return value is 0, no update takes place.

Arguments

iTool

An object reference to the current iTool object.

PropertyIdentifier

A string containing the property identifier of the user-defined property.

Tip

Since there can only be one `EditUserDefProperty` method for each class, you can use the *PropertyIdentifier* argument to determine which user-defined property is being edited.

Keywords

None

Example

The following is the `EditUserDefProperty` method of the `IDLitOpConvolution` operation class. Selecting and editing the `Kernel` property of this operation displays a dialog that allows the user to edit a convolution kernel.

```
FUNCTION IDLitOpConvolution::EditUserDefProperty, oTool, $
    identifier

CASE identifier OF

    'KERNEL': RETURN, oTool->DoUIService('ConvolKernel', self)

ELSE:

ENDCASE

RETURN, 0

END
```

This method simply checks the property identifier to determine whether it matches the string `'KERNEL'`. If it does, it returns the value returned by the `DoUIService` method; otherwise it returns zero. In this case, the `DoUIService` method actually handles the modification of the property value. See [“User Defined Property Types”](#) (Chapter 4, *iTool Developer’s Guide*) for additional discussion.

Version History

6.0	Introduced
-----	------------

IDLitComponent::GetFullIdentifier

The `IDLitComponent::GetFullIdentifier` function method navigates the iTool object container hierarchy of the object on which it is called and retrieves the fully-qualified object identifier. The full identifier is constructed by recursively retrieving the parent object reference and prepending this to the identifier, separated by `/` characters. The parent must inherit from the `IDLitContainer` class. The full identifier string has the following form:

```
/. . . /GRANDPARENTID/PARENTID/OBJID
```

If the *Objref* argument is specified, the function returns the object identifier path relative to the specified object.

See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for additional discussion of object identifiers.

Syntax

```
Result = Obj->[IDLitComponent::]GetFullIdentifier([Objref])
```

Return Value

Returns a string containing the object identifier.

Note

The full object identifier of a top-level *container* object is “/” even if the top-level container’s `IDENTIFIER` property is set to some other value. If the top-level object is *not* a container object, the full object identifier is a null string (“”) even if the top-level object’s `IDENTIFIER` property is set to some other value.

Arguments

Objref

An object reference to an iTool component object. If this argument is specified, the returned value is a relative object identifier, beginning with *Objref*. If this argument is not specified, the returned value is a fully-qualified object identifier.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitComponent::GetProperty

The IDLitComponent::GetProperty procedure method retrieves the value of an IDLitComponent property or properties.

Syntax

Obj->[IDLitComponent::]GetProperty[, *PROPERTY=variable*] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under “[IDLitComponent Properties](#)” on page 4677 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

NO_COPY

Note

This keyword only has an effect when getting the UVALUE property.

Usually, when getting the UVALUE property, IDL makes a copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles the GetProperty operation differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used to obtain the information from the UVALUE property without the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined; in a call to the GetProperty method, this means that the UVALUE property of the IDLitComponent object becomes undefined.

Version History

6.0	Introduced
6.4	Added NO_COPY keyword

IDLitComponent::GetPropertyAttribute

The IDLitComponent::GetPropertyAttribute procedure method retrieves property attribute values for a registered property.

Syntax

```
Obj->[IDLitComponent::]GetPropertyAttribute, PropertyIdentifier  
[, TYPE=variable]
```

Arguments

PropertyIdentifier

A string containing the property identifier of the registered property.

Keywords

Any keywords to the RegisterProperty method followed by the word “Get” can be retrieved. In addition, the following keyword is available:

TYPE

Set this argument to a named variable that returns the TYPE code as an integer, as specified under the *Type* argument to [IDLitComponent::RegisterProperty](#).

Version History

6.0	Introduced
-----	------------

IDLitComponent::GetPropertyByIdentifier

The IDLitComponent::GetPropertyByIdentifier function method retrieves the value of an IDLitComponent property.

Tip

The IDLitComponent::GetPropertyByIdentifier method is similar to the IDLitComponent::GetProperty method, but is useful for cases where the *property identifier* is defined at runtime.

Syntax

```
Result = Obj->[IDLitComponent::]GetPropertyByIdentifier(PropertyIdentifier,  
Value)
```

Return Value

Returns 1 if the property value is defined, or 0 if the property value is undefined.

Arguments

PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the GetProperty method of the component.

Value

A named variable that will contain the value of the property. If the property value is currently undefined, then the contents of the variable specified by *Value* will not be modified.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitComponent::Init

The IDLitComponent::Init function method initializes the IDLitComponent object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitComponent'[, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitComponent::]Init([, PROPERTY=value]) (In a lifecycle  
method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitComponent Properties](#)” on page 4677 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitComponent::NotifyBridge

The IDLitComponent::NotifyBridge procedure method is used to broadcast a notification message to the Export Bridge object that is wrapping the IDLitComponent object. If this method is called on an object that is not connected to the Export Bridge, the method quietly returns.

For more information on the Export Bridge, see [“Exporting from IDL” \(IDL Connectivity Bridges\)](#).

Syntax

Obj->IDLitComponent::NotifyBridge, IdMessage, Value

Arguments

IdMessage

A scalar string that will uniquely identify the message being sent.

Value

A scalar string that is associated with the message being sent.

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitComponent::QueryProperty

The IDLitComponent::QueryProperty function method checks whether a property identifier is registered, or retrieves a list of all registered properties.

Syntax

Result = *Obj*->[IDLitComponent::]QueryProperty([*PropertyIdentifier*])

Return Value

Returns a 1 if *PropertyIdentifier* is a scalar string that corresponds to a valid registered property, or a 0 otherwise. If *PropertyIdentifier* is an array, the result is an array of 1s and 0s.

If *PropertyIdentifier* is not specified, *Result* is a string array containing the identifiers of all registered properties.

Arguments

PropertyIdentifier

A scalar string or string array containing property identifiers.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitComponent::RegisterProperty

The IDLitComponent::RegisterProperty procedure method registers a property as belonging to the component. Only registered properties are displayed in the graphical property sheet interface for the object.

Syntax

```
Obj->[IDLitComponent::]RegisterProperty, PropertyIdentifier[, Type]
[, /BOOLEAN] [, /COLOR] [, DESCRIPTION=string]
[, ENUMLIST=stringvector] [, /FLOAT] [, /HIDE] [, /INTEGER]
[, /LINESTYLE] [, NAME=string] [, /SENSITIVE] [, /STRING] [, /SYMBOL]
[, /THICKNESS] [, /UNDEFINED] [, USERDEF=string]
[, VALID_RANGE=vector]
```

Arguments

PropertyIdentifier

A scalar string containing the property identifier. GetProperty and SetProperty methods accept this string as a keyword.

Type

An optional integer argument representing the property type. Values recognized by Property Sheets are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT
- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

If *Type* is not supplied, then one of the type keywords must be set instead.

Note

Properties registered as Type 2 (Integer) can contain integers up to 64-bits.

Keywords

Some of the following keywords correspond to *attributes* of the property being registered. Keywords followed by the word “Get” indicate attributes that can be retrieved by the `IDLitComponent::GetPropertyAttribute` method. Keywords followed by the word “Set” indicate attributes that can be set by the `IDLitComponent::SetPropertyAttribute` method.

Some of the following keywords correspond to iTool property data types, which can also be specified via the *Type* argument. Note that if both the *Type* argument and one of the corresponding keywords are set, the keyword value will be honored.

BOOLEAN

Set this keyword to indicate that the property type is BOOLEAN. Properties of type BOOLEAN must accept an integer value of either 0 (“False”) or 1 (“True”). Setting this keyword is equivalent to setting the TYPE argument equal to 1.

COLOR

Set this keyword to indicate that the property type is COLOR. Properties of type COLOR must accept a three-element integer array containing an RGB triplet. Setting this keyword is equivalent to setting the TYPE argument equal to 5.

DESCRIPTION

(Get, Set)

Set this keyword to a string containing the description of this property.

Note

Do not confuse the DESCRIPTION *property attribute* with the DESCRIPTION *property*. The DESCRIPTION property attribute is *not* displayed in the graphical property sheet interface.

ENUMLIST

(Get, Set)

Set this keyword equal to an array of strings to be displayed in the dropdown menu displayed by a property of type ENUMLIST. The default is a scalar null string.

Properties of type ENUMLIST report their value as an integer between 0 and $n-1$, where n is the number of elements in the enumerated list. Setting this keyword implies that the TYPE argument is equal to 9.

FLOAT

Set this keyword to indicate that the property type is FLOAT. Properties of type FLOAT must accept a scalar double-precision floating-point value. Setting this keyword is equivalent to setting the TYPE argument equal to 3.

HIDE

(Get, Set)

Set this keyword to hide the given property when displaying the graphical property sheet interface. By default, all registered properties are displayed.

INTEGER

Set this keyword to indicate that the property type is INTEGER. Properties of type INTEGER must accept a scalar integer value (up to 64-bit integers). Setting this keyword is equivalent to setting the TYPE argument equal to 2.

LINESTYLE

Set this keyword to indicate that the property type is LINESTYLE. Properties of type LINESTYLE must accept an integer specifying a pre-defined linestyle, as described under the [LINESTYLE](#) property of the [IDLgrPolyline](#) class. Setting this keyword is equivalent to setting the TYPE argument equal to 6.

NAME

(Get, Set)

Set this keyword to a string giving the human-readable name for the property. The NAME string will be used when displaying the graphical property sheet interface. If NAME is not set, the value of the *PropertyIdentifier* argument is used.

Note

Do not confuse the NAME *property attribute* with the NAME *property*.

SENSITIVE

(Get, Set)

Set this keyword to zero to make the given property insensitive in the graphical property sheet interface. By default, registered properties are sensitive.

STRING

Set this keyword to indicate that the property type is `STRING`. Properties of type `STRING` must accept a scalar string of any length. Setting this keyword is equivalent to setting the `TYPE` argument equal to 4.

SYMBOL

Set this keyword to indicate that the property type is `SYMBOL`. Properties of type `SYMBOL` must accept an integer specifying one of the pre-defined symbol types described under `IDLgrSymbol::Init`. Setting this keyword is equivalent to setting the `TYPE` argument equal to 7.

THICKNESS

Set this keyword to indicate that the property type is `THICKNESS`. Properties of type `THICKNESS` must accept an integer between 1 and 10 specifying the line thickness in points. Setting this keyword is equivalent to setting the `TYPE` argument equal to 8.

UNDEFINED

(Get, Set)

Set this keyword to indicate that the property should appear as a blank cell when displayed in the graphical property sheet interface. This is useful in situations where properties of multiple objects are displayed in the property sheet (either because multiple objects are selected, or because the objects have been grouped).

Note

It is the *iTool* developer's responsibility to set this property attribute back to zero. Use the `SET_DEFINED` field of the `WIDGET_PROPERTY SHEET` event structure to determine when to set the `UNDEFINED` attribute back to zero.

USERDEF

(Get, Set)

Set this keyword to a string that represents a user-defined property. Properties of type `USERDEF` can accept and return variables of any type. When the actual property value changes, it is assumed that the string value of the `USERDEF` attribute will also be modified to reflect the new property value. Setting this keyword implies that the `TYPE` argument is equal to 0.

VALID_RANGE

(Get, Set)

For INTEGER or FLOAT types, set this keyword to a two- or three-element vector specifying the [minimum, maximum] or [minimum, maximum, increment] for valid values of the property.

What is displayed for the property sheet number cell depends upon the following:

- If this attribute is not specified — the property sheet displays an editable text field where masked editing is enforced, and the range is that of the data type. The only accepted keystrokes are the ten digits and the plus and minus signs. If the float type is specified, the decimal, and “d” and “e” (scientific exponent notation tokens) are also allowed.
- If a range is specified without an increment — the property sheet displays a spinner control that allows the user to click, or click and hold the up or down buttons to change the value. For an integer type, the increment is one. For a float type, the increment equals approximately 1/100 of the range. For example, a range of 100 results in an increment of 1. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The editable text field (featuring masked editing) also allows the user to enter a numerical value.
- If a range and increment are specified — the property sheet displays a slider with a marker that can be repositioned to change the value. A value is snapped to the nearest allowable value when a value outside the range, or not equal to an incremental value, is entered. The increment value must be positive and will be converted to an integer for INTEGER types. Specifying an increment of 0 (zero) is the same as specifying a range without an increment. The editable text field (featuring masked editing) also allows the user to enter a numerical value.

The following code creates properties containing various number cells:

```
; Number cell with no explicit range.
self->RegisterProperty, 'integer1', /INTEGER, $
    NAME = 'Integer1', description = 'Integer'

; Number cell with spinner control and explicit range.
self->RegisterProperty, 'integer2', /INTEGER, $
    NAME = 'Integer2', VALID_RANGE = [ -100, 100 ]

; Number cell with slider control, explicit range, and
; increment.
self->RegisterProperty, 'float1', /FLOAT, $
    NAME = 'Float1', VALID_RANGE = [ -20.0D, 5.0D, 0.5D ]
```

Version History

6.0	Introduced
6.1	Added spinner control functionality to VALID_RANGE keyword

IDLitComponent::Restore

The `IDLitComponent::Restore` procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

Note

This method is designed to be implemented by a subclass of `IDLitComponent`, to perform any transition work necessary when a component object is restored.

Syntax

Obj->[\[IDLitComponent::\]Restore](#)

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

See Also

[IDLitComponent::UpdateComponentVersion](#), [IDL_Savefile](#), [SAVE](#), [RESTORE](#)

IDLitComponent:: SetProperty

The IDLitComponent::SetProperty procedure method sets the value of an IDLitComponent property or properties.

Syntax

Obj->[IDLitComponent::]SetProperty[, *PROPERTY=value*] [, /NO_COPY]

Arguments

None

Keywords

Any property listed under “IDLitComponent Properties” on page 4677 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

NO_COPY

Note

This keyword only has an effect when setting the UVALUE property.

Usually, when setting the UVALUE property, IDL makes a copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles the SetProperty operation differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used to obtain the information from the UVALUE property without the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined; in a call to the SetProperty method, this means that the variable passed in as UVALUE becomes undefined.

Version History

6.0	Introduced
6.4	Added NO_COPY keyword.

IDLitComponent:: SetPropertyAttribute

The IDLitComponent::SetPropertyAttribute procedure method sets one or more property attributes for a registered property.

Syntax

Obj->[IDLitComponent::](#)SetPropertyAttribute , *PropertyIdentifier*

Arguments

PropertyIdentifier

A string containing the property identifier of the registered property.

Keywords

Any keywords to the [IDLitComponent::RegisterProperty](#) method followed by the word “Set” can be set.

Version History

6.0	Introduced
-----	------------

IDLitComponent:: SetPropertyByIdentifier

The IDLitComponent::SetPropertyByIdentifier procedure method sets the value of an IDLitComponent property.

Tip

The IDLitComponent::SetPropertyByIdentifier method is similar to the IDLitComponent::SetProperty method, but is useful for cases where the *PropertyIdentifier* is defined at runtime, and avoids the overhead of creating an *_EXTRA* structure to pass to SetProperty.

Syntax

Obj->[IDLitComponent::]SetPropertyByIdentifier, *PropertyIdentifier*, *Value*

Arguments

PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the SetProperty method of the component.

Value

The new value for the property.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitComponent::UpdateComponentVersion

The IDLitComponent::UpdateComponentVersion procedure method updates the value of the COMPONENT_VERSION property for the specified object to match the version associated with the current release of IDL. This method is intended for use after calling the Restore method on a component object, so that the object can be identified as having been restored.

Syntax

Obj->[IDLitComponent::](#)UpdateComponentVersion

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

See Also

[IDLitComponent::Restore](#)

IDLitContainer

The IDLitContainer class is a specialization of the IDL_Container class designed to manage collections of IDLitComponent objects and provide methods to work with the iTools *identifier* system. IDLitContainer object methods allow you to add, retrieve, and remove values from a IDLitContainer-based hierarchy using either object references or iTool identifiers.

This class is written in the IDL language. Its source code can be found in the file `idlitcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDL_Container](#)

[IDLitComponent](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitContainer::Init](#)” on page 4717.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitContainer::Add](#)
- [IDLitContainer::AddByIdentifier](#)
- [IDLitContainer::Cleanup](#)
- [IDLitContainer::FindIdentifiers](#)
- [IDLitContainer::Get](#)

- [IDLitContainer::GetByIdentifier](#)
- [IDLitContainer::Init](#)
- [IDLitContainer::Remove](#)
- [IDLitContainer::RemoveByIdentifier](#)

In addition, this class inherits the methods of its superclasses.

Version History

6.0	Introduced
-----	------------

IDLitContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDL_Container](#)
- [IDLitComponent](#)

IDLitContainer::Add

The IDLitContainer::Add procedure method adds items to the container object.

Syntax

Obj->[IDLitContainer::]Add, *Components*[, /NO_NOTIFY]

Arguments

Components

An object reference (or array of object references) to the IDLitComponent object or objects to be added to the container. When this method is called, the IDENTIFIER properties of objects specified by *Components* are validated, verifying that no items in the container have the same value. If an object with the same identifier already exists in the container, a unique identifier is created by appending a number to the original value.

Keywords

NO_NOTIFY

Normally, when an item is added to a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

Version History

6.0	Introduced
-----	------------

IDLitContainer::AddByIdentifier

The IDLitContainer::AddByIdentifier procedure method adds an object to the container hierarchy in the position specified by the *Identifier* argument.

Syntax

```
Obj->[IDLitContainer:]AddByIdentifier, Identifier, Item
    [, FOLDER_CLASSNAME=string]
```

Arguments

Identifier

An object identifier specifying the location in the container hierarchy where *Item* should be added. *Identifier* can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called. If *Identifier* is a null string (' '), *Item* is added to the root of the container object.

See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object identifier strings.

Item

An object reference to the iTool component object being added to the container.

Keywords

FOLDER_CLASSNAME

If the container hierarchy specified by *Identifier* contains subfolders that do not exist, the necessary subfolders are created automatically. By default, the created subfolders are of the same class as the calling method (IDLitContainer or one of its subclasses). To create subfolders of a different class, set the FOLDER_CLASSNAME keyword equal to a string specifying the name of the class to be used.

Version History

6.0	Introduced
6.2	Added FOLDER_CLASSNAME keyword

IDLitContainer::Cleanup

The IDLitContainer::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitContainer:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitContainer::FindIdentifiers

The IDLitContainer::FindIdentifiers function method allows you to retrieve the full identifiers for items within an iTool container.

Warning

The FindIdentifiers method recurses through the entire object hierarchy of the specified object, which may be slow for large container hierarchies. If you find it necessary to call FindIdentifiers multiple times, it may be more efficient to use a single call with one or more wildcards (“*”) to return all relevant identifiers, and then perform the necessary searches using the returned list.

Syntax

```
Result = Obj->[IDLitContainer::]FindIdentifiers([Pattern] [, COUNT=variable]
[, /LEAF_NODES] )
```

Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See [STRMATCH](#) for a description of the rules used when matching patterns.

Note

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

LEAF_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

Note

If all of the objects within a container are marked as PRIVATE, then that container is considered a leaf node. Only objects that subclass from IDLitComponent can be marked as private.

Version History

6.1	Introduced
-----	------------

See Also

[IDLitTool::FindIdentifiers](#)

IDLitContainer::Get

The IDLitContainer::Get function method retrieves items from the container.

Syntax

Result = Obj->[IDLitContainer::]Get([, /ALL] [, COUNT=*variable*] [, ISA=*string* or *array of strings*] [, POSITION=*index* or *array of indices*] [, /SKIP_PRIVATE])

Return Value

Returns an object reference or array of object references to the iTool components stored in the container. Unless either the ALL keyword or the POSITION keyword is specified, the first object in the container is returned. If no objects are found in the container, the return value is -1.

Arguments

None

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

SKIP_PRIVATE

Set this keyword to ignore any components for which the PRIVATE property is set to true. This keyword is ignored unless the ALL keyword is also set.

Version History

6.0	Introduced
-----	------------

IDLitContainer::GetByIdentifier

The `IDLitContainer::GetByIdentifier` function method retrieves an object from a container hierarchy using the specified identifier to locate the object.

Syntax

```
Result = Obj->[IDLitContainer::]GetByIdentifier(Identifier)
```

Return Value

Returns an object reference to the object that was requested from the hierarchy, or a null object reference if no object was located.

Arguments

Identifier

The object identifier of the object that should be retrieved from the container hierarchy. *Identifier* can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called.

See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object identifier strings.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitContainer::Init

The IDLitContainer::Init function method initializes the object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitContainer')
```

or

```
Result = Obj->[IDLitContainer::]Init() (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitContainer::Remove

The IDLitContainer::Remove procedure method removes items from the container.

Syntax

Obj->[IDLitContainer::Remove](#), *Components* [, /NO_NOTIFY]

Arguments

Components

An object reference (or array of object references) to the objects to be removed from the container.

Keywords

NO_NOTIFY

Normally, when an item is removed from a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, a REMOVEITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

Version History

6.0	Introduced
-----	------------

IDLitContainer::RemoveByIdentifier

The `IDLitContainer::RemoveByIdentifier` function method removes an object from a container hierarchy using the specified identifier to locate the object.

Syntax

Result = *Obj*->[IDLitContainer::]RemoveByIdentifier(*Identifier*)

Return Value

Returns an object reference to the object that was removed from the hierarchy, or a null object reference if no object was removed.

Arguments

Identifier

The object identifier of the object that should be removed from the container hierarchy. The *Identifier* argument can be either a fully-qualified object identifier (beginning with a “/” character) or a relative to the container on which this method is called.

See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object identifier strings.

6.0	Introduced
-----	------------

IDLitData

The IDLitData class provides a generic data storage object that can hold data items of any IDL data type. The IDLitData class provides typing and data change notification functionality, and when coupled with the IDLitDataContainer object forms the base element for the construction of composite data types.

The IDLitData class implements the iTools *notifier interface*, which provides a mechanism by which observers of a data item can be alerted when the state of the information contained in the data object changes.

This class is written in the IDL language. Its source code can be found in the file `idlitdata__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitData::Init](#)” on page 4732.

Properties

Objects of this class have the following properties. See “[IDLitData Properties](#)” on page 4722 for details on individual properties.

- [HIDE](#)
- [READ_ONLY](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of the superclass.

Methods

This class has the following methods:

- [IDLitData::AddDataObserver](#)
- [IDLitData::Cleanup](#)
- [IDLitData::Copy](#)
- [IDLitData::GetByType](#)
- [IDLitData::GetData](#)
- [IDLitData::GetProperty](#)
- [IDLitData::GetSize](#)
- [IDLitData::Init](#)
- [IDLitData::NotifyDataChange](#)
- [IDLitData::NotifyDataComplete](#)
- [IDLitData::RemoveDataObserver](#)
- [IDLitData::SetData](#)
- [IDLitData::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 3, “Data Management”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Removed NO_COPY property as it should only be documented as a keyword

IDLitData Properties

IDLitData objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitData::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitData::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitData::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [HIDE](#)
- [READ_ONLY](#)
- [TYPE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

HIDE

A Boolean value that controls the visibility of the data with respect to queries performed by the IDLitDataContainer methods GetData, SetData and GetIdentifiers. If the HIDE property has a True value, the data object is not found by these methods and the methods behave as if the data object did not exist.

Property Type	BOOLEAN		
Name String	HIDE		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

READ_ONLY

A Boolean value that controls the ability to modify the data with the `SetData` method. If the `READ_ONLY` property has a `True` value, an attempt to use `SetData` on the object fails. IDL prints an informational message in this case.

Property Type	BOOLEAN		
Name String	READ_ONLY		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TYPE

A scalar string containing the type of the data object. The default value of this property is `NULL (' ')` and cannot be changed after the class is instantiated. Subclasses of this class set the value of this property to a value that reflects the type of data that the subclass is implementing.

Property Type	STRING		
Name String	TYPE		
Get: Yes	Set: No	Init: Yes	Registered: Yes

IDLitData::AddDataObserver

The IDLitData::AddDataObserver procedure method specifies an object (the *Observer*) that will be notified when the contents of the data object are changed.

The object specified as the *Observer* must implement three methods that form the data observer interface:

- onDataChange
- onDataComplete
- onDataDelete

The onDataChange method is called when the contents of a data object are changed, and the onDataComplete method is called when the change messages are completed. This two-part notification process is used to allow observers of data to transact the change event and minimize the required system updates (such as graphic redrawing). The onDataDelete method is called when the data item is deleted.

Syntax

Obj->[IDLitData::]AddDataObserver, *Observer*

Arguments

Observer

An object reference to an iTool component object that implements the data observer interface methods. When the contained data value changes, the *Observer* is notified of this change.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::Cleanup

The IDLitData::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method removes all data stored in the IDLitData object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitData::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::Copy

The IDLitData::Copy function method returns an exact copy of the data object and its contents, including registered property values.

The following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

Note

If an object has been added to the data object, only the object reference to the added object is copied.

Syntax

Result = *Obj*->[IDLitData::]Copy()

Return Value

Returns a copy of the object on which it is called. If the copy operation fails, a null object is returned.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::GetByType

The IDLitData::GetByType function method returns all contained objects of the specified iTool data type.

Syntax

Result = *Obj*->[IDLitData::]GetByType(*Type*[, **COUNT**=*variable*])

Return Value

Returns an object array containing references to the contained data objects that are of the iTool data type specified by *Type*. If no objects matching *Type* exist, a null object reference is returned.

Arguments

Type

A string containing the iTool data type to search for in the data hierarchy rooted by this data container.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of valid objects returned by this method.

Version History

6.0	Introduced
-----	------------

IDLitData::GetData

The IDLitData::GetData function method retrieves the data stored in the object.

Syntax

```
Result = Obj->[IDLitData::]GetData(Data[, Identifier] [, NAN=variable]  
[, /NO_COPY])
```

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

A named variable that will contain the data retrieved from the data object. If the GetData method fails, the variable is not modified.

Identifier

A string argument that is not used by this method, but is accepted for parameter compatibility with the IDLitDataContainer::GetData method. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

Keywords

NAN

Set this keyword to a named variable that will contain 1 if *Data* contains any non-finite values (either NaN or Infinity), or 0 otherwise.

NO_COPY

Set this keyword to move the data from the data object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

Version History

6.0	Introduced
-----	------------

IDLitData::GetProperty

The IDLitData::GetProperty procedure method retrieves the value of an IDLitData property, and should be called by the GetProperty method of any subclass of this class.

Syntax

Obj->[IDLitData:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitData Properties](#)” on page 4722 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitData::GetSize

The IDLitData::GetSize function method returns an approximate value for the amount of memory being used by the data object.

Syntax

Result = *Obj*->[IDLitData:]GetSize()

Return Value

Returns the number of bytes of memory used by the data object. The returned value is an approximation.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::Init

The IDLitData::Init function method initializes the IDLitData object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitData'[, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitData::]Init([Data] [, PROPERTY=value]) (In a lifecycle  
method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

An IDL variable of any type that is stored in the data object.

Keywords

Any property listed under “IDLitData Properties” on page 4722 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitData::NotifyDataChange

The IDLitData::NotifyDataChange procedure method is called when a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataComplete method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the onDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' onDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

Note

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

Syntax

Obj->[IDLitData:]NotifyDataChange

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::NotifyDataComplete

The IDLitData::NotifyDataComplete procedure method is called after a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataChange method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the onDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' onDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

Note

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

Syntax

Obj->[IDLitData:]NotifyDataComplete

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::RemoveDataObserver

The IDLitData::RemoveDataObserver method unregisters an object that has been registered as an *observer* of this data object. After this method is called, the Observer will no longer be notified when the contents of the data object change. If the specified *Observer* doesn't exist, this method will return quietly.

Syntax

Obj->[IDLitData:]RemoveDataObserver, *Observer*

Arguments

Observer

An object reference to an iTool component object that was previously registered as an observer of this data object.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitData::SetData

The IDLitData::SetData function method copies the data from an IDL variable or expression into the data object, and notifies all its observers that the data has changed.

Syntax

```
Result = Obj->[IDLitData::]SetData(Data[, Identifier] [, /NO_COPY] [, /NULL])
```

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

An IDL variable or expression whose value is copied into the data object.

Identifier

A string argument that is not used by this method. It is accepted by this method only for parameter compatibility with IDLitDataContainer::SetData. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

Keywords

NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored.

Version History

6.0	Introduced
-----	------------

IDLitData:: SetProperty

The IDLitData::SetProperty procedure method sets the value of an IDLitData property, and should be called by the SetProperty method of any subclass of this class.

Syntax

Obj->[IDLitData::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitData Properties](#)” on page 4722 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer

The IDLitDataContainer class is used to store collections of IDLitData and IDLitDataContainer objects to form hierarchical data structures. Objects can be added to and removed from an IDLitDataContainer at any time, allowing for the dynamic creation of composite data types.

Objects stored in an IDLitDataContainer hierarchy are referenced using iTool *object identifiers*. Object identifiers are simple scalar strings assigned to the IDENTIFIER property of an object when it is created. For a complete discussion of object identifiers and their role in the iTool system, see “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*).

This class is written in the IDL language. Its source code can be found in the file `idlitdatacontainer__define.pro` in the `lib/itool/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitContainer](#)

[IDLitData](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitDataContainer::Init](#)” on page 4750.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitDataContainer::Add](#)
- [IDLitDataContainer::Cleanup](#)

- [IDLitDataContainer::GetData](#)
- [IDLitDataContainer::GetIdentifiers](#)
- [IDLitDataContainer::GetProperty](#)
- [IDLitDataContainer::Init](#)
- [IDLitDataContainer::SetData](#)
- [IDLitDataContainer::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 3, “Data Management”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDLitContainer](#)
- [IDLitData](#)

IDLitDataContainer::Add

The IDLitDataContainer::Add procedure method adds items to the data container object, and sends out an onDataChange and onDataComplete messages to all observers of the data container.

Syntax

```
Obj->[IDLitDataContainer::]Add, Data [, /NO_NOTIFY]
```

Arguments

Data

An object reference (or array of object references) to the IDLitData object or objects to be added to the container. Objects that are not of class IDLitData are quietly ignored.

Keywords

NO_NOTIFY

Normally, when an item is added, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no ADDITEMS message is sent.

Note

Regardless of the setting of NO_NOTIFY, the onDataChange and onDataComplete messages are always sent.

Version History

6.1	Introduced
-----	------------

IDLitDataContainer::Cleanup

The IDLitDataContainer::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method destroys all data objects stored in this container.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDataContainer::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitDataContainer::GetData

The `IDLitDataContainer::GetData` function method retrieves the data value contained in the data object specified by the *Identifier* argument.

Syntax

```
Result = Obj->[IDLitDataContainer:]GetData(Data [, Identifier] [, /NO_COPY])
```

Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

Arguments

Data

A named variable that will contain the data value of the specified data object.

Identifier

A string containing the relative object identifier path to the target data object for this method. See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object identifier strings.

If *Identifier* is not set, or is set to a null string, the data contained in the data container itself is returned.

Keywords

NO_COPY

Set this keyword to move the data from the data container object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer::GetIdentifiers

The IDLitDataContainer::GetIdentifiers function method retrieves the object identifiers for all data and data container objects contained in the data container object.

Syntax

```
Result = Obj->[IDLitDataContainer::]GetIdentifiers([Pattern] [, /LEAF_NODES])
```

Return Value

Returns an array of strings containing the object identifiers for all data and data container objects contained by the data container object. If the container is empty, or if the *Pattern* argument is supplied and no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. See [STRMATCH](#) for a description of the rules used when matching patterns.

Keywords

LEAF_NODES

Set this keyword to return only object identifiers whose final node is *not* a container object.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer::GetProperty

The IDLitDataContainer::GetProperty procedure method retrieves the value of an IDLitDataContainer property, and should be called by the GetProperty method of any subclass of this class.

Syntax

Obj->[IDLitDataContainer::](#)GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 4744 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer::Init

The IDLitDataContainer::Init function method initializes the IDLitDataContainer object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitDataContainer'[, Data] [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitDataContainer::]Init([Data] [, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Data

An IDL variable of any type or shape that is stored into the object at initialization.

Keywords

Any property listed under “IDLitDataContainer Properties” on page 4744 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer::SetData

The IDLitDataContainer::SetData function method stores data in the IDLitData object specified by *Identifier*. This method acts in exactly the same way as the IDLitData::SetData method.

Syntax

```
Result = Obj->[IDLitDataContainer::]SetData(Data, Identifier[, /NO_COPY]
[, /NULL])
```

Return Value

Returns a 1 if the operation succeeds, or 0 if it fails.

Arguments

Data

An IDL variable of any type that is copied into the specified data object.

Identifier

A scalar string containing the object identifier of the IDLitData object in which the data specified by *Data* should be stored. This path must specify a valid IDLitData object, or the function fails. See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object identifier strings.

Keywords

NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored, but must still be present.

Version History

6.0	Introduced
-----	------------

IDLitDataContainer:: SetProperty

The IDLitDataContainer:: SetProperty procedure method sets the value of an IDLitDataContainer property, and should be called by the SetProperty method of any subclass of this class.

Syntax

Obj->[IDLitDataContainer::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLitDataContainer Properties](#)” on page 4744 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitDataOperation

The IDLitDataOperation class is a subclass of IDLitOperation that automates data access and automatically records information for the undo-redo system. By automating this functionality, the IDLitDataOperation class eliminates much of the work required to implement a standard subclass of the IDLitOperation class. See [IDLitOperation](#) for additional information on iTool operations.

Note

The IDLitDataOperation class is designed for use in operations that affect data values. If you are creating an operation that acts on items other than the data that underlies a visualization, you should base your operation class on the IDLitOperation class.

While the implementation of a standard subclass of an IDLitOperation class requires the developer to provide implementations of the DoAction, UndoOperation, and RedoOperation methods, the IDLitDataOperation class provides these methods automatically. The only method the developer of an IDLitDataOperation class is *required* to implement is the Execute method, which contains the logic for the specific operation being performed. Depending on the operation being performed, the developer of an IDLitDataOperation may also implement methods to undo the operation, display a user interface before performing the operation, get and set properties specific to the operation, and initialize the IDLitDataOperation object.

When an IDLitDataOperation is requested by a user, the following things occur:

1. As with any operation, execution commences when the DoAction method is called on this object. When called, the IDLitDataOperation retrieves the currently-selected items. If nothing is selected, the operation returns.
2. For each selected item, the data objects of the parameters registered as “operation targets” are retrieved.
3. The data objects are queried for iTool data types that match the types supported by the IDLitDataOperation.

For each data object that includes data of an iTool data type supported by the IDLitDataOperation, the following things occur:

1. The data from the data object is retrieved.
2. If the IDLitDataOperation does not have the REVERSIBLE_OPERATION property set, a copy of the data is created and placed into the undo-redo command set.

3. The Execute method is called, with the retrieved data as its argument.
4. If the Execute method succeeds and the IDLitDataOperation has the EXPENSIVE_COMPUTATION property set, a copy of the results is placed into the undo-redo command set.
5. The result of the IDLitDataOperation is placed in the data object. This action will cause all visualization items that use the data object to update when the operation is completed.

Once all selected data items have been processed, the undo-redo command set is placed into the system undo-redo buffer for later use.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*).

This class is written in the IDL language. Its source code can be found in the file `idlitdataoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitOperation](#)

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitDataOperation::Init”](#) on page 4765.

Properties

Objects of this class have the following properties. See [“IDLitDataOperation Properties”](#) for details on individual properties.

- [WITHIN_UI](#)

Methods

This class has the following methods:

- [IDLitDataOperation::Cleanup](#)

- [IDLitDataOperation::DoExecuteUI](#)
- [IDLitDataOperation::Execute](#)
- [IDLitDataOperation::GetProperty](#)
- [IDLitDataOperation::Init](#)
- [IDLitDataOperation::SetProperty](#)
- [IDLitDataOperation::UndoExecute](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

See “[Creating a New Data-Centric Operation](#)” (Chapter 7, *iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Added WITHIN_UI property

[IDLitOperation](#)

IDLitDataOperation Properties

IDLitDataOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitDataOperation::GetProperty](#).

Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitDataOperation::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitDataOperation::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [WITHIN_UI](#)

In addition, objects of this class inherit properties from the following superclass:

- [IDLitOperation](#)

WITHIN_UI

A Boolean value that indicates whether the operation is currently within the [IDLitDataOperation::DoExecuteUI](#) method (i.e., it is currently displaying a dialog). This property is automatically set to one (True) just before the method is called, and is reset to zero (False) after the method returns.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLitDataOperation::Cleanup

The IDLitDataOperation::Cleanup procedure method performs all cleanup on the object.

Note

An operation based on the IDLitDataOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDataOperation::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitDataOperation::DoExecuteUI

The IDLitDataOperation::DoExecuteUI function method provides a way for the iTool developer to request user input before performing an operation. If the [SHOW_EXECUTION_UI](#) property is set, this method will be called before the operation's Execute method is called.

Note

Every operation based directly on the IDLitDataOperation class that requires user interaction before execution must implement its own DoExecuteUI method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer's Guide*) for details.

The DoExecuteUI method itself can present any interface. In practice, most iTool DoExecuteUI methods use the IDLitTool::DoUIService method to display a user interface requesting user input. User interfaces and UI Services are discussed in [Chapter 11, “iTool User Interface Architecture”](#) (*iTool Developer's Guide*).

Warning

If the DoExecuteUI method does not return success, the Execute method will not be called.

Syntax

Result = *Obj*->[IDLitDataOperation::]DoExecuteUI()

Return Value

Returns a 1 if the displayed user interface code executed successfully, and the operation should be executed. If user interface code does not execute successfully, or if the user cancels the operation, this function returns a 0.

Arguments

None

Keywords

None

Example

The following is an example of a DoExecuteUI method, taken from the iTools “Scale Factor” operation:

```
FUNCTION IDLitopScalefactor::DoExecuteUI

oTool = self->GetTool()
IF (oTool EQ OBJ_NEW()) THEN RETURN, 0

RETURN, oTool->DoUIService('ScaleFactor', self)

END
```

This implementation of the DoExecuteUI method does the following:

1. Retrieves an object reference to the current iTool using the GetTool method.
2. Checks to make sure the returned object reference is not a null object (which would be the case if the GetTool method failed).
3. Calls the ScaleFactor UI Service.

Version History

6.0	Introduced
-----	------------

IDLitDataOperation::Execute

The IDLitDataOperation::Execute function method contains the execution logic for the operation. This method is called automatically when the iTool user requests an operation based on the IDLitDataOperation class.

Note

Every operation based directly on the IDLitDataOperation class must implement its own Execute method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

When the iTool system executes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the Execute method. This means that the Execute method itself does not need to “unpack” a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type IDLARRAY2D, the iTool system will include the selected two-dimensional array as the *Data* argument.

Syntax

```
Result = Obj->[IDLitDataOperation:]Execute(Data)
```

Return Value

The return value is 1 if the operation executed successfully, or 0 otherwise.

Arguments

Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

Keywords

None

Version History

6.0	Introduced
-----	------------

See Also

[IDLitDataOperation::UndoExecute](#)

IDLitDataOperation::GetProperty

The IDLitDataOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

Note

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Syntax

```
Obj->[IDLitDataOperation::]GetProperty[, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under “[IDLitDataOperation Properties](#)” on page 4758 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj->IDLitDataOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

Version History

6.0	Introduced
-----	------------

IDLitDataOperation::Init

The IDLitDataOperation::Init function method initializes the IDLitDataOperation object and sets properties that define the behavior the operation provides.

Note

An operation based on the IDLitDataOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitDataOperation' [, PROPERTY=variable] )
```

or

```
Result = Obj->[IDLitDataOperation::]Init([, PROPERTY=variable]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitDataOperation Properties](#)” on page 4758 that contains the word “Yes” in the “Init” column of the properties table can be initialized

during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal the appropriate property value.

-----	------------

IDLitDataOperation:: SetProperty

The IDLitDataOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

Note

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Syntax

Obj->[\[IDLitDataOperation::\]](#)SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under [“IDLitDataOperation Properties”](#) on page 4758 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitDataOperation::UndoExecute

The `IDLitDataOperation::UndoExecute` function method is called when a user selects the Undo operation after executing an `IDLitDataOperation` that sets the value of the `REVERSIBLE_OPERATION` property to 1. (If the `IDLitDataOperation` does not set this property, the `UndoExecute` method is not called.) If implemented, this method generally applies the inverse of the operation performed by the `Execute` method.

Note

An operation based on the `IDLitDataOperation` class *must* implement this method if the operation sets the `REVERSIBLE_OPERATION` property. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

When the iTool system undoes an `IDLitDataOperation`, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the `UndoExecute` method. This means that the `UndoExecute` method itself does not need to “unpack” a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type `IDLARRAY2D`, the iTool system will include the selected two-dimensional array as the *Data* argument.

Syntax

```
Result = Obj->[IDLitDataOperation:]UndoExecute(Data)
```

Return Value

The return value is 1 if the operation was undone successfully, or 0 otherwise.

Arguments

Data

A single data item on which the operation should be performed. Note that *Data* is *not* an `IDLitData` object, but actual data.

Keywords

None

[IDLitDataOperation::Execute](#)

IDLitDirectWindow

An IDLitDirectWindow object is a representation of an on-screen area on a display device that serves as a graphics destination. In contrast to [IDLgrWindow](#) and [IDLitWindow](#), the IDLitDirectWindow uses Direct Graphics.

Important! You must note the following:

- The IDLitDirectWindow is designed for use only with the Export Bridge. The event notification methods will be called automatically by the Export Bridge, but will not be called when the IDLitDirectWindow class is used in other contexts. For more information, see “[Exporting Drawable Objects](#)” (Chapter 11, *IDL Connectivity Bridges*).
- Objects or subclasses of this type can not be saved or restored.
- If you are using a multi-monitor setup on X (under UNIX), you cannot have the window on the second monitor. For more information, see “[UNIX Multi-Monitor Configurations](#)” (Chapter 5, *Using IDL*).

Superclasses

[IDLitComponent](#)

Creation

See [IDLitDirectWindow::Init](#).

Properties

Objects of this class have the following properties. See “[IDLitDirectWindow Properties](#)” on page 4772 for details on individual properties.

- [WINDOW_INDEX](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLitDirectWindow::Cleanup](#)
- [IDLitDirectWindow::GetProperty](#)

- [IDLitDirectWindow::Init](#)
- [IDLitDirectWindow::MakeCurrent](#)
- [IDLitDirectWindow::OnEnter](#)
- [IDLitDirectWindow::OnExit](#)
- [IDLitDirectWindow::OnExpose](#)
- [IDLitDirectWindow::OnKeyboard](#)
- [IDLitDirectWindow::OnMouseDown](#)
- [IDLitDirectWindow::OnMouseMove](#)
- [IDLitDirectWindow::OnMouseUp](#)
- [IDLitDirectWindow::OnResize](#)
- [IDLitDirectWindow::OnWheel](#)
- [IDLitDirectWindow::SetProperty](#)

Version History

6.3	Introduced
6.4	Added OnWheel method

IDLitDirectWindow Properties

IDLitDirectWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitDirectWindow::GetProperty](#).

Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitDirectWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitDirectWindow::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [WINDOW_INDEX](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)

WINDOW_INDEX

An integer containing the window index associated with the window.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLitDirectWindow::Cleanup

The IDLitDirectWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitDirectWindow::]Cleanup (*In a lifecycle method only*)

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::GetProperty

The IDLitDirectWindow::GetProperty procedure method retrieves the value of an IDLitDirectWindow property, and should be called by a subclass's GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitDirectWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under IDLitDirectWindow Properties that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::Init

The IDLitDirectWindow::Init function method initializes the window object.

This function method initializes the IDLitDirectWindow object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitDirectWindow'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitDirectWindow::]Init([, PROPERTY=value]) (In a lifecycle method only)
```

Arguments

None

Keywords

Any property listed under IDLitDirectWindow Properties that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::MakeCurrent

The IDLitDirectWindow::MakeCurrent procedure method sets the current graphics device to the window device and sets the current output window to the IDLitDirectWindow's window.

The IDLitDirectWindow::MakeCurrent method should be called before sending any Direct Graphics commands, to ensure that the graphics appears in the appropriate window.

Syntax

```
Obj->[IDLitDirectWindow::]MakeCurrent
```

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnEnter

The IDLitDirectWindow::OnEnter procedure method handles notification from the window that a mouse enter event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[\[IDLitDirectWindow::\]](#)OnEnter

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnExit

The IDLitDirectWindow::OnExit procedure method handles notification from the window that a mouse exit event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnExit

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnExpose

The `IDLitDirectWindow::OnExpose` procedure method handles notification from the window that an expose event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the `OnExpose` method will automatically redraw the window. If you are using a subclass of `IDLitDirectWindow` and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see “[Exporting Drawable Objects](#)” (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[[IDLitDirectWindow::](#)]OnExpose, *X*, *Y*, *Width*, *Height*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Width

A floating-point value representing the width of the newly exposed portion of the canvas (in device coordinates).

Height

A floating-point value representing the height of the newly exposed portion of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnKeyboard

The `IDLitDirectWindow::OnKeyboard` procedure method handles notification from the window that a keyboard event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLitDirectWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->`[IDLitDirectWindow::]OnKeyboard, IsASCII, Character, KeySymbol, X, Y, Press, Release, Modifiers`

Arguments

IsASCII

A scalar byte value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to a byte value corresponding to the character of the pressed key. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to a byte value corresponding to the ASCII character of the key that was pressed. Otherwise, this argument is set to zero.

KeySymbol

If *IsASCII* is zero, this argument is set to a long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

1	Shift
2	Control

3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

X,Y

Long integers containing the x -coordinate and y -coordinate of the mouse cursor (in device coordinates) at the time of the event.

Press

A long integer indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

Release

A long integer indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-1: Modifier Values

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnMouseDown

The `IDLitDirectWindow::OnMouseDown` procedure method handles notification from the window that a mouse down event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLitDirectWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->`[IDLitDirectWindow::]OnMouseDown, X, Y, ButtonMask, Modifiers, NumClicks`

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 32-2: Bitmask for Button Events

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-3: Bits of the Modifier Key Mask

NumClicks

An integer indicating the number of times the mouse button was clicked.

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnMouseMotion

The `IDLitDirectWindow::OnMouseMotion` procedure method handles notification from the window that a mouse motion event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLitDirectWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->`[IDLitDirectWindow::]OnMouseMotion, X, Y, Modifiers`

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-4: Bits of the Modifier Key Mask

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnMouseUp

The IDLitDirectWindow::OnMouseUp procedure method handles notification from the window that a mouse up event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitDirectWindow, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnMouseUp, *X*, *Y*, *ButtonMask*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was released:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 32-5: Bitmask for Button Events

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnResize

The IDLitDirectWindow::OnResize procedure method handles notification from the window that a resize event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. By default, the OnResize method will automatically resize the window. If you are using a subclass of IDLitDirectWindow and require additional functionality, you should override this method. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitDirectWindow::]OnResize, *Width*, *Height*

Arguments

Width

A floating-point value representing the new width of the canvas (in device coordinates).

Height

A floating-point value representing the new height of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitDirectWindow::OnWheel

The `IDLitDirectWindow::OnWheel` procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of `IDLitDirectWindow`, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[`IDLitDirectWindow::`]OnWheel, *X, Y, Delta, Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel towards the front of the mouse generates positive values, pulling the wheel towards the back of the mouse generates negative values. The magnitude of the value depends on the device setting for the individual mouse.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-6: Modifier Values

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLitDirectWindow::SetProperty

The IDLitDirectWindow::SetProperty procedure method sets the value of an IDLitDirectWindow property, and should be called by a subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitDirectWindow::]SetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under IDLitDirectWindow Properties that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

IDLitIMessaging

The IDLitIMessaging interface class provides a set of methods used to allow an object that implements the interface to send notification messages and to react appropriately when notification messages are received from other iTool component objects. This class also provides methods that allow the iTool developer to notify the iTool user of error conditions via graphical dialogs, to prompt the user for input, and to retrieve a reference to the current iTool object.

IDLitIMessaging objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Note

In the iTools system, management of messages is handled by the IDLitVisualization class, of which the IDLitIMessaging class is a superclass. In practice, this means that if you need to override any methods of the IDLitIMessaging class, you will do so in the definition of your visualization class.

This class is written in the IDL language. Its source code can be found in the file `idlitimessaging__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

None

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

Objects of this class are not created as standalone objects.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- `IDLitIMessaging::AddOnNotifyObserver`
- `IDLitIMessaging::DoOnNotify`
- `IDLitIMessaging::ErrorMessage`
- `IDLitIMessaging::GetTool`
- `IDLitIMessaging::ProbeStatusMessage`
- `IDLitIMessaging::ProgressBar`
- `IDLitIMessaging::PromptUserText`
- `IDLitIMessaging::PromptUserYesNo`
- `IDLitIMessaging::RemoveOnNotifyObserver`
- `IDLitIMessaging::SignalError`
- `IDLitIMessaging::StatusMessage`

Version History

6.0	Introduced
-----	------------

IDLitIMessaging Properties

Objects of this class have no properties of their own.

IDLitMessaging::AddOnNotifyObserver

The `IDLitMessaging::AddOnNotifyObserver` procedure method is used to register a specified iTool component object to receive messages generated by the `DoOnNotify` method of another specified iTool component object.

Syntax

Obj->[IDLitMessaging::AddOnNotifyObserver](#), *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the `OnNotify` callback method, which is called when a notification message is dispatched to *IdObserver* by the `DoOnNotify` method of another iTool component object (usually the object specified by *IdSubject*). The `OnNotify` method has the following signature:

```
PRO ::OnNotify, idOriginator, idMessage, message
```

where

- *idOriginator* is the object identifier of the iTool component that is the source of the message
- *idMessage* is a string that identifies the type of message being sent
- *message* is the message itself.

In general, the *idMessage* string is used by the `OnNotify` method to determine what type of action to take. See “[IDLitMessaging::DoOnNotify](#)” on page 4799 for additional details.

IdSubject

A string value identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via [IDLitMessaging::DoOnNotify](#) specifies *IdSubject* as the originator, the *IdObserver* object’s `OnNotify` method is called.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitMessaging::DoOnNotify

The `IDLitMessaging::DoOnNotify` procedure method is used to broadcast a notification message to iTool component objects that are observing the source of the message.

See the “[IDLitMessaging::AddOnNotifyObserver](#)” on page 4797, and “[IDLitMessaging::RemoveOnNotifyObserver](#)” on page 4809 methods for more information on notification messages.

See “[iTool Messaging System](#)” (Chapter 2, *iTool Developer’s Guide*) for a more in-depth discussion of notification.

Syntax

Obj->[\[IDLitMessaging::\]DoOnNotify](#), *IdOriginator*, *IdMessage*, *Value*

Arguments

IdOriginator

A string value identifying the item that is the source of the message. Normally, *IdOriginator* is the object identifier of the object that calls this method, but it can be any string value.

IdMessage

A string that will uniquely identify the message being sent. The value of *IdMessage* is determined by the iTool developer; it is used by the `OnNotify` methods of any observer objects to determine what type of message has been received, and to act accordingly. For example, if a property value has changed, this argument might be set to the string `SETPROPERTY`.

Value

Any value that is associated with the message being sent. For example, if a `SETPROPERTY` message was sent, *Value* might contain the name of the property changed. If no value is associated with the message, set this argument to a null string (‘’).

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitMessaging::ErrorMessage

The IDLitMessaging::ErrorMessage procedure method is used to display an error message to the user.

The actual method used to display the message to the user depends on the user interface in use. Normally, this method will display a modal dialog.

Syntax

```
Obj->[IDLitMessaging::]ErrorMessage, StrMessage[, SEVERITY=integer]  
[, TITLE=string] [, /USE_LAST_ERROR]
```

Arguments

StrMessage

A scalar string or string array containing a description of the error.

Keywords

SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

USE_LAST_ERROR

If this keyword is set, the system will use the information that was part of the last error signaled to the iTool. The last error may have been set either by a previous call to this method or by a call to the [IDLitMessaging::SignalError](#) method.

Version History

6.0	Introduced
-----	------------

IDLitIMessaging::GetTool

The IDLitIMessaging::GetTool function method returns an object reference to the iTool object associated with the object on which it is called.

Syntax

Result = *Obj*->[\[IDLitIMessaging::\]GetTool\(\)](#)

Return Value

Returns an object reference to the iTool object associated with the object on which the GetTool is called. If the object is not contained by an iTool, this function returns a null object reference.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitMessaging::ProbeStatusMessage

The IDLitMessaging::ProbeStatusMessage procedure method is used to display a status message to the user, which is displayed in a data-specific region of the user interface. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower right corner of the iTool window.

Syntax

Obj->[\[IDLitMessaging::\]ProbeStatusMessage](#), *StrMessage*

Arguments

StrMessage

A scalar string that is displayed in the data-specific status area.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitIMessaging::ProgressBar

The IDLitIMessaging::ProgressBar function method is used to display a progress bar to the user and update the displayed values.

On the initial call to this method, a dialog is displayed. The dialog remains active until the method is called with the /SHUTDOWN keyword.

The actual method used to display the message to the user depends on the user interface in use. Normally, the progress bar is displayed as a modal dialog.

Syntax

```
Result = Obj->[IDLitIMessaging::]ProgressBar(StrMessage [, CANCEL=string]
[, PERCENT=value] [, /SHUTDOWN])
```

Return Value

Returns 1 if the progress bar was displayed successfully, or 0 otherwise.

Arguments

StrMessage

A scalar string or string array containing a description of the action taking place.

Keywords

CANCEL

Set this keyword to a string containing the text for the Cancel button on the Progress Bar. If this keyword is not specified, or is set to a null string, then the string “Cancel” is used.

PERCENT

Set this keyword to a value between 0 and 100 that represents the “percentage complete” value to be shown on the progress bar.

SHUTDOWN

If set, any progress bar that is being displayed is removed from the user interface.

Version History

6.0	Introduced
6.1	Added CANCEL keyword

IDLitIMessaging::PromptUserText

The IDLitIMessaging::PromptUserText function method is used to prompt the iTool user with a question and retrieve a text answer. The text answer is returned to the caller of this method via a supplied IDL variable.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

Syntax

```
Result = Obj->[IDLitIMessaging::]PromptUserText(StrPrompt, Answer  
[, TITLE=string])
```

Return Value

Returns 1 if the prompt was displayed and the user clicked the **OK** button. If the user clicks the **Cancel** button or dismisses the dialog, the return value is 0.

Arguments

StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

Answer

A named variable that will contain the string value entered by the user.

Keywords

TITLE

Set this keyword to a string representing the title of the prompt. This value is placed in the title bar of the modal dialog.

Version History

6.0	Introduced
-----	------------

IDLitMessaging::PromptUserYesNo

The IDLitMessaging::PromptUserYesNo function method is used to prompt the user with a yes or no question and return an answer.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

Syntax

```
Result = Obj->[IDLitMessaging::]PromptUserYesNo(StrPrompt, Answer  
[, TITLE=string])
```

Return Value

Returns 1 if the dialog executed properly and returned a value in the variable specified. You must check the value stored in the variable specified as the *Answer* argument to determine which button the user pressed.

Arguments

StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

Answer

A named variable that will contain 1 if the user answered Yes to the prompt and 0 if the user answered No.

Keywords

TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

-----	------------

IDLitMessaging::RemoveOnNotifyObserver

The `IDLitMessaging::RemoveOnNotifyObserver` procedure method is used to unregister a specified iTool component object as wishing to receive messages generated by the `DoOnNotify` method of another specified iTool component object. This method reverses the action of calling the `IDLitMessaging::AddOnNotifyObserver` method.

Syntax

Obj->`[IDLitMessaging:]RemoveOnNotifyObserver, IdObserver, IdSubject`

Arguments

IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can be any scalar string.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitMessaging::SignalError

The IDLitMessaging::SignalError procedure method is used to signal an error in the system. No user interface is displayed to the user, but the error is registered with the system, made the current error, and recorded by the iTool log service (if enabled).

Note

If this method is used to signal an error, the [IDLitMessaging::ErrorMessage](#) method can be called with the /USE_LAST_ERROR keyword to use the information set by this method.

Syntax

```
Obj->[IDLitMessaging::]SignalError, StrMessage [, CODE=integer]
[, SEVERITY=integer]
```

Arguments

StrMessage

A scalar string or string array containing a description of the error.

Keywords

CODE

Set this keyword to an integer that represents an error code that can be associated with the error. Error codes can be any integer value specified by the iTool developer.

SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

Version History

6.0	Introduced
-----	------------

IDLitMessaging::StatusMessage

The `IDLitMessaging::StatusMessage` procedure method is used to display a status message to the user. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower left corner of the iTool window.

Syntax

```
Obj->[IDLitMessaging::]StatusMessage, StrMessage
[, SEGMENT_IDENTIFIER=string]
```

Arguments

StrMessage

A scalar string that is displayed as a status message to the user.

Keywords

SEGMENT_IDENTIFIER

Set this keyword to a string containing the relative identifier of the status bar segment in which the message is to be displayed. By default, iTools have two status bar segments, as described in “[Status Messages](#)” (Chapter 12, *iTool Developer’s Guide*). By default, the `StatusMessage` method changes the value of the Status segment; that segment’s identifier is `'MESSAGE'`.

To change the value of the Probe Status segment, use the segment identifier `'PROBE'`. Alternately, you can use the `IDLitMessaging::ProbeStatusMessage` method.

Version History

6.0	Introduced
6.1	Added <code>SEGMENT_IDENTIFIER</code> keyword

IDLitManipulator

The IDLitManipulator class provides the base functionality of the iTools manipulator system. Most automation and functional capabilities of the manipulator system are provided by this class. Tasks performed by this class include:

- Selection operations and associated selection state management.
- Automated mouse cursor management (changing the cursor as the mouse traverses different items in the current visualization).
- System event settings management.
- Coordination between the manipulator and manipulator visualization system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulator__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Note

See [Chapter 8, “Creating a Manipulator”](#) (*iTool Developer’s Guide*) for information on creating a custom manipulator.

Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitManipulator::Init”](#) on page 4828.

Properties

Objects of this class have the following properties. See [“IDLitManipulator Properties”](#) on page 4816 for details on individual properties.

- [BUTTON_EVENTS](#)

- `DEFAULT_CURSOR`
- `DESCRIPTION`
- `DISABLE`
- `KEYBOARD_EVENTS`
- `MOTION_EVENTS`
- `OPERATION_IDENTIFIER`
- `PARAMETER_IDENTIFIER`
- `TRANSIENT_DEFAULT`
- `TRANSIENT_MOTION`
- `TYPES`
- `VIEWS_ONLY`
- `VISUAL_TYPE`

In addition, objects of this class inherit the properties of the superclass of this class.

Methods

This class has the following methods:

- `IDLitManipulator::Cleanup`
- `IDLitManipulator::CommitUndoValues`
- `IDLitManipulator::GetCursorType`
- `IDLitManipulator::GetProperty`
- `IDLitManipulator::Init`
- `IDLitManipulator::OnKeyboard`
- `IDLitManipulator::OnLoseCurrentManipulator`
- `IDLitManipulator::OnMouseDown`
- `IDLitManipulator::OnMouseMove`
- `IDLitManipulator::OnMouseUp`
- `IDLitManipulator::OnWheel`
- `IDLitManipulator::RecordUndoValues`
- `IDLitManipulator::RegisterCursor`

- [IDLitManipulator::SetCurrentManipulator](#)
- [IDLitManipulator::SetProperty](#)

In addition, this class inherits the methods of its superclass.

Examples

See [Chapter 8, “Creating a Manipulator”](#) (*iTool Developer’s Guide*) for examples.

Version History

6.0	Introduced
6.4	Added OnWheel method

IDLitManipulator Properties

IDLitManipulator objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitManipulator::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitManipulator::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitManipulator::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [BUTTON_EVENTS](#)
- [DEFAULT_CURSOR](#)
- [DESCRIPTION](#)
- [DISABLE](#)
- [KEYBOARD_EVENTS](#)
- [MOTION_EVENTS](#)
- [OPERATION_IDENTIFIER](#)
- [PARAMETER_IDENTIFIER](#)
- [TRANSIENT_DEFAULT](#)
- [TRANSIENT_MOTION](#)
- [TYPES](#)
- [VIEWS_ONLY](#)
- [VISUAL_TYPE](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)
- [IDLitMessaging](#)

BUTTON_EVENTS

A boolean value controlling whether mouse button events are generated. If set, mouse button up and button down events will be dispatched to this manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DEFAULT_CURSOR

A string containing the name of the default cursor for the manipulator. This is the name of the cursor that is displayed if no items are hit during mouse cursor motion. The default manipulator cursor is set to 'ARROW'. Allowable values are:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

Note

Set a pre-defined default cursor using the `Init` or `SetProperty` method. Set a custom cursor as the default cursor using the `IDLitManipulator::RegisterCursor` method's `DEFAULT` keyword.

DESCRIPTION

A string representing the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

DISABLE

A boolean value indicating that the manipulator should be disabled. Disabling a manipulator prevents it from being chosen by a user or by the iTool system. The default value is 0b (false).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

KEYBOARD_EVENTS

A boolean value controlling whether keyboard events are generated. If set, keyboard events will be dispatched to the manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MOTION_EVENTS

A boolean value controlling whether motion events are generated. If set, motion events will be dispatched to this manipulator. These events are enabled by default.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

OPERATION_IDENTIFIER

A string identifier for the operation that is associated with the manipulator. This identifier specifies the operation that is used by the undo-redo system to transact the actions performed by this manipulator. If not specified, the manipulator actions are not recorded by the undo-redo system.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

See [“Manipulators and the Undo/Redo System”](#) (Chapter 8, *iTool Developer’s Guide*) for information on configuring a custom manipulator to support undo/redo operations.

PARAMETER_IDENTIFIER

A string identifier specifying which parameter the operation should query when transacting the manipulator. If specified, this identifier is used in conjunction with the operation specified by the OPERATION_IDENTIFIER property to transact the operations performed by a manipulator. The parameter is primarily used to specify the property identifier for manipulators that change the values of properties.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

See [“Retrieving Property Information”](#) (Appendix A, *iTool Developer’s Guide*) for more information about property identifiers and names. See [“Manipulators and the Undo/Redo System”](#) (Chapter 8, *iTool Developer’s Guide*) for information on configuring a custom manipulator to support undo/redo operations.

TRANSIENT_DEFAULT

An integer value used to indicate that the manipulator is *transient*, which causes the system to automatically switch to the default manipulator when this manipulator’s

mouse actions are complete (that is, when the `OnMouseUp` method has been called) or when an end-of-keyboard-entry character (carriage return or escape key) is detected. The default value is 0.

This property can be set to any of the following values:

- 0 = No transient behavior
- 1 = Mouse transient behavior is enabled. When a mouse button up is detected, the manipulation system will switch to the default manipulator for the system
- 2 = Keyboard transient behavior is enabled. When a carriage return or escape key is pressed, the system will switch to the default manipulator for the system
- 3 = Both keyboard and mouse transient behavior are enabled

Property Type	Enumerated List		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TRANSIENT_MOTION

A boolean value controlling whether transient motion events are generated. If set, the manipulator will generate motion events beginning when the `OnMouseDown` method is called and ending when the `OnMouseUp` method is called. The default value is 0b (false).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TYPES

A string array specifying the visualization types that this manipulator can operate on. If not specified, the manipulator will support all registered visualization types.

Allowable TYPES values are those returned by the [IDLitVisualization::GetTypes](#) method.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

VIEWS_ONLY

A boolean value controlling the content of the manipulator hierarchy. If set, the manipulator will only operate on views in the manipulator hierarchy. The default value is 0b (false).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

VISUAL_TYPE

A string representing the type of selection visual to use with this manipulator. The VISUAL_TYPE property should match the corresponding property of an IDLitManipulatorVisual object. This high-level abstraction allows similar selection visuals to be assigned across multiple manipulators. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitManipulator::Cleanup

The IDLitManipulator::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitManipulator::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::CommitUndoValues

The IDLitManipulator::CommitUndoValues function method is used to complete a transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the RecordUndoValues method.

When a manipulator interaction is complete, the manipulator should call this method, which in turn calls the RecordFinalValues method of the operation associated with the manipulator. The RecordFinalValues method records any information needed to undo the operation and places the information in the iTool's undo-redo transaction buffer.

For interactive manipulators, the CommitUndoValues method should be called by the OnMouseUp method.

Note

This method must be called on the current manipulator before being called on a superclass to ensure that the current selection state maintained by the manipulator is valid.

Syntax

Result = *Obj*->[IDLitManipulator::]CommitUndoValues([/UNCOMMIT])

Return Value

Returns 1 if the commit was successful, or 0 otherwise.

Arguments

None

Keywords

UNCOMMIT

Set this keyword to discard any pending information from a previous call to RecordUndoValues. The interaction is not recorded in the iTool's undo-redo transaction buffer.

Version History

6.0	Introduced
-----	------------

IDLitManipulator::GetCursorType

The IDLitManipulator::GetCursorType function method retrieves the name of the cursor to display for the manipulator. The name of the cursor can be used with the SetCurrentCursor method of the IDLitWindow component.

The system will use this method to automatically change the cursor when the mouse traverses the contents of a visualization window. As the mouse transverses the window, the name for the hit item that is part of the current selection group is retrieved and passed to this routine. This action gives the manipulator the ability to change cursors depending on the area of the visualization the cursor is over.

Syntax

Result = *Obj*->[IDLitManipulator::]GetCursorType(*TypeIn*, *KeyMods*)

Return Value

Returns a string containing the name of the cursor. If nothing is matched, an empty string is returned.

Note

This name is defined during cursor registration using the [IDLitManipulator::RegisterCursor](#) method.

Arguments

TypIn

A string variable containing the name of the portion of the selection visual for which the cursor is being requested.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values

1 = SHIFT Key

2 = CTRL Key

4 = CAPS LOCK key

8 = ALT key

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::GetProperty

The IDLitManipulator::GetProperty procedure method retrieves the value of an IDLitManipulator property, and should be called by the subclass's GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

```
Obj->[IDLitManipulator::]GetProperty[, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under “[IDLitManipulator Properties](#)” on page 4816 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitManipulator::Init

The IDLitManipulator::Init function method initializes the IDLitManipulator object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitManipulator'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulator::]Init([, PROPERTY=value]) (In a lifecycle  
method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitManipulator Properties](#)” on page 4816 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitManipulator::OnKeyboard

The IDLitManipulator::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow.

Syntax

Obj->[IDLitManipulator:]OnKeyboard, *Win*, *IsASCII*, *Character*, *KeyValue*, *X*, *Y*,
Press, *Release*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow from which the event came.

IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

KeyValue

The numeric value representing the key pressed if the key is non-ASCII. The possible numeric values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

Character

A string containing the ASCII character of the key pressed.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::OnLoseCurrentManipulator

The IDLitManipulator::OnLoseCurrentManipulator procedure method is used when this manipulator is no longer the current manipulator in the system.

Note

This method is designed to be implemented by a subclass of IDLitManipulator, to perform any cleanup work necessary when a new manipulator is selected.

Syntax

Obj->[\[IDLitManipulator::\]](#)OnLoseCurrentManipulator

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::OnMouseDown

The `IDLitManipulator::OnMouseDown` procedure method is used when a mouse down event occurs on the target `IDLitWindow`. When applied, this method will perform a select operation on the current contents of the target `IDLitWindow`.

When overriding this method in a sub-class, this method is normally the first task performed so that the instance data of the object is properly setup.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- `ButtonPress` — Set to the mouse buttons pressed.
- `nSelectionList` — The number of items selected.
- `pSelectionList` — A pointer to the objects current selected in the `iTool`.

These values can be helpful in performing actions in the manipulator and are automatically managed. See “[Using Manipulator Public Instance Data](#)” (Chapter 8, *iTool Developer’s Guide*) for more information.

Syntax

Obj->[\[IDLitManipulator::\]OnMouseDown](#), *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

Arguments

Win

An object reference for the `IDLitWindow` from which the event came.

X

A floating-point value representing the *x*-coordinate in the window’s coordinates.

Y

A floating-point value representing the *y*-coordinate in the window’s coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

NClicks

An integer value representing number of clicks

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::OnMouseMotion

The IDLitManipulator::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down, this method manages the setting of the cursor on the IDLitWindow object.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.
- nSelectionList — The number of items selected.
- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed. See [“Using Manipulator Public Instance Data”](#) (Chapter 8, *iTool Developer’s Guide*) for more information.

Syntax

Obj->[IDLitManipulator::]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window’s coordinates.

Y

A floating-point value representing the *y*-coordinate in the window’s coordinates.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::OnMouseUp

The IDLitManipulator::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object.

When overriding this method in a sub-class, this method is normally the last task performed so that the instance data of the object is properly setup.

Syntax

Obj->[IDLitManipulator::]OnMouseUp, *Win, X, Y, IButton*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::OnWheel

The IDLitManipulator::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitManipulator, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitManipulator:]OnWheel, *Win*, *X*, *Y*, *Delta*, *Modifiers*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel towards the front of the mouse generates positive values, pulling the wheel towards the back of the mouse generates negative values. The magnitude of the value depends on the device setting for the individual mouse.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-7: Modifier Values

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLitManipulator::RecordUndoValues

The IDLitManipulator::RecordUndoValues function method is used to begin recording the transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the CommitUndoValues method.

To capture information for the undo-redo system of the tools framework, the initial and final values for the items that the manipulator will adjust must be recorded. This recording process is accomplished with the RecordUndoValues and CommitUndoValues methods.

These two methods make use of the operation that is associated with this manipulator (specified by the OPERATION_IDENTIFIER keyword to the Init method) to capture the needed information. When the RecordUndoValues method is called, the manipulator will retrieve the operation associated with this manipulator and call the RecordInitialValues method on this operation. The RecordInitialValues method is called with a command set, the list of currently selected items (which the manipulator is operating on) and the value that was provided by the PARAMETER_IDENTIFIER keyword to this manipulator. This method will record any information needed to undo the operation and place the values in the provided command set. See IDLitOperation for more information on operations.

For interactive manipulators, the RecordUndoValues method is called as part of the OnMouseDown method.

Syntax

Result = Obj->[IDLitManipulator::]RecordUndoValues()

Return Value

Returns a 1 if recording was successful, or 0 otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator::RegisterCursor

The IDLitManipulator::RegisterCursor procedure method defines the appearance and name of a cursor associated with the manipulator.

Syntax

Obj->[IDLitManipulator:]RegisterCursor, *ArrCursor*, *Name* [, /DEFAULT]

Return Value

None

Arguments

ArrCursor

This must be a 16 element string array of 16 characters each that represents a window cursor. The array can consist of the “#” character, space and non-space characters, and optionally, a “\$” character as follows:

- The “#” characters define the black outline of the cursor.
- Any non-space characters define the shape of the white mask. Adding a mask ensures the cursor’s visibility in light and dark areas of a visualization.
- The “\$” defines a hot spot.

See [CREATE_CURSOR](#) for more information on the structure of the cursor array.

Name

A string value identifying the cursor.

Note

This name should be returned by the [IDLitManipulator::GetCursorType](#) function method for your manipulator.

Keywords

DEFAULT

Set this keyword to specify this cursor as the default cursor for the manipulator. If no cursor is specified as the default cursor, then the standard arrow is used.

IDLitManipulator::SetCurrentManipulator

The IDLitManipulator::SetCurrentManipulator procedure method sets the manipulator as the current manipulator in the system.

Syntax

Obj->[IDLitManipulator::SetCurrentManipulator](#) [, *Item*]

Arguments

Item

If this method is being called on a manipulator container object, *Item* can optionally be set to a string containing the relative object ID of the manipulator that should be set as the current manipulator. If *Item* is not supplied, the manipulator on which the method is called is set as the current manipulator.

Keyword

None

Version History

6.0	Introduced
-----	------------

IDLitManipulator:: SetProperty

The IDLitManipulator::SetProperty procedure method sets the value of an IDLitManipulator property, and should be called by the subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitManipulator::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “IDLitManipulator Properties” on page 4816 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer

The IDLitManipulatorContainer class allows for the construction of manipulator hierarchies. Building on the functionality provided by the IDLitManipulator class, the manipulator container implements the concept of a *current manipulator* for the items it contains.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatorcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitContainer](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulatorContainer::Init](#)” on page 4853.

Properties

Objects of this class have the following properties. See “[IDLitManipulatorContainer Properties](#)” on page 4848 for details on individual properties.

- [AUTO_SWITCH](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLitManipulatorContainer::Add](#)
- [IDLitManipulatorContainer::GetCurrent](#)
- [IDLitManipulatorContainer::GetCurrentManipulator](#)
- [IDLitManipulatorContainer::GetProperty](#)

- [IDLitManipulatorContainer::Init](#)
- [IDLitManipulatorContainer::OnKeyboard](#)
- [IDLitManipulatorContainer::OnMouseDown](#)
- [IDLitManipulatorContainer::OnMouseMove](#)
- [IDLitManipulatorContainer::OnMouseUp](#)
- [IDLitManipulatorContainer::OnWheel](#)
- [IDLitManipulatorContainer::SetCurrent](#)
- [IDLitManipulatorContainer::SetCurrentManipulator](#)
- [IDLitManipulatorContainer::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Version History

6.0	Introduced
6.4	Added OnWheel method

IDLitManipulatorContainer Properties

IDLitManipulatorContainer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the table are retrieved via [IDLitManipulatorContainer::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table are set via [IDLitManipulatorContainer::Init](#). Properties with the word “Yes” in the “Set” column in the property table are set via [IDLitManipulatorContainer::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [AUTO_SWITCH](#)

In addition, objects of this class inherit:

- [IDLitContainer](#)

AUTO_SWITCH

A boolean that, if set, causes the manipulator container to automatically change the value of its current child manipulator depending on the portion of the selection visual hit during a mouse down operation. This is performed by matching the name of the portion of the selection visual hit during the mouse down operation and the name of the sub-manipulators of this container.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

IDLitManipulatorContainer::Add

The IDLitManipulatorContainer::Add procedure method is used to add a new manipulator to the container.

Syntax

Obj->[IDLitManipulatorContainer::]Add, *Manipulator*

Arguments

Manipulator

The new manipulator to add to this manipulator container. When completed, this manipulator is also set to the current manipulator for this manipulator container.

Keywords

All keywords are passed to the IDLitContainer superclass during the add operation.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::GetCurrent

The IDLitManipulatorContainer::GetCurrent function method is used to get the object reference of the current manipulator of the container.

Syntax

Result = *Obj*->[IDLitManipulatorContainer::]GetCurrent()

Return Value

Returns an object reference to the current manipulator for this container or a null object reference if no manipulators are contained by the container.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::GetCurrentManipulator

The IDLitManipulatorContainer::GetCurrentManipulator function method is used to get the current manipulator of the system. When applied, this function method causes a traversal of the manipulator hierarchy, returning the current leaf manipulator of the system.

Syntax

```
Result =  
Obj->[IDLitManipulatorContainer::]GetCurrentManipulator([, /IDENTIFIER])
```

Return Value

Returns an object reference to the current manipulator in the system. If the IDENTIFIER keyword is set, the routine will return the identifier for the current manipulator.

Arguments

None

Keywords

IDENTIFIER

If set, the identifier of the current manipulator is returned. If not set, the current manipulator itself is returned.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::GetProperty

The IDLitManipulatorContainer::GetProperty procedure method retrieves the value of an IDLitManipulatorContainer property, and should be called by the subclass's GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitManipulatorContainer::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 4848 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::Init

The `IDLitManipulatorContainer::Init` function method initializes the `IDLitManipulatorContainer` object, and should be called by the subclass's `Init` method. This method also calls the superclass's `Init` method.

Note

`Init` methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the `Init` method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the `Init` method from within the `Init` method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitManipulatorContainer'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulatorContainer::]Init( [, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the `OBJ_NEW` function, the return value is an object reference to the newly-created object.

When called directly within a subclass `Init` method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 4848 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::OnKeyboard

The IDLitManipulatorContainer::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow object. If the current child manipulator supports keyboard events, the OnKeyboard method for that manipulator is called.

Syntax

Obj->[IDLitManipulatorContainer::]OnKeyboard, *Win*, *IsASCII*, *Character*, *KeyValue*, *X*, *Y*, *Press*, *Release*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

KeyValue

The numeric value representing a non-ASCII key pressed. The possible values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

Character

A string containing the ASCII character of the key pressed

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::OnMouseDown

The `IDLitManipulatorContainer::OnMouseDown` procedure method is used when a mouse down event occurs on the target `IDLitWindow` object. When applied and auto-switch mode is enabled in the container, the current child manipulator will be determined by matching the type of the visualization hit with the identifier of the sub-manipulators contained in this container. If no match is made, the default child manipulator is selected. Once complete, normal processing continues.

If the current sub-manipulator supports mouse button events, its `OnMouseDown` method is called.

Syntax

Obj->[IDLitManipulatorContainer::]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

Arguments

Win

An object reference for the `IDLitWindow` object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

NClicks

An integer value representing number of clicks

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::OnMouseMotion

The IDLitManipulatorContainer::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down and auto-switch mode is enabled, this method manages the setting of the cursor on the IDLitWindow object. Otherwise if the current sub-manipulator supports motion events, its OnMouseMotion method is called.

Syntax

Obj->[IDLitManipulatorContainer:]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::OnMouseUp

The IDLitManipulatorContainer::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object. When applied, the container will call the OnMouseUp method of the current child manipulator if that manipulator supports button events.

Syntax

Obj->[IDLitManipulatorContainer::]OnMouseUp, *Win*, *X*, *Y*, *IButton*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A floating-point value representing the *x*-coordinate in the window's coordinates.

Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::OnWheel

The IDLitManipulatorContainer::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred.

Note

This method is only useful in conjunction with the Export Bridge. The method is only a stub and provides no functionality. In your subclass of IDLitManipulatorContainer, you should override this method to provide your own functionality. Your method will be automatically called by the Export Bridge. For more information, see [“Exporting Drawable Objects”](#) (Chapter 11, *IDL Connectivity Bridges*).

Syntax

Obj->[IDLitManipulatorContainer::]OnWheel, *Win, X, Y, Delta, Modifiers*

Arguments

Win

An object reference for the IDLitWindow object from which the event came.

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel towards the front of the mouse generates positive values, pulling the wheel towards the back of the mouse generates negative values. The magnitude of the value depends on the device setting for the individual mouse.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-8: Modifier Values

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLitManipulatorContainer::SetCurrent

The IDLitManipulatorContainer::SetCurrent procedure method is used to set a manipulator within the container to be the current manipulator.

Syntax

Obj->[IDLitManipulatorContainer::SetCurrent](#), *Manipulator*

Arguments

Manipulator

The object reference of the manipulator to be set as current in the manipulator container. This manipulator must be contained in the container or an error is thrown.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer::SetCurrentManipulator

The IDLitManipulatorContainer::SetCurrentManipulator procedure method is used to set the current child manipulator in a manipulator hierarchy. When applied, the manipulator will use the provided identifier to call the SetCurrentManipulator on the target child manipulator. If the provided identifier is null, the default manipulator is set as current.

Syntax

Obj->[IDLitManipulatorContainer::]SetCurrentManipulator, *Identifier*

Arguments

Identifier

Either the identifier for the manipulator that is to be made current in the system or its object reference.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorContainer:: SetProperty

The IDLitManipulatorContainer::SetProperty procedure method sets the value of an IDLitManipulatorContainer property, and should be called by the subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitManipulatorContainer::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorContainer Properties](#)” on page 4848 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorManager

The IDLitManipulatorManager class is a specialization of a IDLitManipulatorContainer class that acts as the root of a manipulator hierarchy. In addition, this class provides the functionality that allows it to interface with external elements in the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatormanager__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitManipulatorContainer](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulatorManager::Init](#)” on page 4873.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitManipulatorManager::Add](#)
- [IDLitManipulatorManager::AddManipulatorObserver](#)
- [IDLitManipulatorManager::GetDefaultManipulator](#)
- [IDLitManipulatorManager::Init](#)
- [IDLitManipulatorManager::RemoveManipulatorObserver](#)

In addition, this class inherits the methods of its superclass.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorManager Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclass.

Objects in this class inherit:

- [IDLitManipulatorContainer](#)

IDLitManipulatorManager::Add

The IDLitManipulatorManager::Add procedure method is used to add manipulators to the manipulator manager. This method uses the add functionality of its superclass to add the given manipulator to the hierarchy and checks the default keyword to determine if the given manipulator should be treated as the default for the system.

Syntax

Obj->[IDLitManipulatorManager::]Add, *Manipulator* [, /DEFAULT]

Arguments

Manipulator

A manipulator to add to the manipulator manager

Keywords

DEFAULT

If set, the added manipulator is made default for the system. This is primarily used with manipulators that implement transient behavior (mouse or keyboard). When these manipulators complete interaction, the current manipulator of the system is set to the default manipulator.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorManager::AddManipulatorObserver

The `IDLitManipulatorManager::AddManipulatorObserver` procedure method is used to add an observer to the manipulator system. An observer object is notified when the current manipulator of the manipulator hierarchy changes.

To perform this action, the observer object must implement the method `OnManipulatorChange`. This method has the following signature:

```
PRO ObjectClass::OnManipulatorChange, Subject
```

Where *Subject* is this class, the manipulator manager.

Syntax

```
Obj->[IDLitManipulatorManager:]AddManipulatorObserver, Observer
```

Arguments

Observer

A scalar or array of objects that implement the manipulator observer interface.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorManager::GetDefaultManipulator

The IDLitManipulatorManager::GetDefaultManipulator function method returns a reference to the manipulator that was most recently added as the default manipulator. The return value is a reference to an IDLitManipulator object, or the NULL object reference if no manipulators have been added as a default.

Syntax

Result = *Obj*->[IDLitManipulatorManager::]GetDefaultManipulator()

Keywords

None

Arguments

None

Version History

6.1	Introduced
-----	------------

IDLitManipulatorManager::Init

The IDLitManipulatorManager::Init function method initializes the IDLitManipulatorManager object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitManipulatorManager' [, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulatorManager::]Init([PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorManager Properties](#)” on page 4869 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorManager::RemoveManipulatorObserver

The `IDLitManipulatorManager::RemoveManipulatorObserver` procedure method is used to remove a manipulator observer from the manipulator object. If the value for the *Observer* argument is not a valid manipulator observer, this method does nothing and no error is reported.

Syntax

Obj->[IDLitManipulatorManager::]RemoveManipulatorObserver, *Observer*

Arguments

Observer

A scalar or array of objects that are to be removed from this container

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorVisual

The IDLitManipulatorVisual class implements methods that allow the iTool developer to create visual elements that are associated with an interactive manipulator. IDLitManipulatorVisual objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Superclasses

[IDLgrModel](#)

[IDLitMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitManipulatorVisual::Init](#)” on page 4882.

Properties

Objects of this class have the following properties. See “[IDLitManipulatorVisual Properties](#)” on page 4878 for details on individual properties.

- [UNIFORM_SCALE](#)
- [VISUAL_TYPE](#)

Methods

This class has the following methods:

- [IDLitManipulatorVisual::Cleanup](#)
- [IDLitManipulatorVisual::GetProperty](#)
- [IDLitManipulatorVisual::Init](#)
- [IDLitManipulatorVisual::SetProperty](#)

Version History

6.0	Introduced
-----	------------

IDLitManipulatorVisual Properties

IDLitManipulatorVisual objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitManipulatorVisual::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitManipulatorVisual::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitManipulatorVisual::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [UNIFORM_SCALE](#)
- [VISUAL_TYPE](#)

In addition, objects of this class inherit:

- [IDLgrModel](#)
- [IDLitIMessaging](#)

UNIFORM_SCALE

Set this property to create a manipulator visual which should be scaled equally in all three dimensions when fitting the manipulator visual to the size of its associated visualization. If this property is not set, then the manipulator visual will use a different scale factor in the *x*, *y*, and *z* dimensions, in order to match its associated visualization.

Property Type	Boolean		
Name String	<i>not applicable</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VISUAL_TYPE

Set this keyword to a string representing the manipulator visual type. The `VISUAL_TYPE` property should match the corresponding string in its associated IDLitManipulator object. When a new manipulator is selected in an iTool, the

VISUAL_TYPE property on the manipulator object is used to search for a corresponding manipulator visual.

Property Type	String		
Name String	<i>not applicable</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitManipulatorVisual::Cleanup

The IDLitManipulatorVisual::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitManipulatorVisual::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitManipulatorVisual::GetProperty

The IDLitManipulatorVisual::GetProperty procedure method retrieves the value of an IDLitManipulatorVisual property.

Syntax

Obj->[\[IDLitManipulatorVisual::\]](#)GetProperty

Arguments

None

Keywords

Any property listed under [“IDLitManipulatorVisual Properties”](#) on page 4878 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorVisual::Init

The IDLitManipulatorVisual::Init function method initializes the IDLitManipulatorVisual object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitManipulatorVisual'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitManipulatorVisual::]Init([, PROPERTY=value]) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “IDLitManipulatorVisual Properties” on page 4878 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitManipulatorVisual:: SetProperty

The IDLitManipulatorVisual::SetProperty procedure method sets the value of an IDLitManipulatorVisual property.

Syntax

Obj->[IDLitManipulatorVisual::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitManipulatorVisual Properties](#)” on page 4878 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitOperation

The IDLitOperation class is the basis for all iTool operations. It defines how an operation is executed and how information about the operation is recorded for the command transaction (undo-redo) system.

An operation encapsulates a specific set of tasks that perform some atomic action on a target. Between executions of the operation, no state values other than properties of the operation itself are maintained by this object. Two major areas of functionality are provided: automated operation execution and undo-redo capabilities.

Once defined, the operation object exposes a set of properties whose values can affect how the operation executes. The properties that an operation exposes are valid across multiple executions; properties can be set interactively via the Operation browser or programmatically using the operation object's GetProperty and SetProperty methods.

Note

For operations that act directly on data items that underlie a visualization, consider basing your operation class on the IDLitDataOperation class. IDLitDataOperation is a subclass of IDLitOperation that automates many of the target-selection and undo-redo mechanisms that must be provided by operation classes based directly on this class.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see [Chapter 7, “Creating an Operation”](#) (*iTool Developer's Guide*).

This class is written in the IDL language. Its source code can be found in the file `idlitoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitOperation::Init](#)” on page 4894.

Properties

Objects of this class have the following properties. See “[IDLitOperation Properties](#)” on page 4888 for details on individual properties.

- [EXPENSIVE_COMPUTATION](#)
- [REVERSIBLE_OPERATION](#)
- [SHOW_EXECUTION_UI](#)
- [TYPES](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Note

By default, for `IDLitOperation` and its subclasses, the `NAME` property is hidden and the `DESCRIPTION` property is desensitized. This prevents a user from changing the name of an operation via the property sheet, which could change the name of a menu item. If you wish to expose these properties for your own subclass of `IDLitOperation`, you will need to unhide and sensitize the `NAME` and `DESCRIPTION` properties in your `Init` method.

Methods

This class has the following methods:

- [IDLitOperation::Cleanup](#)
- [IDLitOperation::DoAction](#)
- [IDLitOperation::GetProperty](#)
- [IDLitOperation::Init](#)
- [IDLitOperation::QueryAvailability](#)
- [IDLitOperation::RecordFinalValues](#)
- [IDLitOperation::RecordInitialValues](#)
- [IDLitOperation::RedoOperation](#)
- [IDLitOperation::SetProperty](#)

- [IDLitOperation::UndoOperation](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.2	Added QueryAvailability method

See Also

[IDLitDataOperation](#)

IDLitOperation Properties

IDLitOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via [IDLitOperation::GetProperty](#). Properties with the word “Yes” in the “Init” column of the properties table can be initialized via [IDLitOperation::Init](#). Properties with the word “Yes” in the “Set” column of the properties table can be set via [IDLitOperation::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [EXPENSIVE_COMPUTATION](#)
- [REVERSIBLE_OPERATION](#)
- [SHOW_EXECUTION_UI](#)
- [TYPES](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)
- [IDLitMessaging](#)

EXPENSIVE_COMPUTATION

Set this property to 1 to indicate that a computation of the operation is *expensive*. Expensive computations are those that require significant memory or processing time to execute. Individual operations should use the value of this property to determine whether the results of the operation should be cached to avoid re-execution when undoing or redoing.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

REVERSIBLE_OPERATION

Set this property to 1 to indicate that the operation is *reversible*. When an operation is reversible, it can be undone by applying an operation rather than restoring a stored value. Rotation by a specified angle is an example of an operation that is reversible, since applying another rotation by the complementary angle returns the visualization to its original state. Individual operations should use the value of this property to determine how the operation should be undone.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

SHOW_EXECUTION_UI

Set this property to 1 to indicate that the operation should display a user interface element such as a dialog when the operation is executed. The flag is ignored by the IDLiteOperation itself, but can be used by subclasses (notably IDLiteDataOperation) to determine when to display user interface elements. This property is registered, but it is hidden by default.

Property Type	Boolean		
Name String	Show Dialog		
Get: Yes	Set: No	Init: Yes	Registered: Yes

TYPES

Set this property to a string or an array of strings indicating the data or visualization types to which the operation can be applied. iTools data types are described in [Chapter 3, “Data Management”](#) (*iTool Developer’s Guide*); iTools visualization types are described in [Chapter 6, “Creating a Visualization”](#) (*iTool Developer’s Guide*). Set this property to a null string (' ') to specify that the operation can be applied to data and visualizations of all types.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLitOperation::Cleanup

The IDLitOperation::Cleanup procedure method performs all cleanup on the object.

Note

An operation based on the IDLitOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitOperation::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitOperation::DoAction

The `IDLitOperation::DoAction` function method is called when an operation is requested by the iTools system, either as the result of a user action such as selection of a menu item or toolbar button, or by another operation.

Note

Every operation based directly on the `IDLitOperation` class must implement its own `DoAction` method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

A specific operation class’ implementation of this method must create an initialized `IDLitCommandSet` object, execute the operation, and return the command set object to the caller. `DoAction` can also call the [IDLitOperation::RecordInitialValues](#) and [IDLitOperation::RecordFinalValues](#) methods to ensure that the appropriate values are committed to the undo-redo transaction buffer.

If your operation changes the values of its own registered properties (as the result of user interaction with a dialog or other interface element called by `DoUIService`, for example), be sure to call the `RecordInitialValues` and `RecordFinalValues` methods. This ensures that changes made through the dialog are placed in the undo-redo transaction buffer.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo/Redo mechanism.

Syntax

```
Result = Obj->[IDLitOperation::]DoAction(Tool)
```

Return Value

If successful, this method returns an `IDLitCommandSet` object or array of `IDLitCommandSet` objects that will be placed in the iTool’s command buffer. The command set object will be passed to the `UndoOperation` and `RedoOperation` methods as necessary. If not successful, this method returns a null object reference.

Note

The `OPERATION_IDENTIFIER` property of the command set object returned by the `IDLitOperation::DoAction` method is set equal to the full identifier of the operation itself. This implies that `UndoOperation` and `RedoOperation` methods exist for the operation, and that they implement the necessary undo and redo mechanisms. If you are overriding this method, you must either ensure that the appropriate `UndoOperation` and `RedoOperation` methods exist, or manually create an `IDLitCommandSet` object with the `OPERATION_IDENTIFIER` set to another operation that is capable of undoing or redoing the changes made by your method.

Arguments

Tool

An object reference to the `iTool` object on which the operation executes.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitOperation::GetProperty

The IDLitOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

Note

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Syntax

```
Obj->[IDLitOperation:]GetProperty [, PROPERTY=variable]
```

Arguments

None

Keywords

Any property listed under “[IDLitOperation Properties](#)” on page 4888 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj->IDLitOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

Version History

6.0	Introduced
-----	------------

IDLitOperation::Init

The IDLitOperation::Init function method initializes the IDLitOperation object and sets properties that define the behavior the operation provides.

Note

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitOperation' [, PROPERTY=variable] )
```

or

```
Result = Obj->[IDLitOperation::]Init( [, PROPERTY=variable] ) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitOperation Properties”](#) on page 4888 that contains the word “Yes” in the “Init” column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitOperation::QueryAvailability

The `IDLitOperation::QueryAvailability` function method is automatically called by the iTool to determine whether this operation is applicable for the selected data and/or visualization. By default, whenever selection changes in the tool, the operation is queried to determine if its type matches the type of the visualization or the data within the visualization. The menu item or toolbar button associated with the operation is then enabled or disabled automatically.

If you are writing a subclass of `IDLitOperation` and you do not want to use the standard type matching, you might want to override this method in your own subclass.

Syntax

```
Result = Obj->[IDLitOperation::]QueryAvailability( Tool, SelTypes )
```

Return Value

This method returns a 1 if the object is applicable for the selected items, or 0 (zero) otherwise.

Arguments

Tool

An object reference to the iTool object on which the operation executes.

SelTypes

A string array containing the types of the currently selected visualizations. For an explanation of iTool types, see “[Predefined iTool Visualization Classes](#)” (Chapter 6, *iTool Developer’s Guide*).

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLitOperation::RecordFinalValues

The `IDLitOperation::RecordFinalValues` function method records the information needed to redo an operation. Information about individual operations is recorded in `IDLitCommand` objects, which are in turn stored in an `IDLitCommandSet` object that is passed to the [IDLitOperation::UndoOperation](#) and [IDLitOperation::RedoOperation](#) methods.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the appropriate `IDLitCommand` object from the `IDLitCommandSet` object specified as the first parameter,
- Record any information necessary to redo the operation in the `IDLitCommand` object,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]RecordFinalValues(CommandSet, Targets  
[, IdProperty])
```

Return Value

The return value is 1 if the final values were recorded successfully, or zero otherwise.

Arguments

CommandSet

An `IDLitCommandSet` object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the [IDLitOperation::DoAction](#) method, which then calls the `RecordInitialValues` method to store the initial state of the target object.

Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the [IDLitTool::GetSelectedItems](#) method.

IdProperty

A property identifier string specifying the target property or parameter of the operation.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitOperation::RecordInitialValues

The `IDLitOperation::RecordInitialValues` function method records the information needed to undo an operation. Information about individual operations is recorded in `IDLitCommand` objects, which are in turn stored in an `IDLitCommandSet` object that is passed to the [IDLitOperation::UndoOperation](#) and [IDLitOperation::RedoOperation](#) methods.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the `IDLitOperation` class. `IDLitDataOperation` provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Create an `IDLitCommand` object, setting its `TARGET_IDENTIFIER` property to the identifier of the target object
- Record any information necessary to redo the operation in the `IDLitCommand` object
- Add the `IDLitCommand` object to the `IDLitCommandSet` object specified as the first parameter
- Return 1 for success

Syntax

```
Result = Obj->[IDLitOperation::]RecordInitialValues(CommandSet, Targets  
[, IdProperty])
```

Return Value

The return value is 1 if the initial values were recorded successfully, or zero otherwise.

Arguments

CommandSet

An `IDLitCommandSet` object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the

[IDLitOperation::DoAction](#) method, which then calls the `RecordInitialValues` method to store the initial state of the target object.

Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the [IDLitTool::GetSelectedItems](#) method.

IdProperty

A property identifier string specifying the target property or parameter of the operation.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitOperation::RedoOperation

The IDLitOperation::RedoOperation function method is called by the iTool system when the user requests the re-execution of an operation (usually by selecting Redo from the iTool Edit menu or toolbar).

Note

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,
- For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,
- Retrieve the stored information and use it to redo the operation,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]RedoOperation(CommandSet)
```

Return Value

The return value is 1 if the operation was redone successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

Keywords

None

Version History

6.0	Introduced
-----	------------

See Also

[IDLitOperation::RecordFinalValues](#), [IDLitOperation::RecordInitialValues](#),
[IDLitOperation::UndoOperation](#)

IDLitOperation:: SetProperty

The IDLitOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

Note

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Syntax

Obj->[IDLitOperation::]SetProperty [, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitOperation Properties](#)” on page 4888 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitOperation::UndoOperation

The IDLitOperation::UndoOperation function method is called by the iTool system when the user requests the un-execution of an operation (usually by selecting Undo from the iTool Edit menu or toolbar).

Note

An operation based on the IDLitOperation class *must* implement this method. See [Chapter 7, “Creating an Operation”](#) (*iTool Developer’s Guide*) for details.

Note

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the [IDLitDataOperation](#) class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,
- For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,
- Retrieve the stored information and use it to undo the operation,
- Return 1 for success.

Syntax

```
Result = Obj->[IDLitOperation::]UndoOperation(CommandSet)
```

Return Value

The return value is 1 if the operation was undone successfully, or zero otherwise.

Arguments

CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameter

The IDLitParameter class implements parameter management methods that allow parameter names to be associated with IDLitData objects. IDLitParameter objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

Note

In the iTools system, management of data parameters is handled by the IDLitVisualization class, of which the IDLitParameter class is a superclass. In practice, this means that if you need to override any methods of the IDLitParameter class, you will do so in the definition of your visualization class. In most cases, the only method you will need to implement is the OnDataChangeUpdate method.

When an object that inherits from the IDLitParameter class is created, the following are created as part of the new object's instance data:

- An IDL_Container object, which will contain parameter names for all parameters registered with the object. Parameter names are discussed in [“Parameters”](#) (Chapter 3, *iTool Developer's Guide*),
- A pointer to a string array containing the parameter names for all parameters registered with the object,
- An IDLitParameterSet object, which will contain the actual IDLitData objects associated with the object's parameters. Parameter sets are discussed in [“Parameter Sets”](#) (Chapter 3, *iTool Developer's Guide*), and in [“IDLitParameterSet”](#) on page 4930.

This class is written in the IDL language. Its source code can be found in the file `idlitparameter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

None

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

The objects of this class are not created as standalone objects.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDLitParameter::Cleanup](#)
- [IDLitParameter::GetParameter](#)
- [IDLitParameter::GetParameterAttribute](#)
- [IDLitParameter::GetParameterSet](#)
- [IDLitParameter::Init](#)
- [IDLitParameter::OnDataChangeUpdate](#)
- [IDLitParameter::OnDataDisconnect](#)
- [IDLitParameter::QueryParameter](#)
- [IDLitParameter::RegisterParameter](#)
- [IDLitParameter::SetData](#)
- [IDLitParameter::SetParameterAttribute](#)
- [IDLitParameter::SetParameterSet](#)

Version History

6.0	Introduced
-----	------------

IDLitParameter Properties

Objects of this class have no properties of their own.

IDLitParameter::Cleanup

The IDLitParameter::Cleanup procedure method removes the *data observer* from each data object in the visualization object's parameter set, and cleans up the objects and pointers defined to hold parameter data when the visualization object was created.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitParameter::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameter::GetParameter

The IDLitParameter::GetParameter function method retrieves the IDLitData object associated with a registered parameter.

Syntax

```
Result = Obj->[IDLitParameter::]GetParameter(Name [, /ALL]  
[, COUNT=variable])
```

Return Value

Returns an object reference to the IDLitData object associated with the specified parameter name, or a null object reference if no data objects are associated with the specified parameter name.

Arguments

Name

A scalar string containing the parameter name associated with the IDLitData object to be retrieved.

Keywords

ALL

Set this keyword to retrieve all of the IDLitData objects contained in the visualization object's IDLitParameterSet object.

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

Version History

6.0	Introduced
-----	------------

IDLitParameter::GetParameterAttribute

The IDLitParameter::GetParameterAttribute procedure method retrieves one or more parameter attributes for a registered parameter.

Syntax

```
Obj->[IDLitParameter:]GetParameterAttribute, ParamName  
    [, BY_VALUE=variable] [, DESCRIPTION=variable] [, INPUT=variable]  
    [, OPTARGET=variable] [, OPTIONAL=variable] [, OUTPUT=variable]  
    [, TYPES=variable]
```

Arguments

ParamName

A scalar string or string array containing names of registered parameters.

Keywords

BY_VALUE

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is marked as being a by-value parameter, or a 0 (zero) if *ParamName* is marked as being a by-reference parameter.

DESCRIPTION

Set this keyword equal to a named variable that will contain the full name or description of this object.

INPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an input parameter, or a 0 (zero) otherwise.

OPTARGET

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* may be the target of any operations, or a 0 (zero) otherwise.

OPTIONAL

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an optional parameter, or a 0 (zero) otherwise.

OUTPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an output parameter, or a 0 (zero) otherwise.

TYPES

Set this keyword equal to a named variable that will contain a scalar string or string array giving the data types that correspond to this parameter. See “[iTool Data Types](#)” (Chapter 3, *iTool Developer’s Guide*) for more on parameter data types.

Example

This example creates an *iPlot* tool and retrieves the description attribute of the registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = IGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc
```

IDL prints:

```
Vertex Data
```

Version History

6.1	Introduced
-----	------------

See Also

[IDLitParameter::QueryParameter](#), [IDLitParameter::RegisterParameter](#),
[IDLitParameter::SetParameterAttribute](#)

IDLitParameter::GetParameterSet

The IDLitParameter::GetParameterSet function method returns a reference to the IDLitParameterSet object associated with the visualization object.

Syntax

Result = *Obj*->[IDLitParameter::]GetParameterSet([/DEEP_COPY])

Return Value

Returns an IDLitParameterSet object that contains the IDLitData objects and associated parameter names for the visualization object.

Arguments

None

Keywords

DEEP_COPY

Set this keyword to cause GetParameterSet to return a parameter set that contains *copies* of the IDLitData objects used by the visualization object's registered parameters. If this keyword is not set, the parameter set returned by this function will contain *references* to the IDLitData objects that are being used by the visualization object's registered parameters.

Version History

6.0	Introduced
-----	------------

IDLitParameter::Init

The IDLitParameter::Init function method initializes object instance fields that contain parameter data. Since the IDLitParameter class is always used as a superclass of another class (IDLitVisualization, in the context of the iTool system), initializing this class simply initializes the objects and pointers used to store parameter information in the IDLitVisualization object.

Note

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Result = *Obj*->[IDLitParameter::]Init() (In a lifecycle method only.)

Return Value

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameter::OnDataChangeUpdate

The IDLitParameter::OnDataChangeUpdate method is called when a data value has been updated or a new data object has been associated with the visualization object.

Note

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

Syntax

Obj->[IDLitParameter:]OnDataChangeUpdate, *Data*, *ParameterName*

Arguments

Data

An object reference to the IDLitData object or the IDLitParameterSet object containing the changed parameter data. If *Data* is an IDLitParameterSet object, the *ParameterName* argument must be set to the string '<PARAMETER SET>'.

ParameterName

An upper-case scalar string containing the name of the parameter that has changed. The parameter specified via this argument must be registered with the visualization object. If *oData* is an IDLitParameterSet object, this argument must be set to the string '<PARAMETER SET>'.

Keywords

None

Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following code handles a parameter named z:

```

PRO MyVis::OnChangeUpdate, oData, ParameterName

CASE ParameterName OF
  'Z': BEGIN
    ;; do something with the z data
  END
  '<PARAMETER SET>': BEGIN
    oZ = oData->GetByName('Z')
    ;; do something with the z data.
  END
ENDCASE

END

```

Note

The Z parameter is handled twice — once if supplied as an individual IDLitData object and once if supplied via the IDLitParameterSet object.

See “[Creating an OnDataChangeUpdate Method](#)” in the section “[Creating a New Visualization Type](#)” (Chapter 6, *iTool Developer’s Guide*) for more discussion of the OnDataChangeUpdate method.

Version History

6.0	Introduced
-----	------------

IDLitParameter::OnDataDisconnect

The IDLitParameter::OnDataDisconnect procedure method is called when a data value has been disconnected from a parameter. The general idea is that when a data item is disassociated from a visualization parameter, one or more properties of the visualization may need to be reset to reasonable default values.

Note

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

Syntax

Obj->[IDLitParameter:]OnDataDisconnect, *ParameterName*

Arguments

ParameterName

An upper-case string containing the name of the parameter that was disconnected. The parameter must have been previously registered with the visualization.

Keywords

None

Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following sample code performs some action when the parameter name is TEXTURE:

```
PRO MyVis::OnDataDisconnect, ParameterName

CASE ParameterName OF
  'TEXTURE': BEGIN
    ;; do something to remove the ref. of the texture
  END
ENDCASE

END
```

Version History

6.0	Introduced
-----	------------

IDLitParameter::QueryParameter

The IDLitParameter::QueryParameter function method checks whether a parameter is registered, or retrieves a list of the names of all registered parameters.

Syntax

```
Result = Obj->[IDLitParameter::]QueryParameter([ParamName]
[, COUNT=variable])
```

Return Value

If *ParamName* is a scalar string, this function returns a 1 if *ParamName* corresponds to a valid registered parameter, or a 0 otherwise. If *ParamName* is an array, the result is an array of 1s and 0s. If *ParamName* is not specified, *Result* is a string array containing the names of all registered parameters.

Arguments

ParamName

A scalar string or string array containing parameter names. If *ParamName* is not supplied, this function returns a list of all registered parameters.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of parameters in *Result*. If *ParamName* is not supplied, then COUNT contains the number of registered parameters. If *ParamName* is supplied then COUNT contains the total number of matched parameters.

Example

This example creates an iPlot tool and tests whether a the plot visualization has a registered parameter named “vertices”:

```
IPLOT, RANDOMU(seed, 15)
idTool = IGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
PRINT, oPlot->QueryParameter('vertices')
```

IDL prints:

```
1
```

Continuing the same example, we now query for the names of all parameters of the plot visualization:

```
Params = oPlot->QueryParameter(COUNT=count)
FOR i=0,count-1 DO PRINT, Params[i]
```

IDL prints:

```
Y
X
VERTICES
Y ERROR
X ERROR
PALETTE
VERTEX_COLORS
```

Version History

6.1	Introduced
-----	------------

See Also

[IDLitParameter::GetParameter](#), [IDLitParameter::GetParameterAttribute](#),
[IDLitParameter::RegisterParameter](#), [IDLitParameter::SetParameterAttribute](#)

IDLitParameter::RegisterParameter

The IDLitParameter::RegisterParameter procedure method registers a parameter with the visualization object. Registered parameters are displayed in the iTool parameter editor dialog, allowing users to interactively assign data values to individual visualization parameters.

Syntax

```
Obj->[IDLitParameter::]RegisterParameter, Name [, /BY_VALUE]  
    [, DESCRIPTION=string] [, /INPUT] [, /OPTARGET] [, /OPTIONAL]  
    [, /OUTPUT] [, TYPES=string]
```

Arguments

Name

Set this argument to a string specifying the name of the parameter.

Keywords

BY_VALUE

Set this keyword to indicate that this parameter is a by-value parameter. If a parameter is marked as by value, when data is associated with it a copy of the data is made and managed by this class.

DESCRIPTION

Set this keyword to a string giving the full name or description of this object.

INPUT

Set this keyword to indicate that this is an input parameter.

OPTARGET

Set this keyword to indicate that this parameter may be the target of any operations.

OPTIONAL

If this keyword is set, then this parameter is an optional parameter, and it is not required to be set. The default is `OPTIONAL=0`, indicating that it is required to be set.

OUTPUT

Set this keyword to indicate that this is an output parameter.

TYPES

Set this keyword to a scalar string or string array giving the data types that correspond to this parameter. See [“iTool Data Types”](#) (Chapter 3, *iTool Developer’s Guide*) for more on parameter data types.

Version History

6.0	Introduced
-----	------------

IDLitParameter::SetData

The IDLitParameter::SetData function method is used to set data in this interface, associating a data object with a given parameter. This method can automatically perform type matching to determine which parameter to associate with a particular parameter or the user can specify a parameter name.

If a parameter name is provided by the user via the PARAMETER_NAME keyword, this method will query the given data object for a data item that is of one of the types supported by this parameter and associate the found data item with the parameter. This could be the data object provided or if the data object contains other data objects, one of its children. If a type match doesn't occur, the method will return 0.

If no parameter name is provided, this method will start with the first available parameter (non-associated parameters, starting with op-targets first) and attempt to perform a data type match. When a data type match between the parameter and the provided data item (or one of its contained items) the association between the two are made.

When a data match has been made, this object is made an observer of the data object and if the NO_UPDATE keyword is not set, the onDataChangeUpdate() method is called on this object.

If a type match is found, but the given parameter already has a data object associated with it, the type match will continue.

If a match cannot be found, a value of 0 is returned.

Syntax

```
Result = Obj->[IDLitParameter::]SetData(Data [, /BY_VALUE] [, /NO_UPDATE]
    [, PARAMETER_NAME=string] )
```

Return Value

Returns 1 if the IDLitData object was successfully matched with a parameter registered with the visualization object, or 0 otherwise.

Arguments

Data

An IDLitData object to be matched with a parameter registered with the visualization object.

Keywords

BY_VALUE

Set this keyword to cause *Data* to be copied and managed by the visualization's parameter interface. If this keyword is not set, the data object is managed by the iTool system, and can be altered by other iTools.

NO_UPDATE

Set this keyword to prevent the `OnDataChangeUpdate` method from being called when *Data* is associated with one of the visualization object's registered parameters. If this keyword is not set, the `OnDataChangeUpdate` method is called, providing the opportunity for subclasses of the visualization object to be notified that data associated with the parameter interface has changed.

PARAMETER_NAME

Set this keyword to a scalar string containing the name of the registered parameter with which *Data* should be associated. If the iTool data type of the data contained in *Data* does not match one of the data types supported by the specified registered parameter, *Data* will not be associated with the registered parameter and this function will return zero.

Version History

6.0	Introduced
-----	------------

IDLitParameter::SetParameterAttribute

The IDLitParameter::SetParameterAttribute procedure method sets one or more parameter attributes for a registered parameter.

Syntax

```
Obj->IDLitParameter::SetParameterAttribute, ParamName  
    [, /BY_VALUE=variable] [, /DESCRIPTION=variable] [, /INPUT=variable]  
    [, /OPTARGET=variable] [, /OPTIONAL=variable] [, /OUTPUT=variable]  
    [, /TYPES=variable]
```

Arguments

ParamName

A scalar string or string array containing names of registered parameters. If *ParamName* is an array, the specified attribute values are set on all parameters in the array.

Keywords

BY_VALUE

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is marked as being a by-value parameter, or a 0 (zero) if *ParamName* is marked as being a by-reference parameter.

DESCRIPTION

Set this keyword equal to a named variable that will contain the full name or description of this object.

INPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an input parameter, or a 0 (zero) otherwise.

OPTARGET

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* may be the target of any operations, or a 0 (zero) otherwise.

OPTIONAL

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an optional parameter, or a 0 (zero) otherwise.

OUTPUT

Set this keyword equal to a named variable that will contain a 1 (one) if *ParamName* is an output parameter, or a 0 (zero) otherwise.

TYPES

Set this keyword equal to a named variable that will contain a scalar string or string array giving the data types that correspond to this parameter. See “[iTool Data Types](#)” (Chapter 3, *iTool Developer’s Guide*) for more on parameter data types.

Example

This example creates an *iPlot* tool sets the description attribute of the registered parameter named “vertices”:

```

IPLOT, RANDOMU(seed, 15)
idTool = IGETCURRENT(TOOL=otool)
idPlot = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)
oPlot = oTool->GetByIdentifier(idPlot)
oPlot->SetParameterAttribute, 'vertices', $
    DESCRIPTION='My Vertex Data'
oPlot->GetParameterAttribute, 'vertices', DESCRIPTION=desc
PRINT, desc

```

IDL prints:

```
My Vertex Data
```

Version History

[IDLitParameter::RegisterParameter](#)

IDLitParameter::SetParameterSet

The IDLitParameter::SetParameterSet function method is used to associate an IDLitParameterSet object with the visualization object's parameter interface. IDLitData objects contained in the parameter set object will be associated with the registered parameters of the visualization object, either based on the parameter names included in the parameter set object or on the iTool data types of the data objects. When the association of the parameter set's data objects with the visualization object's registered parameters is complete, the onDataChangeUpdate method is called with the IDLitParameterSet object and the string '<PARAMETER SET>' as the arguments.

Note

When this method is called, the IDLitParameterSet object created when the visualization object was initialized will be disassociated from the object's parameter interface. This means that any individual data objects or parameter names previously added to the initial parameter set object will also be disassociated from the visualization object's parameter interface.

This method will not destroy or delete the information contained in the specified IDLitParameterSet object.

Syntax

Result = *Obj*->[IDLitParameter::]SetParameterSet(*ParamSet*)

Return Value

Returns 1 if the IDLitParameterSet object was successfully associated with the visualization object's parameter interface, or 0 otherwise.

Arguments

ParamSet

An IDLitParameterSet object to be associated with the visualization object's parameter interface.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameterSet

The IDLitParameterSet class is a specialized subclass of the IDLitDataContainer class that provides the ability to associate names with the contained IDLitData objects. This association allows the iTool developer to package a set of data parameters in a single container, which is then provided to the iTools system for processing a display.

In addition to providing a mechanism for associating IDLitData objects with parameter names, the IDLitParameterSet class allows you to incorporate an IDLitData object for which no parameter name is provided. These *auxiliary data* items are treated as parameters for which the parameter name is a null string (' '). The auxiliary data mechanism allows you to associate any amount of data with a parameter set without the need to define parameter names.

This class is written in the IDL language. Its source code can be found in the file `idlitparameterset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitDataContainer](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitParameterSet::Init](#)” on page 4943.

Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

Methods

This class has the following methods:

- [IDLitParameterSet::Add](#)

- [IDLitParameterSet::Cleanup](#)
- [IDLitParameterSet::Copy](#)
- [IDLitParameterSet::Get](#)
- [IDLitParameterSet::GetByName](#)
- [IDLitParameterSet::GetParameterName](#)
- [IDLitParameterSet::Init](#)
- [IDLitParameterSet::Remove](#)

In addition, this class inherits the methods of its superclass.

Examples

See [Chapter 3, “Data Management”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
-----	------------

IDLitParameterSet Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

Objects in this class inherit:

- [IDLitDataContainer](#)

IDLitParameterSet::Add

The IDLitParameterSet::Add procedure method is used to add a data object to the parameter set.

Syntax

```
Obj->[IDLitParameterSet::]Add, Data [, PARAMETER_NAME=string]  
[, /PRESERVE_LOCATION]
```

Arguments

Data

An object reference or array of object references to IDLitData objects to be added to the parameter set.

Note

The objects to be added must be of class type IDLitData or a subclass of IDLitData. You cannot add the same Parameter Set object to itself.

Keywords

PARAMETER_NAME

Set this keyword to a string or array of strings containing the names of parameters to be associated with the data objects. If this value is not provided, a null string (' ') is associated with the data object. If the value of this keyword is an array with fewer elements than the array specified as the *Data* argument, null strings are associated with data objects for which no parameter name is specified.

PRESERVE_LOCATION

Set this keyword to leave the PARENT property of all data items specified by the *Data* argument unchanged. Normally, when an item is added to a parameter set (or any data container), the item's PARENT property is changed to be the parameter set or data container object. This, in turn, changes the data item's identifier string, since the item's location in the iTools hierarchy has changed. (See [“iTool Object Identifiers”](#) (Chapter 2, *iTool Developer's Guide*) for details.) In many cases, it is desirable to leave the PARENT property unchanged when adding items to a parameter set.

Version History

6.0	Introduced
-----	------------

See Also

[IDLitParameterSet::Remove](#)

IDLitParameterSet::Cleanup

The IDLitParameterSet::Cleanup procedure method performs all cleanup on the parameter set object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitParameterSet::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameterSet::Copy

The IDLitParameterSet::Copy function method will return a copy of the parameter set and its contents. All items contained in the parameter set (and their data) are copied and added to the new parameter set.

For individual data objects contained in the parameter set, the following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

Note

If the data within the contained data object consists of object references, only the object references are copied.

Note

When a parameter set is copied, a new copy of each item in the parameter set is created with a new, unique, iTool identifier, even if the data item was originally added with the PRESERVE_LOCATION keyword set.

Syntax

```
Result = Obj->[IDLitParameterSet:]Copy()
```

Return Value

Returns an IDLitParameterSet object that is a copy of the parameter set object on which the method was called.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameterSet::Get

The IDLitParameterSet::Get function method is used to retrieve one or more IDLitData objects from the parameter set.

Syntax

```
Result = Obj->[IDLitParameterSet::]Get( [ ,/ALL ] [ , COUNT=variable ]  
    [ , NAME=variable ] [ , POSITION=integer ] )
```

Return Values

Returns an object reference or array of object references to the IDLitData objects specified, or returns -1 if the method fails.

Arguments

None

Keywords

ALL

Set this keyword to return an array containing object references to all IDLitData items in the parameter set.

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

NAME

Set this keyword equal to a named variable that will contain a string or string array of the parameter names associated with the returned IDLitData objects. If a returned data object has no parameter name, a null string (' ') is returned.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the desired IDLitData objects within the parameter set.

Version History

6.0	Introduced
-----	------------

IDLitParameterSet::GetByName

The IDLitParameterSet::GetByName function method returns the IDLitData object associated with a specified named parameter.

Syntax

```
Result = Obj->[IDLitParameterSet:]GetByName( Names [, COUNT=variable]  
[, NAME=variable] )
```

Return Value

An object reference or array of object references to the IDLitData objects specified by the *Names* argument. If no matching parameter names are found, a null object is returned.

Note

If multiple parameter names are specified, the IDLitData objects are returned in the order in which they are stored in the IDLitParameterSet object, which is not necessarily the same as the order specified in the *Names* argument. Use the value returned by the NAME keyword to associate the parameter names with IDLitData objects in the returned array.

Arguments

Names

A scalar string or string array that contains the parameter names of the IDLitData objects to be retrieved from the parameter set.

Note

Parameter names can be supplied in any case; the search is case insensitive.

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

NAME

Set this keyword equal to a named variable that will contain a scalar string or string array of the parameter names of the IDLitData objects returned by this method. When multiple parameter names are specified via the *Names* argument, the array returned in the NAME variable can be used to sort through the returned IDLitData objects by matching the indices of the two returned arrays.

Version History

6.0	Introduced
-----	------------

IDLitParameterSet::GetParameterName

The IDLitParameterSet::GetParameterName function method retrieves the name of a specified parameter using a provided data object.

Syntax

Result = *Obj*->[IDLitParameterSet:]GetParameterName(*Data*, *Name*)

Return Value

Returns an integer 1 if a parameter name was found for the specified IDLitData object, or 0 if no parameter name was found.

Arguments

Data

An IDLitData object for which the parameter name is being requested.

Name

A named variable that will contain the parameter name associated with the object specified by the *oData* argument. If no parameter name is associated with the object specified by the *oData* argument, a null string (' ') is returned.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitParameterSet::Init

The IDLitParameterSet::Init function method initializes the IDLitParameter object.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitParameterSet')
```

or

```
Result = Obj->[IDLitParameterSet::]Init() (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

None

Keywords

The IDLitParameterSet object has no properties of its own, but inherits the properties of its superclass, IDLitDataContainer. Any property listed under [“IDLitDataContainer Properties”](#) on page 4744 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitParameterSet::Remove

The IDLitParameterSet::Remove procedure method is used to remove a data item from the parameter set.

Syntax

```
Obj->[IDLitParameterSet::]Remove [, Items] [, /ALL] [, POSITION=integer]
```

Arguments

Items

An object reference or array of object references to IDLitData objects to be removed from the parameter set.

Keywords

ALL

Set this keyword to remove all items from the parameter set. If this keyword is set, the *Items* parameter is not required.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices within the parameter set of the specified IDLitData objects to be removed. If this keyword is set, the *Items* parameter is not required.

Version History

6.0	Introduced
-----	------------

[IDLitParameterSet::Add](#)

IDLitReader

The IDLitReader class defines the interface used to construct file readers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file reader class.

This class is written in the IDL language. Its source code can be found in the file `idlitreader__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

[IDLitIMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitReader::Init](#)” on page 4954.

Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Methods

This class has the following methods:

- [IDLitReader::Cleanup](#)
- [IDLitReader::GetData](#)
- [IDLitReader::GetFileExtensions](#)
- [IDLitReader::GetFilename](#)
- [IDLitReader::GetProperty](#)

- [IDLitReader::Init](#)
- [IDLitReader::IsA](#)
- [IDLitReader::SetFilename](#)
- [IDLitReader::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 9, “Creating a File Reader”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
-----	------------

IDLitReader Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

Objects in this class inherit:

- [IDLitComponent](#)
- [IDLitMessaging](#)

IDLitReader::Cleanup

The IDLitReader::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitReader:]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitReader::GetData

The IDLitReader::GetData function method is called by the system to retrieve the data from the current file. When called, the reader should access the current filename and read the desired data. Once the information is loaded, the reader should place the obtained data in a data object, which is then passed back to the system.

This method will contain a majority of the implementation for a new reader class.

Your file reader must implement the GetData method and create an iTool data object.

Syntax

```
Result = Obj->[IDLitReader::]GetData(Data)
```

Return Value

Returns a 1 if successful, or a 0 if the read operation failed.

Arguments

Data

A data object that contains the read information. The reader determines the exact type and format of this data object, which keys off the type of information being read and what the format supports.

Keywords

None

Version History

6.0	Introduced
-----	------------

See Also

[“Creating a File Reader”](#) (Chapter 9, *iTool Developer’s Guide*)

IDLitReader::GetFileExtensions

The IDLitReader::GetFileExtensions function method is called by the system to retrieve the file extensions supported by this particular reader.

Syntax

Result = *Obj*->[IDLitReader::]GetFileExtensions([, COUNT=*variable*])

Return Value

Returns a scalar or string array that contains the file extensions associated with this reader.

Arguments

None

Keywords

COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

Version History

6.0	Introduced
-----	------------

IDLitReader::GetFilename

The IDLitReader::GetFilename function method is called by the system to retrieve the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then read at a later time. This method allows direct access to the file currently associated with the reader.

In addition, this methodology is helpful when multiple reads are performed from a given file.

Syntax

Result = *Obj*->[IDLitReader::]GetFilename()

Return Value

Returns a string containing the current file name associated with this reader, or an empty string if no filename has been associated.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitReader::GetProperty

The IDLitReader::GetProperty procedure method retrieves the value of an IDLitReader property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitReader:]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitReader Properties](#)” on page 4948 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitReader::Init

The IDLitReader::Init function method initializes the IDLitReader object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLitReader' [, Extensions] [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitReader::]Init( [, Extensions] [, PROPERTY=value] ) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

Extensions

A optional argument containing a scalar or string array with the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (i.e., a correct value is 'jpeg' and not '.jpeg'). If this argument is not set, or if a null string is provided, IDL does not include this file reader in the list of filters in a file-selection dialog, but still uses it when attempting to match a file to a reader.

Keywords

Any property listed under “[IDLitReader Properties](#)” on page 4948 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitReader::IsA

The IDLitReader::IsA function method is called by the system to determine if the given file is of the type supported by this file reader. Often this is used to determine what file reader to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new reader is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

Syntax

```
Result = Obj->[IDLitReader::]IsA(Filename)
```

Return Value

Returns a 1 if the reader supports this type of file, or a 0 if the reader does not support this type of file.

Arguments

Filename

A string representing of the filename, which is used to check and determine if the reader supports its format.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitReader::SetFilename

The IDLitReader::SetFilename procedure method is called by the system to set the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then the read at a later time.

Syntax

Obj->[IDLitReader::SetFilename](#), *Filename*

Arguments

Filename

A string that contains the filename associated with this reader.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitReader:: SetProperty

The IDLitReader::SetProperty procedure method sets the value of an IDLitReader property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitReader::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLitReader Properties](#)” on page 4948 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitTool

The IDLitTool class represents all the functionality provided by a particular instance of an IDL Intelligent Tool. It provides the management systems for the underlying iTool functionality and implements the desired interfaces for external parties to interact with this functionality in a known manner.

This class is written in the IDL language. Its source code can be found in the file `idlittool__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Note on the IDLitToolbase Class

All iTools included with the IDL release are based on a subclass of the IDLitTool class named IDLitToolbase. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in “[Subclassing from the IDLitToolbase Class](#)” (Chapter 5, *iTool Developer's Guide*).

Superclasses

[IDLitContainer](#)

[IDLitMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitTool::Init](#)” on page 4994.

Properties

Objects of this class have the following properties. See “[IDLitTool Properties](#)” on page 4963 for details on individual properties.

- [DESCRIPTION](#)

- [ICON](#)
- [NAME](#)
- [TYPE](#)
- [UPDATE_BYTYPE](#)
- [VERBOSE](#)
- [VERSION](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [IDLitTool::ActivateManipulator](#)
- [IDLitTool::Add](#)
- [IDLitTool::AddService](#)
- [IDLitTool::Cleanup](#)
- [IDLitTool::CommitActions](#)
- [IDLitTool::DisableUpdates](#)
- [IDLitTool::DoAction](#)
- [IDLitTool::DoSetProperty](#)
- [IDLitTool::DoUIService](#)
- [IDLitTool::EnableUpdates](#)
- [IDLitTool::FindIdentifiers](#)
- [IDLitTool::GetCurrentManipulator](#)
- [IDLitTool::GetFileReader](#)
- [IDLitTool::GetFileWriter](#)
- [IDLitTool::GetManipulators](#)
- [IDLitTool::GetOperations](#)
- [IDLitTool::GetProperty](#)
- [IDLitTool::GetSelectedItems](#)
- [IDLitTool::GetService](#)

- [IDLitTool::GetThumbnail](#)
- [IDLitTool::GetVisualization](#)
- [IDLitTool::Init](#)
- [IDLitTool::RefreshCurrentWindow](#)
- [IDLitTool::Register](#)
- [IDLitTool::RegisterCustomization](#)
- [IDLitTool::RegisterFileReader](#)
- [IDLitTool::RegisterFileWriter](#)
- [IDLitTool::RegisterManipulator](#)
- [IDLitTool::RegisterOperation](#)
- [IDLitTool::RegisterStatusBarSegment](#)
- [IDLitTool::RegisterVisualization](#)
- [IDLitTool::SetProperty](#)
- [IDLitTool::UnRegister](#)
- [IDLitTool::UnRegisterCustomization](#)
- [IDLitTool::UnRegisterFileReader](#)
- [IDLitTool::UnRegisterFileWriter](#)
- [IDLitTool::UnRegisterManipulator](#)
- [IDLitTool::UnRegisterOperation](#)
- [IDLitTool::UnRegisterStatusBarSegment](#)
- [IDLitTool::UnRegisterVisualization](#)

In addition, this class inherits the methods of its superclasses.

Examples

See “[Example: Simple iTool](#)” (Chapter 5, *iTool Developer’s Guide*).

IDLitTool Properties

IDLitTool objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitTool::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitTool::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitTool::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [DESCRIPTION](#)
- [ICON](#)
- [NAME](#)
- [TYPE](#)
- [UPDATE_BYTYPE](#)
- [VERBOSE](#)
- [VERSION](#)

In addition, objects of this class inherit:

- [IDLitContainer](#)
- [IDLitMessaging](#)

DESCRIPTION

This property contains a string representing the full name or description of this object.

Property Type	STRING		
Name String	Description		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

ICON

A string identifying the icon that should be used when displaying the iTool object. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for additional details.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

NAME

A string representing the name of this object.

Property Type	STRING		
Name String	Name		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TYPE

A string or vector of strings that identify the type(s) that this iTool represents.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

UPDATE_BYTYPE

A Boolean value controlling whether the given iTool will add new functionality to it as new visualization types are added. By default, when a new visualization is added to the iTool, any functionality associated with that visualization type is added to the iTool. If this property is set to zero (False), this updating is disabled.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

VERBOSE

A named variable that will control the verbose logging of the iTool. If set to a non-zero value, the iTool will log more information than normal. If this keyword is set to 0, minimal logging (error conditions only) will be sent to the logging system.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERSION

A named variable that will be set to the version of the iTool system.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLitTool::ActivateManipulator

Version History

The IDLitTool::ActivateManipulator procedure method activates a manipulator that has been registered with this tool.

Syntax

Obj->[IDLitTool:]ActivateManipulator, *Identifier* [, /DEFAULT]

Arguments

Identifier

A string representing the identifier of the manipulator to activate.

Keywords

DEFAULT

Set this keyword to a non-zero value to indicate that the default manipulator registered with this tool should be activated. If this keyword is set, the Identifier argument is ignored.

Version History

6.1	Introduced
-----	------------

IDLitTool::Add

The IDLitTool::Add procedure method adds any item to the iTool. If called with a Visualization, that visualization is added to the current IDLitWindow object. If called with a data object, that data object is placed in the systems data manager. All other items are added to the iTool container.

Syntax

Obj->[IDLitTool:]Add, *Item*

Arguments

Item

The item to add to the iTool.

Keywords

This method passes keywords to the Add method of the appropriate object. If the target destination is a data object, no keywords are passed. If the target destination is a visualization object, the keywords are passed to the IDLitWindow::Add method; otherwise, the keywords are passed to the IDLitContainer::Add method.

Version History

6.0	Introduced
-----	------------

IDLitTool::AddService

The `IDLitTool::AddService` procedure method adds a service to the iTool. Unlike the *register* methods, which register the definition of an object class to be instantiated later, this method takes an existing object instance and adds it to the service repository in the iTool.

The relative identifier for the service added will be `SERVICES/identifier`, where *identifier* is the value of the `IDENTIFIER` property of the service object.

Syntax

Obj->`[IDLitTool::]AddService, oService`

Arguments

oService

An object reference to the service to be added to the service repository.

Note

The service object reference can be retrieved later by providing the service's object identifier to the `IDLitTool::GetService` method.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::Cleanup

The IDLitTool::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitTool::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::CommitActions

The IDLitTool::CommitActions procedure method commits all pending transactions to the undo-redo buffer and causes a refresh of the current window.

This method is designed to be used in conjunction with the [IDLitTool::DoSetProperty](#) method.

Syntax

Obj->[\[IDLitTool::\]](#)CommitActions

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

See Also

[IDLitTool::DoSetProperty](#)

IDLitTool::DisableUpdates

The IDLitTool::DisableUpdates procedure method disables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates are re-enabled by calling the EnableUpdates method.

Syntax

Obj->[IDLitTool:]DisableUpdates [, PREVIOUSLY_DISABLED=*variable*]

Arguments

None

Keywords

PREVIOUSLY_DISABLED

Set this keyword to a named variable that upon return will be 1 if the tool had previously been disabled, or 0 otherwise.

Version History

6.0	Introduced
6.1	Added PREVIOUSLY_DISABLED keyword

IDLitTool::DoAction

The IDLitTool::DoAction function method initiates an operation or action in the iTool object. The identifier that is passed in as the argument to this method specifies the action that executes.

Syntax

Result = *Obj*->[IDLitTool::]DoAction(*Identifier*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation that it implements.

Keywords

All keywords are passed to the DoAction function of the object in the iTool that performs the operation.

Version History

6.0	Introduced
-----	------------

IDLitTool::Do SetProperty

The IDLitTool::Do SetProperty function method sets the value of a registered property on a target component object, and places the change in the undo/redo transaction buffer.

Note

In order to commit the change to the undo/redo transaction buffer, you must call the [IDLitTool::CommitActions](#) method. The property change is not actually undoable until it has been committed.

The separation of addition of the change to the buffer and commit of the change allows you to “package” several property changes into a single undo/redo transaction. The call to the CommitActions method will commit any changes that have been performed but not committed. For example, the following statements change two properties on an iTool component (oTarget) and commit them together:

```
targetID = oTarget->GetFullIdentifier()
status = oTool->DoSetProperty(targetID, 'Property1', 'Value 1')
status = oTool->DoSetProperty(targetID, 'Property2', 'Value 2')
oTool->CommitActions
```

If the user later undoes the action, both property value changes will be reversed in one step.

Syntax

```
Result = Obj->[IDLitTool::]DoSetProperty(TargetIdentifier, PropertyIdentifier,  
Value)
```

Return Value

Returns 1 if the SetProperty was successful, or 0 otherwise.

Note

If successful, you are responsible for calling IDLitTool::CommitActions to complete the transaction.

Arguments

TargetIdentifier

A scalar string or a string array containing the full object identifiers of the objects on which the property is being set.

PropertyIdentifier

A scalar string containing the identifier of the property whose value is being changed. *PropertyIdentifier* must be a registered property of the target objects.

Value

The new property value.

Keywords

None

Version History

6.0	Introduced
-----	------------

[IDLitTool::CommitActions](#)

IDLitTool::DoUIService

The IDLitTool::DoUIService function method initiates a request for a UI service to execute. This method allows underlying iTool functionality to perform user-interface interactions without having a direct connection to the user interface portion of the iTool.

An example of an iTool UI service would be the **File** → **Open** command, which will prompt the user to select a file using the standard file open dialog. This command is identified by setting the *ServiceIdentifier* argument to `FileOpen`. See [Chapter 13, “Creating a User Interface Service”](#) (*iTool Developer’s Guide*) for more information about UI services.

Syntax

Result = *Obj*->[IDLitTool::]DoUIService(*ServiceIdentifier*, *Requestor*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

ServiceIdentifier

A string identifier that specifies the UI service being requested. This identifier is passed to the tools user interface for control dispatching purposes.

Requestor

An object reference to the object that is requesting the UI service. The UI service uses this object to obtain any information particular to the interaction taking place.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::EnableUpdates

The IDLitTool::EnableUpdates procedure method re-enables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates can be disabled by calling the DisableUpdates method.

Syntax

Obj->[IDLitTool:]EnableUpdates

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::FindIdentifiers

The IDLitTool::FindIdentifiers function method allows you to retrieve the full identifiers for items within the tool container.

Warning

The FindIdentifiers method recurses through the entire object hierarchy of the specified object, which may be slow for large container hierarchies. If you find it necessary to call FindIdentifiers multiple times, it may be more efficient to use a single call with one or more wildcards (“*”) to return all relevant identifiers, and then perform the necessary searches using the returned list.

Syntax

```
Result = Obj->[IDLitTool::]FindIdentifiers([Pattern] [, /ANNOTATIONS]
    [, COUNT=variable] [, /DATA_MANAGER] [, /FILE_READERS]
    [, /FILE_WRITERS] [, /LEAF_NODES] [, /MANIPULATORS]
    [, /OPERATIONS] [, /VISUALIZATIONS] )
```

Return Value

Returns a scalar string or string array containing the full object identifiers for all items matching the *Pattern*. If no object identifiers are matched, the function returns a scalar null string.

Arguments

Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match *Pattern* are returned. Matching is case insensitive. If *Pattern* is not supplied, identifiers for all objects within the object on which this method is called are returned. See [STRMATCH](#) for a description of the rules used when matching patterns. See “[Retrieving Component Identifiers](#)” (Appendix A, *iTool Developer’s Guide*) for additional information and examples.

Note

Objects for which the PRIVATE property contains a True value are not included in the *Result*. Only objects that subclass from IDLitComponent can be marked as private.

Keywords

ANNOTATIONS

Set this keyword to only return identifiers for items within the annotation layer of all views within the graphics window.

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers in *Result*.

DATA_MANAGER

Set this keyword to only return identifiers for items within the Data Manager container.

FILE_READERS

Set this keyword to only return identifiers for items within the File Readers container.

FILE_WRITERS

Set this keyword to only return identifiers for items within the File Writers container.

LEAF_NODES

Set this keyword to return only leaf nodes. Leaf nodes are objects which are either not a container, or are an empty container.

Note

If all of the objects within a container are marked as `PRIVATE`, then that container is considered a leaf node. Only objects that subclass from `IDLitComponent` can be marked as private.

MANIPULATORS

Set this keyword to only return identifiers for items within the Manipulators container.

OPERATIONS

Set this keyword to only return identifiers for items within the Operations container.

VISUALIZATIONS

Set this keyword to only return identifiers for items within the Visualization layer of all views within the graphics window.

Example

This example finds the plot visualization and changes the color:

```
IPLOT, RANDOMU(S,100)
void = IGETCURRENT(TOOL=oTool)

; Find the Plot visualization and change the color.
id = oTool->FindIdentifiers('*plot*', /VISUALIZATIONS)

void = oTool->DoSetProperty(id, 'COLOR', [255,0,0])
```

This example finds the file open operation and loads in an image:

```
IIMAGE
void = IGETCURRENT(TOOL=oTool)

; Find the File Open operation and open a file.
id = oTool->FindIdentifiers('*File/Open*', /OPERATIONS)

oOp = oTool->GetByIdentifier(id)
oOp->SetProperty, SHOW_EXECUTION_UI=0, $
    FILENAMES=FILEPATH('rose.jpg', SUBDIR=['examples', 'data'])
void = oTool->DoAction(id)
oOp->SetProperty, SHOW_EXECUTION_UI=1
```

Version History

6.1	Introduced
-----	------------

[“Retrieving Component Identifiers”](#) (Appendix A, *iTool Developer’s Guide*)

IDLitTool::GetCurrentManipulator

The IDLitTool::GetCurrentManipulator function method returns the current manipulator in the system.

Syntax

Result = *Obj*->[IDLitTool::]GetCurrentManipulator()

Return Value

Returns an object reference to the current manipulator.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::GetFileReader

The IDLitTool::GetFileReader function method retrieves a file reader registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

```
Result = Obj->[IDLitTool::]GetFileReaders(Identifier [, /ALL]  
[, COUNT=variable])
```

Return Value

Returns the object descriptors constructed for the registered file reader.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file readers registered with the system.

Arguments

Identifier

A string representing the single level identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

Keywords

ALL

Set this keyword to return all file readers registered with the iTool and the system.

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

6.0	Introduced
-----	------------

IDLitTool::GetFileWriter

The IDLitTool::GetFileWriter function method retrieves a file writer registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

```
Result = Obj->[IDLitTool::]GetFileWriters(Identifier [, /ALL]  
[, COUNT=variable])
```

Return Value

Returns the object descriptors constructed for the registered file writer.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file writers registered with the system.

Arguments

Identifier

A string representing the identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

Keywords

ALL

Set this keyword to return all file writers registered with the iTool and the system.

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

6.0	Introduced
-----	------------

IDLitTool::GetManipulators

The IDLitTool::GetManipulators function method retrieves the manipulators registered with the iTool object. Unlike other items in the iTool and due to the active nature of the subsystem, manipulators are instantiated when registered.

Syntax

Result = *Obj*->[IDLitTool::]GetManipulators([, **COUNT**=*variable*])

Return Value

Returns the object references to the manipulators that were instantiated when items were registered with the iTool.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

Version History

6.0	Introduced
-----	------------

IDLitTool::GetOperations

The IDLitTool::GetOperations function method retrieves the operations registered with the iTool object.

Note

This routine returns a set of object descriptor classes that reference the items registered with the iTool. In addition, if the operation folder in the registry contains sub-folders, the returned list will contain IDLitContainer classes, each containing sub-operations.

Syntax

```
Result = Obj->[IDLitTool::]GetOperations([, COUNT=variable]
[, IDENTIFIER=string] )
```

Return Value

Returns the object descriptors constructed for the registered operations.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

IDENTIFIER

Set this keyword to an optional identifier that identifies the location in the operation hierarchy to retrieve the operation object descriptors from.

Version History

6.0	Introduced
-----	------------

IDLitTool::GetProperty

The IDLitTool::GetProperty procedure method retrieves the value of an IDLitTool property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitTool::](#)GetProperty, [*PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitTool Properties](#)” on page 4963 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitTool::GetSelectedItems

The IDLitTool::GetSelectedItems function method returns a vector of references to the objects currently selected within the current window in the iTool. If no objects are currently selected, this function returns -1.

Syntax

Result = *Obj*->[IDLitTool::]GetSelectedItems([, **COUNT**=*variable*])

Return Value

Returns a vector of references to the currently selected objects. If no objects are currently selected, this function returns -1.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of valid items returned by this function.

Version History

6.0	Introduced
-----	------------

IDLitTool::GetService

The IDLitTool::GetService method retrieves a service that has been registered with the iTool.

Syntax

Result = *Obj*->[IDLitTool::]GetService(*IdService*)

Return Value

Returns an object reference for the service.

Arguments

IdService

The relative identifier of the desired service.

Note

IdService should specify only the relative identifier, not the fully-qualified identifier. See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for details.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::GetThumbnail

The IDLitTool::GetThumbnail method retrieves a thumbnail image of the current iTool.

Syntax

```
Result = Obj->[IDLitTool::]GetThumbnail( [, THUMBBACKGROUND=variable]  
[, /THUMBORDER] [, THUMBSIZE=variable] )
```

Return Value

Returns a True Color (3xmxm) image.

Arguments

None

Keywords

THUMBBACKGROUND

Set this keyword to specify the color of the background to use in the thumbnail. This keyword has an effect only if the aspect ratio of the tool window is not equal to 1. If set to a scalar value, the color of the lower left pixel of the tool window is used as the background color. If set to an RGB triplet, the supplied color will be used. If a value is not specified, a default value of [255,255,255] (white) is used.

THUMBORDER

Set this keyword to return the thumbnail in top-to-bottom order rather than the IDL default of bottom-to-top order.

THUMBSIZE

Set this keyword to the size of the thumbnail to return. A thumbnail is always returned as a square image. If a value is not supplied, a default value of 32 is used. THUMBSIZE must be greater than 3 and must shrink the tool window.

Version History

7.1	Introduced
-----	------------

IDLitTool::GetVisualization

The IDLitTool::GetVisualization function method retrieves a visualization registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

Syntax

```
Result = Obj->[IDLitTool::]GetVisualization(Identifier [, /ALL]  
[, COUNT=variable])
```

Return Value

Returns the object descriptors constructed for the registered visualizations. (See “iTool Object Identifiers” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object descriptors.)

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool as well as those visualizations registered with the system.

Arguments

Identifier

A string containing the relative identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call. (See “iTool Object Identifiers” (Chapter 2, *iTool Developer’s Guide*) for a discussion of relative vs. fully-qualified identifiers.)

Keywords

ALL

Set this keyword to return all visualizations registered with the iTool and the system.

COUNT

Set this keyword to a variable that will contain the number of object descriptors returned by this method. (See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced
-----	------------

IDLitTool::Init

The IDLitTool::Init function method initializes the IDLitTool object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitTool'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitTool::]Init( [, PROPERTY=value)  (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [“IDLitTool Properties”](#) on page 4963 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitTool::RefreshCurrentWindow

The IDLitTool::RefreshCurrentWindow procedure method redraws the current window of the iTool. The redraw will occur only if updates are enabled in the iTool.

Syntax

Obj->[IDLitTool::](#)RefreshCurrentWindow

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitTool::Register

The IDLitTool::Register procedure method registers a generic object subclassed from the IDLitComponent class with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed. Unlike the other provided methods to register components, this method is generic.

This method allows items to be registered in the standard registry folders of the IDLitTool object, and can be used as well for the creation of new folders. If the provided identifier specifies a folder that does not currently exist in the iTool, it is created.

Note

For information on registering functionality with the iTool system, making the registered functionality available to all iTools, see [IREGISTER](#).

This method performs none of the validation performed by the specific registration functions. As such, it can cause issues with iTool operation, if used incorrectly. You should use the following related methods for registering certain, specific components to insure validation:

- File readers — “[IDLitTool::RegisterFileReader](#)” on page 5001
- File writers — “[IDLitTool::RegisterFileWriter](#)” on page 5004
- Manipulators — “[IDLitTool::RegisterManipulator](#)” on page 5007
- Operations — “[IDLitTool::RegisterOperation](#)” on page 5009
- Visualizations — “[IDLitTool::RegisterVisualization](#)” on page 5014

Syntax

```
Obj->IDLitTool::Register, Name, ClassName [, /DEFAULT]  
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]  
    [, PROXY=string]
```

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

Note

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the item being registered should be the *default item* of its type. Making an item the default places the item first in the list of items of its type. When the iTool system chooses an item, it will use the first item in the list that matches the data type of the selected data. When items are displayed in a list for the user to select from, the default item will appear at the top of the list.

For example, if you register a visualization type with the DEFAULT keyword set, your visualization type will be used by the iTool (assuming the selected data is of the proper type) unless you specifically choose a different visualization type.

Note

If you register more than one item with the DEFAULT keyword set, the *last* item registered will appear *first* in the list of items of that type.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the iTool object. See [“System Resources”](#) (Chapter 2, *iTool Developer’s Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this component type. If not provided, an identifier is constructed from the provided *Name* value.

To use one of the iTool-provided registration locations, the value of this keyword should contain the destination for the new component that is being registered. Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed to this item are routed to the item specified by the identifier provide to this keyword. (See [“iTool Object Identifiers”](#) (Chapter 2, *iTool Developer’s Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced
6.1	Added DEFAULT keyword

IDLitTool::RegisterCustomization

The IDLitTool::RegisterCustomization procedure method registers an operation class that represents the graphics customization operation to be associated with this tool.

Syntax

Obj->[IDLitTool::]RegisterCustomization, *Name*, *ClassName*

Arguments

Name

A string representing the name of the customization operation.

ClassName

A string representing the classname of the operation being registered.

Keywords

Note

Any keywords provided to this routine are treated as property defaults for the registered operation and applied to the registered object when it is created.

Version History

6.1	Introduced
-----	------------

IDLitTool::RegisterFileReader

The IDLitTool::RegisterFileReader procedure method registers a file reader component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a reader class is registered with the iTool, an object descriptor for this operation class is placed in the iTool's file reader folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE_READERS/identifier`, where `identifier` is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool:]RegisterFileReader, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

Arguments

Name

The human readable name of the component type being registered with the iTool.

Note

If the `IDENTIFIER` keyword is not supplied, the `Name` argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the file reader being registered should be the *default* file reader. When the iTool system picks a reader for a file of the specified type, it will attempt to use the specified file reader first. The file reader will also be displayed at the top of the list of file readers displayed for the user to select from.

Note

If you register more than one file reader with the DEFAULT keyword set, the *last* file reader registered will appear *first* in the list of items of file readers.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the file reader in an iTool browser. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file reader registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced
6.1	Added DEFAULT keyword

[IREGISTER](#)

IDLitTool::RegisterFileWriter

The IDLitTool::RegisterFileWriter procedure method registers a file writer component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a writer class is registered with the system, an object descriptor for this operation class is placed in the iTool's file writer folder. To retrieve this descriptor at a later time, the iTool relative identifier would be FILE WRITERS/identifier, where identifier is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool:]RegisterFileWriter, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

Note

If the IDENTIFIER keyword is not supplied, the Name argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the component being registered. The iTool object uses this class name to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

Set this keyword to specify that the file writer being registered should be the *default* file writer. When the iTool system picks a writer for a file of the specified type, it will attempt to use the specified file writer first. The file writer will also be displayed at the top of the list of file writers displayed for the user to select from.

Note

If you register more than one file writer with the DEFAULT keyword set, the *last* file writer registered will appear *first* in the list of file writers.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the file writer in an iTool browser. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file writer registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object descriptors.)

Version History

6.0	Introduced
6.1	Added DEFAULT keyword

See Also

[IREGISTER](#)

IDLitTool::RegisterManipulator

The IDLitTool::RegisterManipulator procedure method registers a manipulator component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a manipulator class is registered with the system, an object of the given class is created and added to the tools manipulator manager (an instance of IDLitManipulatorManager). To reference the new manipulator, the identifier that is provided should be prepended with the MANIPULATORS identifier level.

Syntax

```
Obj->[IDLitTool:]RegisterManipulator, Name, ClassName [, /DEFAULT]  
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
```

Arguments

Name

A string containing the human readable name of the component type being registered with the iTool.

Note

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

If set, this registered item will be treated as the default manipulator for this iTool. Only one default manipulator can exist at anytime.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the manipulator in an iTool menubar. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

Version History

6.0	Introduced
-----	------------

IDLitTool::RegisterOperation

The IDLitTool::RegisterOperation procedure method registers an operation component with the iTool. Once registered, the iTool has the ability to instantiate this type of operation when needed.

When an operation class is registered with the system, an object descriptor for this operation class is placed in the tools operations folder. To retrieve this descriptor at a later time, the iTool relative identifier would be OPERATIONS/identifier, where identifier is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool:]RegisterOperation, Name, ClassName  
    [, ACCELERATOR=string] [, /CHECKED] [, DESCRIPTION=string]  
    [, /DROPLIST_EDIT] [, DROPLIST_INDEX=value]  
    [, DROPLIST_ITEMS=string array] [, ICON=string] [, IDENTIFIER=string]  
    [, PROXY=string] [, /SEPARATOR]
```

Arguments

Name

A string containing the human readable name of the operation type being registered with the iTool.

Note

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the operation component being registered. This class name is used by the iTool object to instantiate an operation component of this type when requested.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

ACCELERATOR

Set this keyword to a string giving the keyboard accelerator to be used for the menu item associated with this operation. For valid values see the ACCELERATOR keyword to WIDGET_BUTTON.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

CHECKED

Set this keyword to indicate that a “checked” menu item should be used for this operation.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

DROPLIST_EDIT

Set this keyword to indicate that a droplist associated with this operation should be editable (that is, the droplist should be a combobox widget). The default is to create a non-editable droplist widget. The DROPLIST_ITEMS keyword must be set for this keyword to have any effect.

Note

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

DROPLIST_INDEX

Set this keyword equal to the starting index of the droplist associated with this operation. The default is 0 (zero). The DROPLIST_ITEMS keyword must be set for this keyword to have any effect.

Note

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

DROPLIST_ITEMS

Set this keyword equal to a scalar string or string array containing values to be used for the droplist. If this keyword is set, the DoAction method for the associated operation must accept a keyword called OPTION. When an item from the droplist is selected, the DoAction method will be called with the OPTION keyword set equal to the selected string value.

Note

This keyword is only a hint to the iTool, and may be ignored if a non-standard user interface is being used.

ICON

Set this keyword to the icon that should be used when displaying the operation in an iTool browser. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier for the iTool for this component type. If not provided, an identifier is constructed from the *Name*.

Operations are placed in the `operation` folder of the iTool component hierarchy. If a multiple level identifier is provided (indicated by the presence of one or more “/” characters), the item is placed in the corresponding subfolder of the tool’s `operation` folder. If the specified subfolder is not present, it is created. This functionality allows operations to be classified in logical groupings and results in sub-menu items in the menus of the iTool interface.

See “[iTool Object Hierarchy](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object identifiers and the iTool component hierarchy.

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of object descriptors.)

SEPARATOR

Set this keyword to indicate that a menu separator should be placed before this operation, if this operation appears in a menu.

Note

This keyword is only a hint to the Tool, and may be ignored if a non-standard user interface is being used.

Version History

6.0	Introduced
6.1	Added ACCELERATOR, CHECKED, DISABLE, DROPLIST_EDIT, DROPLIST_INDEX, DROPLIST_ITEMS, SEPARATOR keywords
6.2	Deprecated DISABLE keyword

For information on obsolete keywords, see [Appendix I, “IDL API History”](#).

IDLitTool::RegisterStatusBarSegment

The `IDLitTool::RegisterStatusBarSegment` procedure method registers a status message bar segment with the tool.

Syntax

```
Obj->[IDLitTool::]RegisterStatusBarSegment, Name [, IDENTIFIER=string]  
    [, NORMALIZED_WIDTH=scalar]
```

Arguments

Name

A scalar string containing the name of the status bar segment.

Keywords

IDENTIFIER

Set this keyword to a string containing the relative identifier for the status bar segment being registered. If this keyword is not specified, the *Name* argument is used as the identifier. See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer’s Guide*) for a discussion of iTool identifiers.

NORMALIZED_WIDTH

Set this keyword to a floating-point integer between 0 and 1.0 indicating the normalized width (relative to the overall width of the status bar) that this segment should occupy.

Version History

6.1	Introduced
-----	------------

See Also

[IDLitTool::UnRegisterStatusBarSegment](#)

IDLitTool::RegisterVisualization

The IDLitTool::RegisterVisualization procedure method registers a visualization component with the iTool. Once registered, the iTool has the ability to instantiate this type of visualization when needed.

When a visualization class is registered with the system, an object descriptor for this visualization class is placed in the iTool's visualization folder. To retrieve this descriptor at a later time, the iTool relative identifier would be:

VISUALIZATIONS/*identifier* where *identifier* is the identifier provided to this method.

Syntax

```
Obj->[IDLitTool::]RegisterVisualization, Name, ClassName [, /DEFAULT]
    [, DESCRIPTION=string] [, ICON=string] [, IDENTIFIER=string]
    [, PROXY=string]
```

Arguments

Name

A string containing the human readable name of the visualization type being registered with the iTool.

Note

If the **IDENTIFIER** keyword is not supplied, the *Name* argument will be used as the basis for the component's identifier.

ClassName

A string containing the class name of the visualization component being registered. The iTool object uses this class name to instantiate a visualization component of this type when requested.

Keywords

Note

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

DEFAULT

If set, this registered item will be treated as the default visualization for this iTool. Only one default visualization can exist at a time.

DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

ICON

Set this keyword to the icon that should be used when displaying the visualization in an iTool browser. See “[System Resources](#)” (Chapter 2, *iTool Developer’s Guide*) for additional details.

IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the visualization registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

Note

If an item with the specified identifier has already been registered with the iTool system, the existing item will be *replaced* by the new item.

PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword.

[IDLitTool::DoSetProperty](#)

IDLitTool::UnRegister

The IDLitTool::UnRegister procedure method unregisters a component with the iTool. When a component is unregistered, it is no longer available to perform whatever function it performs, and it is removed from iTool menus and toolbars.

Syntax

Obj->[IDLitTool:]UnRegister, *Identifier*

Arguments

Identifier

Set this to the relative identifier of the component to be removed from the iTool. To remove a component from the standard folders in the iTool's content registry, this identifier should contain the location of the component as well as the component identifier itself. See “[iTool Object Identifiers](#)” (Chapter 2, *iTool Developer's Guide*) for a discussion of iTool identifiers.

Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

IDLitToolbase

The IDLitToolbase class is a subclass of the IDLitTool class that *registers* all of the features (menu items, operations, manipulators, *etc.*) of a standard iTool. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in [“Subclassing from the IDLitToolbase Class”](#) (Chapter 5, *iTool Developer's Guide*).

Warning

The list of items registered by the IDLitToolbase class may change from release to release. If your aim is to have your tool present the same features as the standard iTools provided in an IDL release, subclass your tool from IDLitToolbase. If your aim is to create your own interface that stays static between releases of IDL, use IDLitToolbase as a template for your own tool, but do not subclass it directly.

This class is written in the IDL language. Its source code can be found in the file `idlittoolbase__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitTool](#)

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer's Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitTool::Init”](#) on page 4994.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

Objects of this class have no methods of their own, but do have methods inherited from any superclasses.

Examples

See [“Example: Simple *iTool*”](#) (Chapter 5, *iTool Developer’s Guide*).

Version History

6.0	Introduced

[Chapter 5, “Creating an *iTool*”](#) (*iTool Developer’s Guide*)

IDLitUI

The IDLitUI class serves as the link between the underlying functionality of an iTool and the IDL Widget interface that is displayed to the user. The user interface object provides the following functionality:

- Access to and communication with the underlying iTool object.
- Registration of various user interface elements that are part of the iTool.
- Registration and management of dialog sub-elements that are used by the iTool to perform specific tasks.

For additional information on the IDLitUI class, and user interface issues in general, see [Chapter 11, “iTool User Interface Architecture”](#) (*iTool Developer’s Guide*).

This class is written in the IDL language. Its source code can be found in the file `idlitui__define.pro` in the `lib/itools/ui_widgets` subdirectory of the IDL distribution.

Superclasses

[IDLitContainer](#)

Note

See the [“iTools Object Model Diagram”](#) (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See [“IDLitUI::Init”](#) on page 5039.

Properties

Objects of this class have the following properties. See [“IDLitUI Properties”](#) on page 5030 for details on individual properties.

- [GROUP_LEADER](#)

Methods

This class has the following methods:

- [IDLitUI::AddOnNotifyObserver](#)

- [IDLitUI::Cleanup](#)
- [IDLitUI::DoAction](#)
- [IDLitUI::GetProperty](#)
- [IDLitUI::GetTool](#)
- [IDLitUI::GetWidgetByName](#)
- [IDLitUI::Init](#)
- [IDLitUI::RegisterUIService](#)
- [IDLitUI::RegisterWidget](#)
- [IDLitUI::RemoveOnNotifyObserver](#)
- [IDLitUI::SetProperty](#)
- [IDLitUI::UnRegisterUIService](#)
- [IDLitUI::UnRegisterWidget](#)

In addition, this class inherits the methods of its superclasses (if any).

Examples

See [“Example: A Simple UI Panel”](#) (Chapter 14, *iTool Developer’s Guide*).

Version History

6.0	Introduced

[Chapter 11, “iTool User Interface Architecture”](#) (*iTool Developer’s Guide*)

IDLitUI Properties

IDLitUI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitUI::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitUI::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitUI::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [GROUP_LEADER](#)

In addition, objects of this class inherit:

- [IDLitContainer](#)

GROUP_LEADER

A long integer containing the IDL Widget ID of the group leader widget for the user interface.

Property Type	Long Integer (Widget ID)		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

IDLitUI::AddOnNotifyObserver

The IDLitUI::AddOnNotifyObserver procedure method is used to register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object.

Syntax

Obj->[IDLitUI::](#)AddOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idObject, idMessage, message
```

where

- *idObject* is the object identifier of the iTool component that is the source of the message.
- *idMessage* is a string that identifies the type of message being sent.
- *message* is the message data itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See “[IDLitMessaging::DoOnNotify](#)” on page 4799 for additional details.

IdSubject

A string identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via [IDLitMessaging::DoOnNotify](#) specifies *IdSubject* as the originator, the *IdObserver* object’s OnNotify method is called.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI::Cleanup

The IDLitUI::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitUI::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI::DoAction

The IDLitUI::DoAction function method initiates an operation or action in the iTool object associated with this user interface. The identifier that is passed in as the argument to this method specifies the action that executes.

Syntax

Result = *Obj*->[IDLitUI::]doAction(*Identifier*)

Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

Arguments

Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation or action that it implements.

Keywords

None.

Version History

6.0	Introduced
-----	------------

IDLitUI::GetProperty

The IDLitUI::GetProperty procedure method retrieves the value of an IDLitUI property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitUI::](#)GetProperty, [*PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitUI Properties](#)” on page 5030 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitUI::GetTool

The IDLitUI::GetTool function method returns an object reference to the iTool with which the user interface is associated.

Syntax

Result = *Obj*->[IDLitUI::]GetTool()

Return Value

Returns an object reference to the iTool associated with the current user interface, or a null object if there is no associated iTool.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI::GetWidgetByName

The IDLitUI::GetWidgetByName function method returns the IDL Widget ID of a widget that has been registered with the user interface object via a call to the [IDLitUI::RegisterWidget](#) method.

Syntax

Result = *Obj*->[IDLitUI:]GetWidgetByName(*Name*)

Return Value

Returns the widget identifier (a long integer) of the widget specified by the *Name* argument, or 0 if the widget was not registered with the iTool system.

Arguments

Name

Set this argument to the name that the desired widget was registered with.

Keywords

None

Example

This method can be used to determine whether a given widget already exists and act accordingly. For example, the following code checks to determine whether a widget registered as *myWidget* exists; if it does, that widget is mapped and un-iconified:

```
wID = oUI->GetWidgetByName(myWidget)
IF(wID NE 0) THEN BEGIN
    WIDGET_CONTROL, wID, /MAP, ICONIFY=0 ;; show the widget
    RETURN
ENDIF
```

Similar code is used in many of the widget interface elements used by the standard iTools included with IDL.

Version History

6.0	Introduced
-----	------------

IDLitUI::Init

The IDLitUI::Init function method initializes the IDLitUI object, and should be called by the Init method of a subclass.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitUI', oTool)
```

or

```
Result = Obj->[IDLitUI:]Init(oTool) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

oTool

An object reference to the IDLitTool object with which the user interface object is associated.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI::RegisterUIService

The IDLitUI::RegisterUIService function method registers a *user interface service* with the user interface. Once the user interface service has been registered, the iTool with which the user interface is associated can call the UI service to display dialogs or other UI elements.

Note

Every UI service must implement a callback function that displays the requested user interface. See [Chapter 13, “Creating a User Interface Service”](#) (*iTool Developer’s Guide*) for details.

Syntax

Result = Obj->[IDLitUI:]RegisterUIService(*Name*, *Callback*)

Return Value

Returns an iTool object identifier for the UI service specified by *Name*.

Arguments

Name

A string containing the human readable name of the user interface being registered.

Callback

A string containing the name of the callback function for this UI service. The callback function is called when execution of the UI service is requested. The callback should have the following calling signature:

```
FUNCTION NAME, oUI, oTarget
```

where:

- *NAME* is the name of the callback function,
- *oUI* is an object reference to the user interface object of which the UI service is a part
- *oTarget* is an object reference to the object that is the target of the operation or action with which the UI service is associated.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI::RegisterWidget

The IDLitUI::RegisterWidget function method registers an IDL widget hierarchy with the user interface object. Once a widget has been registered with the UI object, the UI can route messages to that widget and manage visibility if the widget is registered with the FLOATING property set.

Syntax

```
Result = Obj->[IDLitUI::]RegisterWidget(wID, Name, Callback[, /FLOATING])
```

Return Value

The iTool object identifier of the user interface adaptor that links the widget specified by *wID* with the iTool.

Arguments

wID

A long integer containing the widget ID of the widget being registered. This value is provided to the routine specified by the *Callback* argument when it is called.

Name

A string containing the human readable name for the widget being registered.

Callback

A string containing the name of a *callback procedure* for the widget. Any notification messages sent by the iTool to this widget are sent to this callback procedure. The callback procedure should have the following calling signature:

```
PRO NAME, wID, strID, message, messageData
```

where:

- *NAME* is the name of the callback procedure,
- *wID* is the widget ID provided to the IDLitUI::RegisterWidget method,
- *strID* is a string containing the object identifier of the iTool object that triggered the message,
- *message* is the message being sent to the callback procedure,
- *messageData* is any data associated with the message.

Note

If this argument is set to an empty string, no callbacks will be made to this widget.

Keywords

FLOATING

Set this keyword to treat the widget as a floating element of the specified iTool user interface, to be managed by the user interface object. If this keyword is set, the widget will only be visible if the associated iTool is “current,” and the widget will be destroyed when the iTool is destroyed.

Version History

6.0	Introduced
-----	------------

IDLitUI::RemoveOnNotifyObserver

The IDLitUI::RemoveOnNotifyObserver procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object. This method reverses the action of calling the [IDLitUI::AddOnNotifyObserver](#) method.

Syntax

Obj->[IDLitUI:]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

Arguments

IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can also be a string that references a global system service.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI:: SetProperty

The IDLitUI:: SetProperty procedure method sets the value of an IDLitUI property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitUI::]SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

None

Version History

6.0	Introduced

IDLitUI::UnRegisterUIService

The IDLitUI::UnRegisterUIService procedure method unregisters a user interface service with the user interface object.

Syntax

Obj->[IDLitUI::]UnRegisterUIService, *Name*

Arguments

Name

A string containing the name of the UI service to be unregistered.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitUI::UnRegisterWidget

The IDLitUI::UnRegisterWidget procedure method unregisters a widget with the user interface object.

Syntax

Obj->[IDLitUI::]UnRegisterWidget, *Name*

Arguments

Name

A string containing the name of the widget to be unregistered.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization

The IDLitVisualization class represents the base visualization component, from which all iTool visualization classes should subclass. IDLitVisualization acts as a container and provides methods for adding, removing, and grouping visualization components.

This class is written in the IDL language. Its source code can be found in the file `idlitvisualization__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLgrModel](#)

[IDLitMessaging](#)

[IDLitParameter](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitVisualization::Init](#)” on page 5078.

Properties

Objects of this class have the following properties. See “[IDLitVisualization Properties](#)” on page 5053 for details on individual properties.

- [CENTER_OF_ROTATION](#)
- [IMPACTS_RANGE](#)
- [ISOTROPIC](#)
- [MANIPULATOR_TARGET](#)
- [PROPERTY_INTERSECTION](#)
- [SELECT_TARGET](#)
- [TYPE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has all the methods associated with the superclasses, plus the following methods:

- [IDLitVisualization::Add](#)
- [IDLitVisualization::Aggregate](#)
- [IDLitVisualization::BeginManipulation](#)
- [IDLitVisualization::Cleanup](#)
- [IDLitVisualization::EndManipulation](#)
- [IDLitVisualization::Get](#)
- [IDLitVisualization::GetCenterRotation](#)
- [IDLitVisualization::GetCurrentSelectionVisual](#)
- [IDLitVisualization::GetDataSpace](#)
- [IDLitVisualization::GetDataString](#)
- [IDLitVisualization::GetDefaultSelectionVisual](#)
- [IDLitVisualization::GetManipulatorTarget](#)
- [IDLitVisualization::GetProperty](#)
- [IDLitVisualization::GetRequestedAxesStyle](#)
- [IDLitVisualization::GetSelectionVisual](#)
- [IDLitVisualization::GetTypes](#)
- [IDLitVisualization::GetXYZRange](#)
- [IDLitVisualization::Init](#)
- [IDLitVisualization::Is3D](#)
- [IDLitVisualization::IsIsotropic](#)
- [IDLitVisualization::IsManipulatorTarget](#)
- [IDLitVisualization::IsSelected](#)
- [IDLitVisualization::Move](#)
- [IDLitVisualization::On2DRotate](#)

- `IDLitVisualization::OnAxesRequestChange`
- `IDLitVisualization::OnAxesStyleRequestChange`
- `IDLitVisualization::OnDataChange`
- `IDLitVisualization::OnDataComplete`
- `IDLitVisualization::OnDataRangeChange`
- `IDLitVisualization::OnDimensionChange`
- `IDLitVisualization::OnWorldDimensionChange`
- `IDLitVisualization::Remove`
- `IDLitVisualization::RequestsAxes`
- `IDLitVisualization::Restore`
- `IDLitVisualization::Rotate`
- `IDLitVisualization::Scale`
- `IDLitVisualization::Select`
- `IDLitVisualization::Set3D`
- `IDLitVisualization::SetAxesRequest`
- `IDLitVisualization::SetAxesStyleRequest`
- `IDLitVisualization::SetCurrentSelectionVisual`
- `IDLitVisualization::SetData`
- `IDLitVisualization::SetDefaultSelectionVisual`
- `IDLitVisualization::SetParameterSet`
- `IDLitVisualization::SetProperty`
- `IDLitVisualization::UpdateSelectionVisual`
- `IDLitVisualization::VisToWindow`
- `IDLitVisualization::WindowToVis`

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 6, “Creating a Visualization”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
6.1	Deprecated GROUP_PARENT property

For more information on deprecated features, see [Appendix I, “IDL API History”](#).

IDLitVisualization Properties

IDLitVisualization objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLitVisualization::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be initialized via [IDLitVisualization::Init](#). Properties with the word “Yes” in the “Set” column of the property table can be set via [IDLitVisualization::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [CENTER_OF_ROTATION](#)
- [IMPACTS_RANGE](#)
- [ISOTROPIC](#)
- [MANIPULATOR_TARGET](#)
- [PROPERTY_INTERSECTION](#)
- [SELECT_TARGET](#)
- [TYPE](#)

In addition, objects of this class inherit:

- [IDLgrModel](#)
- [IDLitIMessaging](#)
- [IDLitParameter](#)

CENTER_OF_ROTATION

A two- or three-element vector, $[x, y]$ or $[x, y, z]$ indicating the center (in data coordinates) of rotation for this visualization. If a two-element vector is supplied, the

z value remains unchanged. When retrieving the value of this property, the center of rotation is always returned as a three-element vector.

Property Type	Vector		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IMPACTS_RANGE

A boolean that, when set to 0, indicates that the x , y , and z range of the contents of this visualization should not impact the x , y , and z range of any visualization that contains it. By default, IMPACTS_RANGE is 1.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ISOTROPIC

A boolean that, when set to a non-zero value, indicates that this object should have isotropic scaling applied to it. By default, ISOTROPIC is 0 (isotropic scaling is not enforced).

Setting isotropic scaling to True implies that the dimensions of the visualization can be related to physical dimensions and that the ratio of the dimensions must be preserved. An example is an image, where the pixels are usually square and should remain square.

Setting isotropic scaling to False implies that the visualization dimensions do not relate to physical dimensions and that the ratio of the dimensions is arbitrary. An example is a plot, where the aspect ratio of the X and Y coordinates is arbitrary and can be changed for appearance's sake.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

MANIPULATOR_TARGET

A boolean that, when set to a non-zero value, indicates that this object should be treated as a target for manipulations. By default, MANIPULATOR_TARGET is 0 (this object is not a target for manipulations). Whenever selection changes in a tool, each manipulator is checked against the selected visualization, to verify that the manipulator is allowable for that visualization. The MANIPULATOR_TARGET setting is only used when the manipulator does not have its TYPES property set. If the manipulator has its TYPES set, then the type must match the selected visualization (or a parent of the visualization).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROPERTY_INTERSECTION

A boolean value that indicates whether the visualization should display the intersection or the union of the properties of any aggregated objects. Visualizations that display the union of their aggregated objects' properties appear in iTool browsers as a single visualization with one set of properties. Visualizations that display the intersection of their aggregated objects' properties appear in iTool browsers as a container for the aggregated objects, allowing access to the contained objects' properties as well as to those of the container. See [“Working with Aggregated Properties”](#) (Chapter 4, *iTool Developer's Guide*) for additional discussion of aggregated properties.

Property Type	Boolean		
Name String	<i>no default value</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

SELECT_TARGET

A Boolean value that tags the visualization object as the target object to be returned when any object contained by the visualization is selected via the [IDLitVisualization::Select](#) method.

- 0 = Do not tag the visualization object as the target object.
- 1 = Tag the visualization object as the target object (default).

This property is registered as a Boolean property, but it is hidden by default.

Property Type	Boolean		
Name String	Select target		
Get: Yes	Set: Yes	Init: Yes	Registered: Yes

TYPE

A string or vector of strings that identify the type(s) that this visualization represents. See [“Predefined iTool Visualization Classes”](#) (Chapter 6, *iTool Developer’s Guide*) for a list of predefined types.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

IDLitVisualization::Add

The IDLitVisualization::Add procedure method adds objects to the visualization container.

This method overrides the superclass [IDLgrModel::Add](#) method. This specialized implementation performs the following actions:

- Stores visualizations in the correct order based on type so that they are correctly displayed
- Adds the objects to appropriate positions
- Handles property aggregation (if the AGGREGATE keyword is set)
- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate
- Sends notification that the scene needs to be redrawn (unless the NO_UPDATE keyword is set)

Syntax

```
Obj->[IDLitVisualization::]Add, Objects [, /AGGREGATE] [, /NO_UPDATE]  
[, POSITION=index]
```

Arguments

Objects

An object reference (or array of object references), each referring to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be added to the visualization container.

Keywords

AGGREGATE

Set this keyword to indicate that the object(s) being added should become part of this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (accessible via the GetProperty and SetProperty methods). See [“Property Aggregation”](#) (Chapter 4, *iTool Developer's Guide*) for additional details.

NO_UPDATE

Set this keyword to indicate that the overall scene should not be updated after the addition of the object(s). By default, the overall scene is updated.

POSITION

Set this keyword equal to a scalar or vector of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within this visualization container at which the corresponding object should be placed. The default is to add new objects at the end of the list of contained items.

Version History

6.0	Introduced
6.1	Deprecated GROUP keyword

For more information on deprecated features, see [Appendix I, “IDL API History”](#).

IDLitVisualization::Aggregate

The IDLitVisualization::Aggregate procedure method adds the given object(s) to this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (via ::GetProperty and ::SetProperty).

See “[Property Aggregation](#)” (Chapter 4, *iTool Developer's Guide*) for additional details.

Syntax

Obj->[IDLitVisualization::](#)Aggregate, *Objects*

Arguments

Objects

An object reference (or array of object references), each of which refers to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be aggregated within this visualization container.

Keywords

None.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::BeginManipulation

The IDLitVisualization::BeginManipulation procedure method handles notifications that an [IDLitManipulator](#) object is about to manipulate this visualization.

Note

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in [“Predefined iTool Visualization Classes”](#) (Chapter 6, *iTool Developer’s Guide*)).

Syntax

Obj->[\[IDLitVisualization::\]BeginManipulation](#), *Manipulator*

Arguments

Manipulator

An object reference to the manipulator object sending notification.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::Cleanup

The IDLitVisualization::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitVisualization::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::EndManipulation

The IDLitVisualization::EndManipulation procedure method handles notifications that an [IDLitManipulator](#) object has finished manipulating this visualization.

Note

Calling this method on this visualization object simply returns without action. This method is designed to be implemented by a sub-class (such as those listed in [“Predefined iTool Visualization Classes”](#) (Chapter 6, *iTool Developer’s Guide*)).

Syntax

Obj->[\[IDLitVisualization::\]EndManipulation](#), *Manipulator*

Arguments

Manipulator

An object reference to the manipulator object sending notification.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::Get

The IDLitVisualization::Get function method retrieves object(s) from the visualization.

Syntax

```
Result = Obj->[IDLitVisualization::]Get([, /ALL] [, COUNT=variable]
    [, ISA=string or array of strings] [, POSITION=index or array of indices]
    [, /SKIP_PRIVATE])
```

Return Value

Returns the reference of the object retrieved from the visualization. If the object is not contained by this visualization, a NULL object reference is returned.

Arguments

None

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

SKIP_PRIVATE

Set this keyword to indicate that this method should return only those objects that do not have the PRIVATE property set.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetCenterRotation

The IDLitVisualization::GetCenterRotation function method returns the center of rotation for this visualization.

Syntax

```
Result = Obj->[IDLitVisualization:]GetCenterRotation([, /NO_TRANSFORM]  
[, XRANGE=[xmin, xmax]] [, YRANGE=[ymin, ymax]] [, ZRANGE=[zmin,  
zmax]])
```

Return Value

Returns a two- or three-element vector, $[x, y]$ or $[x, y, z]$ indicating the center (in data coordinates) of the bounding box for this visualization if the center of rotation was not explicitly specified with the CENTER_OF_ROTATION property of this visualization. See the [CENTER_OF_ROTATION](#) property for more details.

Arguments

None

Keywords

NO_TRANSFORM

Set this keyword to indicate that this visualization's transform should not be applied when computing the x , y , and z ranges. By default, the transform is applied.

XRANGE

Set this keyword to a named variable that will contain a 2-element vector, $[xmin, xmax]$, representing the x range of the bounding box for this visualization.

YRANGE

Set this keyword to a named variable that will contain a 2-element vector, $[ymin, ymax]$, representing the y range of the bounding box for this visualization.

ZRANGE

Set this keyword to a named variable that will contain a 2-element vector, $[zmin, zmax]$, representing the z range of the bounding box for this visualization.

Version History

6.0	Introduced
6.1	Deprecated DATA keyword

For more information on deprecated features, see [Appendix I, “IDL API History”](#).

IDLitVisualization::GetCurrentSelectionVisual

The IDLitVisualization::GetCurrentSelectionVisual function method returns the currently active selection visual object for this visualization.

Syntax

Result = *Obj*->[IDLitVisualization:]GetCurrentSelectionVisual()

Return Value

Returns a reference to an IDLitManipulatorVisual object. If no selection visual is currently active, the NULL object reference is returned.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetDataSpace

The IDLitVisualization::GetDataSpace function method returns a reference to the parent data space object within the graphics hierarchy that contains the visualization.

Syntax

Result = *Obj*->[IDLitVisualization::]GetDataSpace([, /UNNORMALIZED])

Return Value

Returns a reference to the nearest data space object in the graphics hierarchy. If no data space objects are found by walking up the hierarchy, then a null object reference is returned.

Arguments

None

Keywords

UNNORMALIZED

Set this keyword to indicate that the returned data space should be the parent data space that subclasses from the IDLitVisDataSpace class (which is not normalized) rather than the IDLitVisNormDataSpace class (which is normalized).

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetDataString

The IDLitVisualization::GetDataString function method retrieves a description of this visualization's data at the given x , y , and z location.

Note

This method is designed to be implemented as needed by subclasses. The IDLitVisualization::GetDataString method simply always returns an empty string

Syntax

Result = Obj->[IDLitVisualization::]GetDataString(XYZLocation)

Return Value

Returns a string describing the visualization's data at the given location.

Arguments

XYZLocation

A three-element vector representing the x , y , and z location of the data for which a string description is to be returned.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetDefaultSelectionVisual

The IDLitVisualization::GetDefaultSelectionVisual function method returns an object that serves as the default selection visual for this visualization.

Note

If the visualization on which this method is called is not a manipulator target (see “[MANIPULATOR_TARGET](#)” on page 5055), the default selection visual returned by this method will be used as the current selection visual whenever the visualization is selected.

Syntax

Result = *Obj*->[IDLitVisualization:]GetDefaultSelectionVisual()

Return Value

Returns a reference to an IDLitManipulatorVisual object.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetManipulatorTarget

The IDLitVisualization::GetManipulatorTarget function method retrieves the manipulator target associated with this visualization. The manipulator target may be this visualization itself.

Syntax

```
Result = Obj->[IDLitVisualization::]GetManipulatorTarget()
```

Return Value

Returns an object reference to the manipulator target, or a NULL object reference if none is found.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetProperty

The IDLitVisualization::GetProperty procedure method retrieves the value of a property or group of properties for the object.

Syntax

Obj->[IDLitVisualization::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 5053 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetRequestedAxesStyle

The IDLitVisualization::GetRequestedAxesStyle function method returns a scalar value indicating the axes style requested by this visualization. This method returns the axes style request made by the first visualization within the hierarchy (beginning with the root visualization) to make a request. If none of the visualizations in the hierarchy requests an axes style then -1 is returned.

Syntax

Result = *Obj*->[IDLitVisualization:]GetRequestedAxesStyle()

Return Value

Returns a scalar value indicating the requested axes style. Possible return values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 32-9: Axes Style Values

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::GetSelectionVisual

The IDLitVisualization::GetSelectionVisual function method retrieves the selection visual for this visualization that corresponds to the given manipulator.

Syntax

Result = *Obj*->[IDLitVisualization:]GetSelectionVisual(*Manipulator*)

Return Value

Returns a reference to an IDLitManipulatorVisual object that corresponds to the given manipulator. If this visualization already has a selection visual for the given manipulator, a reference to that selection visual is returned. Otherwise, a default selection visual will be requested from the manipulator, added to the visualization, and returned.

Arguments

Manipulator

Set this argument to a reference to an IDLitManipulator object that identifies the manipulator for which a selection visual is to be retrieved.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetTypes

The IDLitVisualization::GetTypes function method identifies the types that this visualization represents, including base types and any specializations.

Note

This method is designed to be implemented as needed by subclasses of the IDLitVisualization class. Calling this method on the IDLitVisualization class itself returns the following string array: ['VISUALIZATION', '_VISUALIZATION', *AnySpecifiedTypes*] where *AnySpecifiedTypes* are provided by any value set for the TYPE property of the IDLitVisualization class.

Syntax

Result = *Obj*->[IDLitVisualization:]GetTypes()

Return Value

Returns a vector of strings identifying the types that this visualization represents. See [“Predefined iTool Visualization Classes”](#) (Chapter 6, *iTool Developer’s Guide*) for a list of predefined types

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::GetXYZRange

The IDLitVisualization::GetXYZRange function method computes the x , y , and z ranges of the overall contents of the visualization, taking into account the IMPACTS_RANGE property setting for itself and its contents.

Syntax

```
Result = Obj->[IDLitVisualization::]GetXYZRange(XRange,YRange,ZRange  
[, /DATA] [, /NO_TRANSFORM])
```

Return Value

Returns a 1 if the x , y , and z ranges were successfully computed, or 0 otherwise.

Arguments

XRange

A named variable that, upon return, will contain a two-element vector, [$xmin$, $xmax$], representing the x -range of the contents of this visualization that impact ranges.

YRange

A named variable that, upon return, will contain a two-element vector, [$ymin$, $ymax$], representing the y -range of the contents of this visualization that impact ranges.

ZRange

A named variable that, upon return, will contain a two-element vector, [$zmin$, $zmax$], representing the z -range of the contents of this visualization that impact ranges.

Keywords

DATA

Set this keyword to indicate that the ranges should be computed for the full data sets of the contents of this visualization. By default, if the keyword is not set, the ranges are computed for the displayed portions of the data sets.

NO_TRANSFORM

Set this keyword to indicate that this visualization's transform matrix should not be applied when computing the x , y , and z ranges. By default, the transform matrix is applied.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::Init

The IDLitVisualization::Init function method initializes the visualization object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitVisualization' [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitVisualization::]Init( [, PROPERTY=value] ) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 5053 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::Is3D

The IDLitVisualization::Is3D function method determines whether or not this visualization is marked as being three-dimensional.

Syntax

Result = *Obj*->[IDLitVisualization::]Is3D()

Return Value

Returns 1 if this visualization is marked as being three-dimensional, or 0 if it is not three-dimensional.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::IsIsotropic

The IDLitVisualization::IsIsotropic function method indicates whether or not this visualization (or any of its contents) is marked as being isotropic. See the [ISOTROPIC](#) property for more information.

Syntax

Result = *Obj*->[IDLitVisualization::]IsIsotropic()

Return Value

Returns 1 if the visualization or any of the items it contains has the ISOTROPIC property set, or 0 otherwise.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::IsManipulatorTarget

The IDLitVisualization::IsManipulatorTarget function method determines whether or not this visualization is a manipulator target.

Syntax

Result = *Obj*->[IDLitVisualization::]IsManipulatorTarget()

Return Value

Returns 1 if this visualization is a manipulator target, or 0 if it is not.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::IsSelected

The IDLitVisualization::IsSelected function method determines if this visualization is currently selected or not.

Syntax

Result = *Obj*->[IDLitVisualization::]IsSelected()

Return Value

Returns 1 if this visualization is currently selected, or 0 if it is not selected.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::Move

The IDLitVisualization::Move procedure method moves an object from one position in the visualization container to a new position. Use the [IDLitVisualization::Get](#) method to return the objects within the visualization.

The positions of the objects within a container controls how they are rendered. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later.

Note

This method overrides the [IDL_Container::Move](#) method, which IDLitVisualization inherits since IDL_Container is a superclass of IDLgrModel. This specialized implementation of the Move method ensures visualizations are stored in the correct order based on type when they are moved. Those items that must appear on top of other objects are stored as the last items in the list of objects contained by this visualization.

Syntax

Obj->[IDLitVisualization::]Move, *Source*, *Destination*

Arguments

Source

The zero-based index of the current location of the object to be moved.

Destination

The zero-based index of the new location where the object will reside after being moved.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::On2DRotate

The IDLitVisualization::On2DRotate procedure method notifies objects that use the visualization's data when the rotation of the parent dataspace changes.

Syntax

Obj->[IDLitVisualization::]On2DRotate, *Notifier*, *IsRotated*

Arguments

Notifier

An object reference to the parent object that is sending notification when the dataspace rotation changes.

IsRotated

A scalar value that is non-zero if the dataspace is now rotated, or zero otherwise.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::OnAxesRequestChange

The IDLitVisualization::OnAxesRequestChange procedure method notifies objects that use the visualization's data when the axes of a contained object change.

Syntax

Obj->[IDLitVisualization::]OnAxesRequestChange, *Notifier*, *AxesRequest*

Arguments

Notifier

An object reference to the object that is sending notification when axes change.

AxesRequest

A scalar value representing the new axes request. Allowable values are:

Value	Requested Axes
0	No axes requested.
1	Axes requested.
2	Axes should be automatically computed.

Table 32-10: Allowable AxesRequest Values

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::OnAxesStyleRequestChange

The IDLitVisualization::OnAxesStyleRequestChange procedure method notifies objects that use the visualization's data when the axes style of a contained object changes.

Syntax

Obj->[IDLitVisualization::]OnAxesStyleRequestChange, *Notifier*, *StyleRequest*

Arguments

Notifier

An object reference to the object that is sending notification when the axes style changes.

StyleRequest

A scalar value representing the new axes style request. Allowable values are:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested axes.

Table 32-11: Axes Style Values

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::OnDataChange

The IDLitVisualization::OnDataChange procedure method notifies objects that use the visualization's data when the visualization's data changes.

Note

This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataChange, *Notifier*

Arguments

Notifier

A reference to the object that is sending notification when the data changes.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::OnDataComplete

The IDLitVisualization::OnDataComplete procedure method notifies objects that use the visualization's data when changes to the visualization's data are complete.

Note

This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::]OnDataComplete, *Notifier*

Arguments

Notifier

A reference to the object that is sending notification when the data changes are complete.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::OnDataRangeChange

The IDLitVisualization::OnDataRangeChange procedure method notifies objects that use the visualization's data when the range of the visualization's data changes.

Note

This method is generally not called explicitly.

Syntax

Obj->[IDLitVisualization::](#)OnDataRangeChange, *Notifier*, *XRange*, *YRange*, *Zrange*

Arguments

Notifier

A reference to the object that is sending notification when the data range changes.

XRange

A two-element vector, [*xmin*, *xmax*], representing the new *x*-range.

YRange

A two-element vector, [*ymin*, *ymax*], representing the new *y*-range.

ZRange

A two-element vector, [*zmin*, *zmax*], representing the new *z*-range.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::OnDimensionChange

The IDLitVisualization::OnDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's data changes.

Syntax

Obj->[IDLitVisualization::]OnDimensionChange, *Notifier*, *Is3D*

Arguments

Notifier

An object reference to the object that is sending notification when the dimensionality changes.

Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::OnWorldDimensionChange

The IDLitVisualization::OnWorldDimensionChange procedure method notifies objects that use the visualization's data when the dimensionality of the visualization's parent dataspace changes.

Syntax

Obj->[IDLitVisualization::]OnWorldDimensionChange, *Notifier*, *Is3D*

Arguments

Notifier

An object reference to the parent object that is sending notification when the dimensionality changes.

Is3D

A scalar value that is non-zero if the object is now three-dimensional, or zero otherwise.

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::Remove

The IDLitVisualization::Remove procedure method removes the given object(s) from the visualization.

This method overrides the [IDL_Container::Remove](#) method, which IDLitVisualization inherits since IDL_Container is a superclass of IDLgrModel. This specialized implementation of the Remove method performs the following actions:

- Handles property aggregation
- Updates this visualization's state flags (indicating whether this visualization is 3-D, isotropic, etc.) as appropriate
- Sends notification that the scene needs to be redrawn (unless the NO_UPDATE keyword is set)

Syntax

Obj->[IDLitVisualization::]Remove, *Object* [, /NO_UPDATE]

Arguments

Object

A reference (or vector of references) to the object(s) to be removed from this visualization.

Keywords

NO_UPDATE

Set this keyword to indicate the scene should not be updated after objects are removed. By default, the overall scene is updated.

Version History

6.0	Introduced
6.1	Added NO_UPDATE keyword

IDLitVisualization::RequestsAxes

The IDLitVisualization::RequestsAxes function method indicates whether or not the visualization requests axes. Most visualization classes do request axes. However, axes, images, ROIs, map grids, profile lines, and backgrounds do not request axes.

Syntax

Result = *Obj*->[IDLitVisualization:]RequestsAxes()

Return Value

Returns a 1 if the visualization does request axes, or 0 if does not request axes.

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

IDLitVisualization::Restore

The IDLitVisualization::Restore procedure method performs any transitional work required after an object of this class has been restored from a SAVE file, to ensure that its state is appropriate for the current version.

Note

This method overrides the implementation in the IDLitComponent class. This specialized implementation ensures that all axes requests and axis style requests are set properly.

Syntax

Obj->[IDLitVisualization::]Restore

Arguments

None

Keywords

None

Version History

6.1	Introduced
-----	------------

See Also

[IDL_Savefile](#), [SAVE](#), [RESTORE](#)

IDLitVisualization::Rotate

The IDLitVisualization::Rotate procedure method rotates this visualization about the given axis by the given angle.

This method overrides the superclass's [IDLgrModel::Rotate](#) method. This specialized implementation rotates about a center of rotation rather than about the origin, [0,0,0].

Syntax

```
Obj->[IDLitVisualization::]Rotate, Axis, Angle [, CENTER_OF_ROTATION=[x, y, z]] [, /PREMULTIPLY]
```

Arguments

Axis

A three-element vector of the form [x, y, z] describing the axis about which the visualization is to be rotated.

Angle

A scalar value indicating the angle of rotation (measured in degrees).

Keywords

CENTER_OF_ROTATION

Set this keyword to a three-element vector, [x, y, z], representing the center of the rotation. By default, the visualization's own center of rotation (accessible through "[IDLitVisualization::GetCenterRotation](#)" on page 5065) will be used.

PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to this visualization's current transformation matrix. By default, the rotation matrix is post-multiplied.

Note

In pre-multiplication, the current visualization's transform and scaling are applied before the specified rotation. In post-multiplication, the specified rotation is applied before the visualization's transformation and scaling.

Version History

6.1	Introduced
-----	------------

IDLitVisualization::Scale

The IDLitVisualization::Scale procedure method scales the visualization by the given scale factors.

Syntax

```
Obj->[IDLitVisualization::]Scale, SX, SY, SZ [, CENTER_OF_ROTATION=[x, y] |  
[x, y, z]] [, /PREMULTIPLY]
```

Arguments

SX

The factor in the x -dimension by which the visualization is to be scaled.

SY

The factor in the y -dimension by which the visualization is to be scaled.

SZ

The factor in the z -dimension by which the visualization is to be scaled.

Keywords

CENTER_OF_ROTATION

Set this keyword to a 2- or 3-element vector, $[x, y]$ or $[x,y,z]$, representing the center of rotation (in data coordinates) to be used as the center for scaling. By default, if PREMULTIPLY is set, then this visualization's own center of rotation will be used as the center for scaling; if PREMULTIPLY is not set, the result of transforming this visualization's center of rotation by its own transformation matrix will be used as the center for scaling.

PREMULTIPLY

Set this keyword to cause the scaling matrix specified by S_x , S_y , and S_z to be pre-multiplied to this visualization's transformation matrix. By default, the scaling matrix is post-multiplied.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::Select

The IDLitVisualization::Select procedure method handles notification of mechanisms that key off the current selection (such as the visualization browser) when this visualization has been selected.

Syntax

```
Obj->[IDLitVisualization::]Select[, Mode]  
    [, /ADDITIVE | /SELECT | /TOGGLE | /UNSELECT] [, /NO_NOTIFY]
```

Arguments

Mode

A scalar that indicates the selection mode. Valid values include:

- 0 - Unselect (deselect this visualization).
- 1 - Select (set this visualization as the current selection). This mode is the default.
- 2 - Toggle (toggle the selection of this visualization). Use the **CRTL** key to toggle.
- 3 - Additive (add this visualization to the current selection list). Use the **SHIFT** key to add.

Keywords

ADDITIVE

Set this keyword to indicate that the selection mode is additive. This is equivalent to setting *Mode* to 3.

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of this selection. By default, the parent is notified.

SELECT

Set this keyword to indicate that the selection mode is select. This is equivalent to setting *Mode* to 1.

TOGGLE

Set this keyword to indicate that the selection mode is toggle. This is equivalent to setting *Mode* to 2.

UNSELECT

Set this keyword to indicate that the selection mode is unselect. This is equivalent to setting *Mode* to 0.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::Set3D

The IDLitVisualization::Set3D procedure method sets a flag indicating this visualization is three-dimensional.

Syntax

```
Obj->[IDLitVisualization::]Set3D, Is3D [, /ALWAYS] [, /AUTO_COMPUTE]
```

Arguments

Is3D

A non-zero value indicates that the visualization is three-dimensional; 0 indicates that it is two-dimensional.

Keywords

ALWAYS

Set this keyword to indicate that the given 3-D setting always applies.

AUTO_COMPUTE

Set this keyword to indicate that the 3-D setting for this visualization should be auto-computed based upon the dimensionality of its contents. This keyword is mutually exclusive of the ALWAYS keyword, and the *Is3D* argument is ignored if AUTO_COMPUTE is set.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::SetAxesRequest

The IDLitVisualization::SetAxesRequest procedure method sets the current axes request for this visualization.

Syntax

```
Obj->[IDLitVisualization::]SetAxesRequest [, AxesRequest]  
[, /ALWAYS | /AUTO_COMPUTE] [, /NO_NOTIFY]
```

Arguments

AxesRequest

A scalar value indicating whether this visualization requests axes:

- 0 – Axes are not requested by the visualization
- 1 – Axes are requested by the visualization.

Note

If this argument is not present, the visualization is marked as requesting axes.

Keywords

ALWAYS

Set this keyword to always request or not request axes as specified by the *AxesRequest* argument. This setting will override the requests made by children of the visualization.

AUTO_COMPUTE

Set this keyword to compute the axes for this visualization based on the axes requested by objects contained in the visualization.

Note

This keyword is mutually exclusive of the ALWAYS keyword. If this keyword is set, the *AxesRequest* argument is ignored.

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in axes request. By default, the parent is notified.

Version History

6.1	Introduced
-----	------------

IDLitVisualization::SetAxesStyleRequest

The IDLitVisualization::SetAxesStyleRequest procedure method sets the current axes style request for this visualization. The axes container is automatically created whenever a data space is instantiated, but the default axes style property is 0 (None) until visualizations are added.

Whenever a visualization is added to the visualization container, it is queried for axes requirements. Most visualization classes do request axes (with the exception of axes, images, ROIs, map grids, profile lines, and backgrounds). When visualizations are added, and the current axes style value is 0 (None), then the axes style will be changed as follows:

- The axes style is set according to the request of the first visualization in the hierarchy to request a *particular* axes style. By default, most visualizations do not request a particular style. The exceptions are plots, which request style 2 (Box Axes) if non-polar, or style 3 (Crosshairs) if polar.
- The default style 1 (At Dataspace Minimum) is used if none of the visualizations in the hierarchy request a particular axes style.

Syntax

Obj->[IDLitVisualization::]SetAxesStyleRequest, *StyleRequest* [, /NO_NOTIFY]

Arguments

StyleRequest

A scalar value representing the requested axes style. The value should correspond to one of the values listed in the following table:

Value	Requested Axes Style
0	None.
1	At Dataspace Minimum.
2	Box Axes.
3	Crosshairs.
-1	No visualization in the hierarchy requested a particular axes style.

Table 32-12: Axes Style Values

Keywords

NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of a change in the axes style request. By default, the parent is notified.

Version History

6.1	Introduced
-----	------------

IDLitVisualization::SetCurrentSelectionVisual

The IDLitVisualization::SetCurrentSelectionVisual procedure method sets the current selection visual for the given manipulator.

Syntax

Obj->[IDLitVisualization::]SetCurrentSelectionVisual, *Manipulator*

Arguments

Manipulator

An object reference (that subclasses from IDLitManipulator) identifying the manipulator that corresponds to the selection visual to be set as current.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::SetData

The IDLitVisualization::SetData function method sets the data parameter of the visualization.

Note

If the SetData method returns successfully, notification of a data change is issued to all observers of the data object.

Syntax

Result = Obj->[IDLitVisualization::]SetData(*Data*)

Return Value

Returns a 1 if successful, or 0 if it fails.

Arguments

Data

A reference to the data object to be associated with the visualization parameter.

Keywords

This method accepts all keywords accepted by the IDLitParameter::SetData method.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::SetDefaultSelectionVisual

The IDLitVisualization::SetDefaultSelectionVisual procedure method sets the default selection visual to be associated with this visualization.

Note

If the visualization on which this method is called is not a manipulator target (see “[MANIPULATOR_TARGET](#)” on page 5055) the default selection visual set by this method will be used as the current selection visual whenever the visualization is selected.

Syntax

```
Obj->[IDLitVisualization::]SetDefaultSelectionVisual, SelectionVisual
[, POSITION=value]
```

Arguments

SelectionVisual

A reference to the IDLitManipulatorVisual object that is added to the visualization object and serves as the default selection visual for this visualization.

Keywords

POSITION

Set this keyword equal to the zero-based position at which the selection visual should be inserted within the container. The default is to add the object to the end of the container (the visualization object).

Version History

6.0	Introduced
-----	------------

IDLitVisualization::SetParameterSet

The IDLitVisualization::SetParameterSet function method associates a parameter set with this visualization.

Note

If the SetParameterSet method returns successfully, notification of a data change is issued to all observers of the visualization's data.

Syntax

Result = Obj->[IDLitVisualization::]SetParameterSet(*ParameterSet*)

Return Value

Returns a 1 if successful, or a 0 otherwise.

Arguments

ParameterSet

A reference to the IDLitParameterSet object to be associated with the visualization.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization:: SetProperty

The IDLitVisualization:: SetProperty procedure method sets the value of a property or group of properties for the object.

Syntax

Obj->[IDLitVisualization::] SetProperty[, *PROPERTY=value*]

Arguments

None

Keywords

Any property listed under “[IDLitVisualization Properties](#)” on page 5053 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::UpdateSelectionVisual

The IDLitVisualization::UpdateSelectionVisual procedure method transforms this visualization's selection visual to match the visualization's geometry.

Syntax

Obj->[IDLitVisualization::](#)UpdateSelectionVisual

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitVisualization::VisToWindow

The IDLitVisualization::VisToWindow procedure method transforms given points from visualization data space to window device coordinates.

Syntax

```
Obj->[IDLitVisualization::]VisToWindow, InX, InY, InZ, OutX, OutY, OutZ  
    [, /NO_TRANSFORM]
```

or

```
Obj->[IDLitVisualization::]VisToWindow, InX, InY, OutX, OutY  
    [, /NO_TRANSFORM]
```

or

```
Obj->[IDLitVisualization::]VisToWindow, InVerts, OutVerts [, /NO_TRANSFORM]
```

Arguments

InX

A vector of input X values (in visualization data space).

InY

A vector of input Y values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

InZ

A vector of input Z values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

InVerts

A [2, *n*] or [3, *n*] array of input vertices (in visualization data space).

OutX

A named variable that will contain a vector of output X values (in window device coordinates).

OutY

A named variable that will contain a vector of output Y values (in window device coordinates).

OutZ

A named variable that will contain a vector of output Z values (in window device coordinates).

OutVerts

A named variable that will contain a vector of output vertices (in window device coordinates).

Keywords

NO_TRANSFORM

If this keyword is set, the current transformation matrix is not included in the computation. Setting this keyword is useful when computing selection visual scaling.

Version History

6.0	Introduced
-----	------------

IDLitVisualization::WindowToVis

The IDLitVisualization::WindowToVis procedure method transforms given points from window device coordinates to visualization data space.

Syntax

Obj->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *InZ*, *OutX*, *OutY*, *OutZ*

or

Obj->[IDLitVisualization::]WindowToVis, *InX*, *InY*, *OutX*, *OutY*

or

Obj->[IDLitVisualization::]WindowToVis, *InVerts*, *OutVerts*

Arguments

InX

A vector representing the input x values (in window device coordinates).

InY

A vector representing the input y values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

InZ

A vector representing the input z values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

InVerts

A [2, *n*] or [3, *n*] array representing the input vertices (in window device coordinates).

OutX

A named variable that upon return will contain a vector representing the output x values (in visualization data space).

OutY

A named variable that upon return will contain a vector representing the output y values (in visualization data space).

OutZ

A named variable that upon return will contain a vector representing the output z values (in visualization data space).

OutVerts

A named variable that upon return will contain a vector representing the output vertices (in visualization data space).

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow

The IDLitWindow class serves as the base class for all windows within the iTools framework.

Superclasses

[IDLgrWindow](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitWindow::Init](#)” on page 5133.

Properties

Objects of this class inherit properties from the IDLgrWindow superclass. See “[IDLgrWindow Properties](#)” on page 4586 for descriptions of these properties.

Methods

This class has the following methods:

- [IDLitWindow::Add](#)
- [IDLitWindow::AddWindowEventObserver](#)
- [IDLitWindow::Cleanup](#)
- [IDLitWindow::ClearSelections](#)
- [IDLitWindow::DoHitTest](#)
- [IDLitWindow::GetEventMask](#)
- [IDLitWindow::GetProperty](#)
- [IDLitWindow::GetSelectedItems](#)
- [IDLitWindow::Init](#)
- [IDLitWindow::OnEnter](#)

- [IDLitWindow::OnExit](#)
- [IDLitWindow::OnExpose](#)
- [IDLitWindow::OnKeyboard](#)
- [IDLitWindow::OnMouseDown](#)
- [IDLitWindow::OnMouseMove](#)
- [IDLitWindow::OnMouseUp](#)
- [IDLitWindow::OnResize](#)
- [IDLitWindow::OnScroll](#)
- [IDLitWindow::OnTimer](#)
- [IDLitWindow::OnWheel](#)
- [IDLitWindow::Remove](#)
- [IDLitWindow::RemoveWindowEventObserver](#)
- [IDLitWindow::SetCurrentZoom](#)
- [IDLitWindow::SetEventMask](#)
- [IDLitWindow::SetManipulatorManager](#)
- [IDLitWindow::SetProperty](#)
- [IDLitWindow::SetTimerInterval](#)
- [IDLitWindow::ZoomIn](#)
- [IDLitWindow::ZoomOut](#)

In addition, this class inherits the methods of its superclass.

Version History

6.0	Introduced
6.2	Added <code>OnTimer</code> and <code>SetTimerInterval</code> methods
6.3	Added <code>OnEnter</code> , <code>OnExit</code> , <code>OnExpose</code> , and <code>OnResize</code> methods
6.4	Added <code>OnWheel</code> method

IDLitWindow Properties

IDLitWindow objects inherit properties from the IDLgrWindow superclass. See [“IDLgrWindow Properties”](#) on page 4586 for descriptions of these properties.

Properties with the word “Yes” in the “Get” column of the table can be retrieved via [IDLitWindow::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLitWindow::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLitWindow::SetProperty](#).

IDLitWindow::Add

The IDLitWindow::Add procedure method adds the given object(s) to the window.

Syntax

Obj->[IDLitWindow::]Add, *Objects* [, POSITION=*value*]

Arguments

Objects

A reference (or array of references) to the object(s) to be added to the window. Any of the objects that inherit from IDLgrViewGroup are added directly to the window's scene, which represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window. The remaining objects are added to the current view within the window's scene.

Keywords

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the position within the container at which the new object should be placed.

Version History

6.0	Introduced
-----	------------

IDLitWindow::AddWindowEventObserver

The `IDLitWindow::AddWindowEventObserver` procedure method adds the given object(s) to the list of observers that are to be notified of events that occur within the window. Each observer must implement one or more methods corresponding to bits in the `IDLitWindow` object's event mask, as set by the `IDLitWindow::SetEventMask` method:

Bit	Value	Event Type	Required Methods
0	1	Button Events	OnMouseDown OnMouseUp
1	2	Motion Events	OnMouseMotion
2	4	Keyboard Events	OnKeyboard
3	8	Tracking Events	<i>n/a</i>
4	16	Timer Events	OnTimer
5	32	Wheel Events	OnWheel

Table 32-13: Event Mask values and their corresponding methods

Note

See “[Designing a Behavior Object](#)” (Chapter 10, *Object Programming*) for examples that implement the `OnTimer` event in an animation display.

When an event occurs within this window, the corresponding method (from the list above) will be called for each observer in the window's list.

See the `IDLitWindow` methods of the same name for information on creating window observer methods.

Syntax

Obj->[[IDLitWindow::](#)]AddWindowEventObserver, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be added as window event observers.

Keywords

None

Version History

6.0	Introduced
-----	------------

See Also

[IDLitWindow::OnKeyboard](#), [IDLitWindow::OnMouseDown](#),
[IDLitWindow::OnMouseMotion](#), [IDLitWindow::OnMouseUp](#),
[IDLitWindow::OnTimer](#), [IDLitWindow::OnWheel](#), [IDLitWindow::SetEventMask](#)

IDLitWindow::Cleanup

The IDLitWindow::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitWindow::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow::ClearSelections

The IDLitWindow::ClearSelections procedure method clears the window's list of currently selected items (within its current view). The items within the current view that had been selected are deselected.

Syntax

Obj->[IDLitWindow::](#)ClearSelections

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow::DoHitTest

The IDLitWindow::DoHitTest function method performs a hit test to determine which visualizations within the destination are displayed at a given pixel location.

Note

The objects returned in *Result* are the “top-level” objects (usually IDLgrModel or IDLitVisualization objects). Objects *contained* by the returned objects can be returned using the SUB_HIT keyword.

Syntax

```
Result = Obj->[IDLitWindow::]DoHitTest(X, Y [, DIMENSIONS=[width, height]]
    [, /ORDER] [, SUB_HIT=variable] [, UNITS={0 | 1 | 2 | 3}])
```

Return Value

Returns a vector of references to the objects (usually IDLgrModel or IDLitVisualization objects) that appear at the given location. If no visualizations are displayed at that location, a null reference is returned.

Arguments

X

A floating-point value representing the *x*-location at which the hit test is to be performed

Y

A floating-point value representing the *y*-location at which the hit test is to be performed.

Keywords

DIMENSIONS

Set this keyword to a two-element integer vector, [*w*, *h*], to specify the dimensions (width and height) of the hit test box. The hit test box is centered at the location specified by the *X* and *Y* arguments. Any object that falls within this hit test box will be included in the return vector. By default, the hit test box is 3 pixels by 3 pixels.

ORDER

Set this keyword to control the ordering of objects in the returned hit test list when the objects are at the same distance from the viewer. Set ORDER=0 (the default) to return the objects in the order in which they were drawn. Set ORDER=1 to return objects in the reversed order from which they were drawn.

Note

If the visualization objects use DEPTH_TEST_FUNCTION=4 (less than or equal), then it is recommended that the ORDER keyword be set to 1 to ensure that objects at the same depth are returned in the same order in which they appear visually.

SUB_HIT

Set this keyword to a named variable that will contain references to all *contained* visualization objects that satisfy all of the following conditions:

- The objects are contained by the nearest hit visualization (the first object in the return value)
- The objects are SELECT_TARGETs (see “[IDLgrModel](#)” on page 4068)
- The objects are actively displayed at the given *X* and *Y* coordinates

The results of SUB_HIT are returned in the order in which the sub-hit visualizations appear in the graphics hierarchy. Sub-hits are only returned for the first visualization.

UNITS

Set this keyword to a scalar value to indicate the units of measure for the *X*, *Y* arguments and the DIMENSIONS keyword. Valid values include:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the primary monitor/screen, as stored in the SCREEN_DIMENSIONS property

Version History

6.0	Introduced
6.1	Added ORDER keyword

IDLitWindow::GetEventMask

The IDLitWindow::GetEventMask function method returns a bitwise mask representing the events that are enabled for this window.

Syntax

```
Result = Obj->[IDLitWindow::]GetEventMask([, BUTTON_EVENTS=variable]
[, KEYBOARD_EVENTS=variable] [, MOTION_EVENTS=variable]
[, TIMER_EVENTS=variable] [, TRACKING_EVENTS=variable]
[, WHEEL_EVENTS=variable])
```

Return Value

Returns the bitwise mask as an unsigned long integer. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events
4	16	Timer Events
5	32	Wheel Events

Table 32-14: Bits of the Event Mask

Arguments

None

Keywords

BUTTON_EVENTS

Set this keyword equal to a named variable that will contain a 1 if mouse button events are currently enabled for this window, or a 0 otherwise.

KEYBOARD_EVENTS

Set this keyword equal to a named variable that will contain a 1 if keyboard events are currently enabled for this window, or a 0 otherwise.

MOTION_EVENTS

Set this keyword equal to a named variable that will contain a 1 if mouse motion events are currently enabled for this window, or a 0 otherwise.

TIMER_EVENTS

Set this keyword equal to a named variable that will contain a 1 if timer events are currently enabled for this window, or a 0 otherwise.

TRACKING_EVENTS

Set this keyword equal to a named variable that will contain a 1 if tracking events are currently enabled for this window, or a 0 otherwise.

WHEEL_EVENTS

Set this keyword equal to a named variable that will contain a 1 if wheel events are currently enabled for this window, or a 0 otherwise.

Version History

6.0	Introduced
6.2	Added TIMER_EVENTS keyword
6.4	Added WHEEL_EVENTS keyword

IDLitWindow::GetProperty

The IDLitWindow::GetProperty procedure method retrieves the value of an IDLitWindow property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

Syntax

Obj->[IDLitWindow::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 5120 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitWindow::GetSelectedItems

The IDLitWindow::GetSelectedItems function method returns the objects (visualizations only, by default) currently selected within this window's scene.

Syntax

Result = *Obj*->[IDLitWindow::]GetSelectedItems([, /ALL] [, COUNT=*named variable*])

Return Value

Returns a vector of references to the objects currently selected within this window's scene. If no objects are currently selected, this function returns a -1.

Arguments

None

Keywords

ALL

Set this keyword to return all classes of selected items. By default, only visualizations are returned.

COUNT

Set this keyword to a named variable that will contain the number of items returned by this method.

Version History

6.0	Introduced
6.1	Added ALL keyword

IDLitWindow::Init

The IDLitWindow::Init function method initializes the window object.

This function method initializes the IDLitWindow object, and should be called by the subclass's Init method. This method also calls the superclass's Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDLitWindow'[, PROPERTY=value])
```

or

```
Result = Obj->[IDLitWindow::]Init([, PROPERTY=value]) (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

None

Keywords

Any property listed under “[IDLitWindow Properties](#)” on page 5120 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitWindow::OnEnter

[Syntax](#) | [Arguments](#) | [Keywords](#) | [Version History](#)

The IDLitWindow::OnEnter procedure method handles notification from the window that a mouse enter event has occurred.

Note

This method is only a stub and provides no functionality. In your subclass of IDLitWindow, you should override this method to provide your own functionality. Your method will be automatically called when a mouse enter event occurs.

Syntax

Obj->[IDLitWindow::]OnEnter

Arguments

IDLitWindow::OnExpose

[Syntax](#) | [Arguments](#) | [Keywords](#) | [Version History](#)

The IDLitWindow::OnExpose procedure method handles notification from the window that an expose event has occurred.

Note

By default, the OnExpose method will automatically redraw the graphics hierarchy. If you are using a subclass of IDLitWindow and require additional functionality, you should override this method. Your method will be automatically called when an expose event occurs.

Syntax

Obj->[IDLitWindow::]OnExpose, *X*, *Y*, *Width*, *Height*

Arguments

X

A floating-point value representing the *x*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Y

A floating-point value representing the *y*-coordinate of the lower left corner of the newly exposed portion of the canvas (in device coordinates).

Width

A floating-point value representing the width of the newly exposed portion of the canvas (in device coordinates).

Height

A floating-point value representing the height of the newly exposed portion of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitWindow::OnKeyboard

The `IDLitWindow::OnKeyboard` procedure method handles notification (from the native window device) that a keyboard event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the `IDLitWindow::AddWindowEventObserver` method). You can also *simulate* a keyboard event by calling this method directly.

Note

Window event observers that handle keyboard events *must* implement the `OnKeyboard` method, as described in “[Implementing the OnKeyboard Interface](#)” on page 5141. In addition, window event observers must implement the `OnMouseDown`, `OnMouseMove`, and `OnMouseUp` methods. See `IDLitWindow::AddWindowEventObserver` for details.

Syntax

Obj->[`IDLitWindow::`]OnKeyboard, *IsASCII*, *Character*, *KeySymbol*, *X*, *Y*, *Press*,
Release, *Modifiers*

Arguments

IsASCII

A scalar byte value that indicates whether the keyboard event corresponds to a character in the ASCII character set. If *IsASCII* is non-zero, the *Character* argument will be set to that ASCII character. If *IsASCII* is zero, the *KeySymbol* argument will be set to a numeric value indicating the key that was pressed.

Character

If *IsASCII* is non-zero, this argument is set to a byte value containing the ASCII character that corresponds to the key that was pressed. Otherwise, this argument is set to zero.

KeySymbol

If *IsASCII* is zero, this argument is set to a long integer that indicates the key that was pressed. Otherwise, this argument is set to zero. Valid values for key symbols include:

1	Shift
2	Control
3	Caps Lock
4	Alt
5	Left
6	Right
7	Up
8	Down
9	Page Up
10	Page Down
11	Home
12	End

X,Y

Long integers containing the *x*-coordinate and *y*-coordinate of the mouse cursor (in device coordinates) at the time of the event.

Press

A long integer indicating whether this event represents a key press. This argument is non-zero if the event is the result of pressing the key.

Release

A long integer indicating whether this event represents a key release. This argument is non-zero if the event is the result of releasing the key.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the keyboard event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-15: Modifier Values

Keywords

None

Implementing the OnKeyboard Interface

When defining a window event observer that handles keyboard events, you must implement an `OnKeyboard` procedure method with the following signature:

```
PRO OnKeyboard, Window, IsASCII, Character, KeySymbol, X, Y, $
    Press, Release, Modifiers
```

where the *Window* argument is an object reference to the `IDLitWindow` object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement `OnMouseDown`, `OnMouseMove`, and `OnMouseUp` procedure methods, as discussed in [“IDLitWindow::AddWindowEventObserver”](#) on page 5122.

Version History

6.0	Introduced
6.1	Corrected syntax to read <i>IsASCII</i> instead of <i>IsAlphaNumeric</i> Corrected <i>KeySymbol</i> values Added <i>X</i> , <i>Y</i> , <i>Press</i> , <i>Release</i> , <i>Modifiers</i> arguments

See Also

[IDLitWindow::AddWindowEventObserver](#), [IDLitWindow::OnMouseDown](#),
[IDLitWindow::OnMouseMove](#), [IDLitWindow::OnMouseUp](#)

IDLitWindow::OnMouseDown

The `IDLitWindow::OnMouseDown` procedure method handles notification (from the native window device) that a mouse down event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the [IDLitWindow::AddWindowEventObserver](#) method). You can also *simulate* a mouse down event by calling this method directly.

Note

Window event observers that handle mouse down events *must* implement the `OnMouseDown` method, as described in “[Implementing the OnMouseDown Interface](#)” on page 5144. In addition, window event observers must implement the `OnKeyboard`, `OnMouseMotion`, and `OnMouseUp` methods. See [IDLitWindow::AddWindowEventObserver](#) for details.

Syntax

Obj->[[IDLitWindow::](#)]OnMouseDown, *X*, *Y*, *ButtonMask*, *Modifiers*, *NumClicks*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was pressed:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 32-16: Bitmask for Button Events

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-17: Bits of the Modifier Key Mask

NumClicks

An integer indicating the number of times the mouse button was clicked.

Keywords

None

Implementing the OnMouseDown Interface

When defining a window event observer that handles mouse down events, you must implement an `OnMouseDown` procedure method with the following signature:

```
PRO OnMouseDown, Window, X, Y, ButtonMask, Modifiers, NumClicks
```

where the *Window* argument is an object reference to the `IDLitWindow` object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement `OnKeyboard`, `OnMouseMove`, and `OnMouseUp` procedure methods, as discussed in “[IDLitWindow::AddWindowEventObserver](#)” on page 5122.

Version History

6.0	Introduced
-----	------------

See Also

[IDLitWindow::AddWindowEventObserver](#), [IDLitWindow::OnKeyboard](#),
[IDLitWindow::OnMouseMotion](#), [IDLitWindow::OnMouseUp](#)

IDLitWindow::OnMouseMotion

The `IDLitWindow::OnMouseMotion` procedure method handles notification (from the native window device) that a mouse motion event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the [IDLitWindow::AddWindowEventObserver](#) method). You can also *simulate* a mouse motion event by calling this method directly.

Note

Window event observers that handle mouse motion events *must* implement the `OnMouseMotion` method, as described in “[Implementing the OnMouseMotion Interface](#)” on page 5147. In addition, window event observers must implement the `OnKeyboard`, `OnMouseDown`, and `OnMouseUp` methods. See [IDLitWindow::AddWindowEventObserver](#) for details.

Syntax

Obj->[IDLitWindow::]OnMouseMotion, X, Y, Modifiers

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control

Table 32-18: Bits of the Modifier Key Mask

Bit	Value	Modifier Key
2	4	Caps Lock
3	8	Alt

Table 32-18: Bits of the Modifier Key Mask

Keywords

None

Implementing the OnMouseMotion Interface

When defining a window event observer that handles mouse motion events, you must implement an `OnMouseMotion` procedure method with the following signature:

```
PRO OnMouseMotion, Window, X, Y, Modifiers
```

where the *Window* argument is an object reference to the `IDLitWindow` object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement `OnKeyboard`, `OnMouseDown`, and `OnMouseUp` procedure methods, as discussed in “[IDLitWindow::AddWindowEventObserver](#)” on page 5122.

Version History

6.0	Introduced
-----	------------

See Also

[IDLitWindow::AddWindowEventObserver](#), [IDLitWindow::OnKeyboard](#), [IDLitWindow::OnMouseDown](#), [IDLitWindow::OnMouseUp](#)

IDLitWindow::OnMouseUp

The `IDLitWindow::OnMouseUp` procedure method handles notification (from the native window device) that a mouse up event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the `IDLitWindow::AddWindowEventObserver` method). You can also *simulate* a mouse up event by calling this method directly.

Note

Window event observers that handle mouse up events *must* implement the `OnMouseUp` method, as described in “[Implementing the OnMouseUp Interface](#)” on page 5149. In addition, window event observers must implement the `OnKeyboard`, `OnMouseDown`, and `OnMouseMove` methods. See [IDLitWindow::AddWindowEventObserver](#) for details.

Syntax

Obj->[IDLitWindow::]OnMouseUp, X, Y, ButtonMask

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

ButtonMask

An integer containing a bitwise mask indicating which of the left, center, or right mouse button was released:

Bitmask	Mouse Button
1	Left
2	Middle
4	Right

Table 32-19: Bitmask for Button Events

Keywords

None

Implementing the OnMouseUp Interface

When defining a window event observer that handles mouse up events, you must implement an `OnMouseUp` procedure method with the following signature:

```
PRO OnMouseUp, Window, X, Y, ButtonMask
```

where the *Window* argument is an object reference to the `IDLitWindow` object in which the event was generated, and all of the other arguments are described above.

In addition, you must implement `OnKeyboard`, `OnMouseMotion`, and `OnMouseMotion` procedure methods, as discussed in “[IDLitWindow::AddWindowEventObserver](#)” on page 5122.

Version History

6.0	Introduced
-----	------------

[IDLitWindow::AddWindowEventObserver](#), [IDLitWindow::OnKeyboard](#), [IDLitWindow::OnMouseDown](#), [IDLitWindow::OnMouseMotion](#)

IDLitWindow::OnResize

The IDLitWindow::OnResize procedure method handles notification from the window that a resize event has occurred.

Note

By default, the OnResize method will automatically resize the window and then call the OnResize method for the contained scene. If you are using a subclass of IDLitWindow and require additional functionality, you should override this method. Your method will be automatically called when a resize event occurs.

Syntax

Obj->[IDLitWindow::]OnResize, *Width*, *Height*

Arguments

Width

A floating-point value representing the new width of the canvas (in device coordinates).

Height

A floating-point value representing the new height of the canvas (in device coordinates).

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitWindow::OnScroll

The `IDLitWindow::OnScroll` procedure method handles notification (from the native window device) that a scrolling event has occurred. This notification is passed on to the window's scene, which handles the cropping of each of its contained views. A scene represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window.

Syntax

Obj->`[IDLitWindow::]OnScroll, X, Y`

Arguments

X

A long integer representing the *x*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

Y

A long integer representing the *y*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow::OnTimer

The IDLitWindow::OnTimer procedure method handles notification (from the native window device) that a timer event has occurred, and passes that notification to all observers in the list of window event observers (as specified by calls to the [IDLitWindow::AddWindowEventObserver](#) method). You can also *simulate* a timer event by calling this method directly.

Note

Window event observers that handle timer events *must* implement the OnTimer method, as described in “[Implementing the OnTimer Interface](#)” on page 5152. See [IDLitWindow::AddWindowEventObserver](#) for details.

Note

See “[Designing a Behavior Object](#)” (Chapter 10, *Object Programming*) for examples that implement the OnTimer method in an animation display.

Syntax

Obj->[IDLitWindow::]OnTimer

Arguments

None

Keywords

None

Implementing the OnTimer Interface

When defining a window event observer that handles timer events, you must implement an OnTimer procedure method with the following signature:

```
PRO OnTimer, Window
```

where the *Window* argument is an object reference to the IDLitWindow object in which the event was generated.

Version History

6.2	Introduced
-----	------------

See Also

[IDLitWindow::AddWindowEventObserver](#)

IDLitWindow::OnWheel

The IDLitWindow::OnWheel procedure method handles notification (from the native window device) that a mouse wheel event has occurred, and passes along that notification to all observers in the list of window event observers (as specified by calls to the [IDLitWindow::AddWindowEventObserver](#) method). You can also simulate a mouse wheel event by calling this method directly.

Note

Window event observers that handle mouse wheel events must implement the OnWheel method, as described in “[Implementing the OnWheel Interface](#)” on page 5155.

Syntax

Obj->[IDLitWindow::]OnWheel, *X*, *Y*, *Delta*, *Modifiers*

Arguments

X

A long integer representing the *x*-location (in device coordinates) of the mouse event.

Y

A long integer representing the *y*-location (in device coordinates) of the mouse event.

Delta

A long integer giving the direction and distance that the wheel was rolled. Pushing the wheel generates positive values, pulling the wheel generates negative values. The magnitude of the value depends on the device setting for the individual mouse, but is usually limited to small integer values such as +1, -1, +2, -2, etc.

Modifiers

A long integer containing a bitwise mask indicating which modifier keys are active at the time of the wheel event. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bit mask:

Bit	Value	Modifier Key
0	1	Shift
1	2	Control
2	4	Caps Lock
3	8	Alt

Table 32-20: Modifier Values

Keywords

None

Implementing the OnWheel Interface

When defining a window event observer that handles mouse wheel events, you must implement an `OnWheel` procedure method with the following signature:

```
PRO MyObject::OnWheel, Window, X, Y, Delta, Modifiers
```

where the *Window* argument is an object reference to the `IDLitWindow` object in which the event was generated, and all of the other arguments are described above.

Version History

6.4	Introduced
-----	------------

See Also

[IDLitWindow::AddWindowEventObserver](#)

IDLitWindow::Remove

The IDLitWindow::Remove procedure method removes the given object(s) from the window.

Syntax

Obj->[IDLitWindow::]Remove, *Object* [, /ALL] [, POSITION=index]

Arguments

Object

A reference (or vector of references) to the object(s) to be removed from this window.

Keywords

ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Object* argument is supplied, this keyword is ignored.

Version History

6.0	Introduced
-----	------------

IDLitWindow::RemoveWindowEventObserver

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

Syntax

Obj->[IDLitWindow::]RemoveWindowEventObserver, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow::Resize

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

Syntax

Obj->[IDLitWindow::]Resize, *Objects*

Arguments

Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLitWindow::SetCurrentZoom

The IDLitWindow::SetCurrentZoom procedure method sets the current zoom factor for this window by changing its virtual dimensions. Setting the zoom factor on this window overrides any zoom factor inherited from the IDLgrWindow. The contents of the window are updated to reflect the new zoom factor.

Syntax

Obj->[IDLitWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

Arguments

ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 result in a zooming out; values greater than 1.0 result in a zooming in on the contents of the window.

Keywords

RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

Version History

6.0	Introduced
-----	------------

IDLitWindow::SetEventMask

The IDLitWindow::SetEventMask procedure method enables the given events within this window.

When an event occurs within this window, if the corresponding event type is enabled, then the list of its window event observers will be notified of the event. See “IDLitWindow::AddWindowEventObserver” on page 5122 for more details.

Syntax

```
Obj->[IDLitWindow::]SetEventMask, [EventMask] [, /BUTTON_EVENTS]
    [, /KEYBOARD_EVENTS] [, /MOTION_EVENTS] [, /TIMER_EVENTS]
    [, /TRACKING_EVENTS] [, /WHEEL_EVENTS]
```

Arguments

EventMask

An unsigned long integer representing the bitwise mask for the events that are to be enabled for this window. The bits in the mask are as follows:

Bit	Value	Event
0	1	Button Events
1	2	Motion Events
2	4	Keyboard Events
3	8	Tracking Events
4	16	Timer Events
5	32	Wheel Events

Table 32-21: Bits of the Event Mask

This argument is optional; the keywords described below may be used instead.

Keywords

BUTTON_EVENTS

Set this keyword to indicate that mouse button events are to be enabled for this window.

KEYBOARD_EVENTS

Set this keyword to indicate the keyboard events are to be enabled for this window.

MOTION_EVENTS

Set this keyword to indicate that mouse motion events are to be enabled for this window.

TIMER_EVENTS

Set this keyword to indicate that timer events are to be enabled for this window.

TRACKING_EVENTS

Set this keyword to indicate that tracking events are to be enabled for this window.

Warning

In order to receive tracking events, you *must* implement the [IDLitWindow::OnEnter](#) and [IDLitWindow::OnExit](#) methods in your own subclass of the IDLitWindow class.

WHEEL_EVENTS

Set this keyword to indicate that mouse wheel events are to be enabled for this window.

Version History

6.0	Introduced
6.2	Added <code>TIMER_EVENTS</code> keyword
6.4	Added <code>WHEEL_EVENTS</code> keyword

IDLitWindow::SetManipulatorManager

The IDLitWindow::SetManipulatorManager procedure method sets the given IDLitManipulatorManager object as the current manager of this window's manipulators.

Syntax

Obj->[IDLitWindow::]SetManipulatorManager, *Manager*

Arguments

Manager

A reference to the IDLitManipulatorManager object that is to serve as the manager for this window's manipulators.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow:: SetProperty

The IDLitWindow::SetProperty procedure method sets the value of an IDLitWindow property, and should be called by the subclass's SetProperty method. This method also calls the superclass's SetProperty method.

Syntax

Obj->[IDLitWindow::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “IDLitWindow Properties” on page 5120 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitWindow::SetTimerInterval

The `IDLitWindow::SetTimerInterval` procedure method specifies the floating-point number of seconds between timer events. When a timer event occurs, the window calls the `OnTimer` method of all window event observers. The generation of timer events is controlled by the window event mask.

See “[Controlling the Animation Rate](#)” (Chapter 10, *Object Programming*) for examples of using this method in an animation display.

Syntax

Obj->[IDLitWindow::]SetTimerInterval, *Interval*

Arguments

Interval

The default interval value is 0, which indicates that the timer event interval is the smallest amount of time allowed by the system.

Keywords

None

Version History

6.2	Introduced
-----	------------

IDLitWindow::ZoomIn

The IDLitWindow::ZoomIn procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the inherited IDLgrWindow `ZOOM_BASE` property). The contents of the window are updated to reflect the new zoom factor. See “IDLitWindow::SetCurrentZoom” on page 5159 for additional details.

Syntax

Obj->[IDLitWindow::]ZoomIn

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWindow::ZoomOut

The IDLitWindow::ZoomOut procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the inherited IDLgrWindow `ZOOM_BASE` property). The current contents of the window are updated to reflect the new zoom factor. See “IDLitWindow::SetCurrentZoom” on page 5159 for additional details.

Syntax

Obj->[IDLitWindow::]ZoomOut

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWriter

The IDLitWriter class defines the interface used to construct file writers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file writer class.

This class is written in the IDL language. Its source code can be found in the file `idlitwriter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

Superclasses

[IDLitComponent](#)

[IDLitMessaging](#)

Note

See the “[iTools Object Model Diagram](#)” (Chapter 2, *iTool Developer’s Guide*) for a visual representation of the iTools object model hierarchy.

Creation

See “[IDLitWriter::Init](#)” on page 5174.

Properties

Objects of this class have the following properties. See “[IDLitWriter Properties](#)” on page 5169 for details on individual properties.

- [TYPES](#)

Methods

This class has the following methods:

- [IDLitWriter::Cleanup](#)
- [IDLitWriter::GetFileExtensions](#)
- [IDLitWriter::GetFilename](#)
- [IDLitWriter::GetProperty](#)
- [IDLitWriter::Init](#)

- [IDLitWriter::IsA](#)
- [IDLitWriter::SetData](#)
- [IDLitWriter::SetFilename](#)
- [IDLitWriter::SetProperty](#)

In addition, this class inherits the methods of its superclasses.

Examples

See [Chapter 10, “Creating a File Writer”](#) (*iTool Developer’s Guide*) for examples using this class and its methods.

Version History

6.0	Introduced
-----	------------

IDLitWriter Properties

IDLitWriter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via [IDLitWriter::GetProperty](#). Properties with the word “Yes” in the “Init” column of the properties table can be initialized via [IDLitWriter::Init](#). Properties with the word “Yes” in the “Set” column of the properties table can be set via [IDLitWriter::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [TYPES](#)

In addition, objects of this class inherit:

- [IDLitComponent](#)
- [IDLitIMessaging](#)

TYPES

Set this property to a string or an array of strings indicating the types of data that this file writer accepts. iTools data types are described in [Chapter 3, “Data Management”](#) (*iTool Developer’s Guide*). Set this property to a null string (' ') to specify that the file reader can accept all types of data.

Property Type	User Defined		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

IDLitWriter::Cleanup

The IDLitWriter::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLitWriter::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWriter::GetFileExtensions

The IDLitWriter::GetFileExtensions method is called by the system to retrieve the file extensions supported by this particular writer.

Syntax

```
Result = Obj->[IDLitWriter::]GetFileExtensions( [, COUNT=count])
```

Return Value

Returns a scalar or string array that contains the file extensions associated with this writer.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of file extensions returned by this method.

Version History

6.0	Introduced
-----	------------

IDLitWriter::GetFilename

The IDLitWriter::GetFilename function method is called by the system to retrieve the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time. This method allows direct access to the file currently associated with the writer.

In addition, this methodology is helpful when multiple writes are performed from a given file.

Syntax

Result = *Obj*->[IDLitWriter:]GetFilename()

Return Value

Returns a string containing the current file name associated with this writer, or an empty string if no filename has been associated.

Arguments

None

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWriter::GetProperty

The IDLitWriter::GetProperty procedure method retrieves the value of an IDLitWriter property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

Syntax

Obj->[IDLitWriter::]GetProperty[, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 5169 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.0	Introduced
-----	------------

IDLitWriter::Init

The IDLitWriter::Init function method initializes the IDLitWriter object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLitWriter' [, Extensions] [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLitWriter::]Init( [, Extensions] [, PROPERTY=value] ) (In a  
lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

Arguments

Extensions

A optional argument containing a scalar or string array with the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (i.e., a correct value is 'jpeg' and not '.jpeg'). If this argument is not set, or if a null string is provided, IDL does not include this file writer in the list of filters in a file-selection dialog, but still uses it when attempting to match a file to a writer.

Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 5169 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.0	Introduced
-----	------------

IDLitWriter::IsA

The IDLitWriter::IsA function method is called by the system to determine if the given file is of the type supported by this file writer. Often this is used to determine what file writer to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new writer is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

Syntax

```
Result = Obj->[IDLitWriter::]IsA(Filename)
```

Return Value

Returns a 1 if the writer supports this type of file, or a 0 if the writer does not support this type of file.

Arguments

Filename

A string scalar representing of the filename, which is used to check and determine if the writer supports its format.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWriter::SetData

The IDLitWriter::SetData function method is called by the system to set the data for the current file. When called, the writer should access the current filename and write the desired data.

This method will contain a majority of the implementation for a new writer class.

Syntax

Result = Obj->[IDLitWriter::]SetData(*Data*)

Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

Arguments

Data

A data object that contains the information to be written.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWriter::SetFilename

The IDLitWriter::SetFilename procedure method is called by the system to set the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time.

Syntax

Obj->[IDLitWriter::]SetFilename, *Filename*

Arguments

Filename

A string that contains the filename associated with this writer.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLitWriter:: SetProperty

The IDLitWriter::SetProperty procedure method sets the value of an IDLitWriter property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

Syntax

Obj->[IDLitWriter::]SetProperty[, *PROPERTY*=*value*]

Arguments

None

Keywords

Any property listed under “[IDLitWriter Properties](#)” on page 5169 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Chapter 33

Network Object Classes

This chapter describes IDL's built-in network object class library.

About Network Objects	5182	IDLnetOGCWMS	5262
IDLnetOGCWCS	5183	IDLnetURL	5335

About Network Objects

IDL provides object classes that facilitate communication and file transfer between IDL and several different types of network-based resources.

Generic Network Resources

The [IDLnetURL](#) object class provides a mechanism whereby IDL programs can transfer information to and from network servers using the HTTP and FTP protocols. Any data that can be transferred using a web browser or FTP client application can be transferred using the URL object.

Geospatial Network Resources

The Open Geospatial Consortium (OGC) is an open-standards organization devoted to developing standards that govern web-based delivery of geospatial data including geographical information systems (GIS) data combined with location, elevation or other types of structure data. Common OGC specifications include the following three client/server protocols:

- WMS (Web Map Service) — returns rendered image layers containing information such as roads, topography, or municipal boundaries. The image layers can be combined into a single display.
- WCS (Web Coverage Service) — returns unrendered data containing sensor data, hyperspectral data, elevation data, or imagery.
- WFS (Web Feature Service) — returns vectors of GML (Geography Markup Language) data describing elements such as roads, rivers, and property boundaries. This protocol supports creating, deleting, querying and updating vector information on the server.

IDL currently offers support for:

- WCS via the [IDLnetOGCWCS](#) object class
- WMS via the [IDLnetOGCWMS](#) object class

Using these objects, you can access and query servers that support the related OGC protocol (WCS or WMS). See “[Making OGC WCS Server Requests](#)” on page 5188 and “[Making OGC WMS Server Requests](#)” on page 5266 for more information.

The Open Geospatial Consortium web site (www.opengeospatial.org) provides full protocol specification details. See the web site to download specific service specifications and XML schema definition documents.

IDLnetOGCWCS

An IDLnetOGCWCS object lets you access a Web Coverage Service (WCS) server that supports the Open Geospatial Consortium (OGC) standards. The OGC is an international group working to develop standards for the exchange of geospatial content and services including specifications for web delivery of data that combines location and geospatial information.

For additional information on IDL's WCS features, see the following sections:

- [“Web Coverage Service \(WCS\) Overview”](#) on page 5186
- [“Supported OGC WCS Version”](#) on page 5187
- [“Translating a URL into Property Values”](#) on page 5189
- [“Using Callbacks with the IDLnetOGCWCS Object”](#) on page 5191
- [“HTTP Authentication, Security and Encoding”](#) on page 5193

Note

See [“Feature Support by Operating System”](#) (Chapter 2, *What's New in IDL 7.1*) for information on which IDL platforms support the IDLnetOGCWCS object.

Note

A sample IDL program included in the IDL distribution provides a generic WCS browser that lets you peruse and request coverages from a remote OGC server. See [“Sample WCS Browser”](#) on page 5185 for details.

Superclasses

None

Creation

See [“IDLnetOGCWCS::Init”](#) on page 5256.

Properties

Objects of this class have the following properties. See “IDLnetOGCWCS Properties” on page 5195 for details on individual properties.

• AUTHENTICATION	• CALLBACK_DATA
• CALLBACK_FUNCTION	• CAPABILITIES_FILENAME
• CONNECT_TIMEOUT	• CONTENT_TYPE
• COVERAGE_FILENAME	• DESCRIBE_COVERAGE_FILENAME
• ENCODE	• HEADERS
• LAST_FILE	• PASSWORD
• PROXY_AUTHENTICATION	• PROXY_HOSTNAME
• PROXY_PASSWORD	• PROXY_PORT
• PROXY_USERNAME	• RESPONSE_HEADER
• SSL_CERTIFICATE_FILE	• SSL_VERIFY_HOST
• SSL_VERIFY_PEER	• TIMEOUT
• URL_HOSTNAME	• URL_PATH
• URL_PORT	• URL_QUERY_PREFIX
• URL_QUERY_SUFFIX	• URL_SCHEME
• USERNAME	• VERBOSE
• WCS_VERSION	

Methods

This class has the following methods:

- IDLnetOGCWCS::Cleanup
- IDLnetOGCWCS::DescribeCoverage
- IDLnetOGCWCS::GetCapabilities
- IDLnetOGCWCS::GetCoverage

- [IDLnetOGCWCS::GetCoverageOffering](#)
- [IDLnetOGCWCS::GetCoverageOfferingBriefs](#)
- [IDLnetOGCWCS::GetProperty](#)
- [IDLnetOGCWCS::GetServiceSection](#)
- [IDLnetOGCWCS::Init](#)
- [IDLnetOGCWCS::ParseUrl](#)
- [IDLnetOGCWCS::SetProperty](#)

Examples

See the following methods for examples:

- [IDLnetOGCWCS::DescribeCoverage](#)
- [IDLnetOGCWCS::GetCapabilities](#)
- [IDLnetOGCWCS::GetCoverage](#)
- [IDLnetOGCWCS::GetCoverageOfferingBriefs](#)
- [IDLnetOGCWCS::ParseUrl](#)

Sample WCS Browser

The IDL distribution includes a sample program that allows you to enter a working URL to an OGC server and then call `GetCapabilities`, `DescribeCoverage` and `GetCoverage` from within the user interface. You can modify property values and query characteristics to return the desired data. To run the browser program, enter `OGC_WCS` at the command line. See the browser help for more information.

Tip

You can use the example IDL OGC WCS Browser as a template for creating an application that queries a remote WCS server. This example is located in the `IDL_DIR\examples\ogc\wcs` directory where `IDL_DIR` is the directory where you have installed IDL. Running the example lets you parse a known, working URL to an OGC WCS server, and then make `GetCapabilities`, `DescribeCoverage` and `GetCoverage` requests. By default, returned files are written to your application user directory, a subdirectory of your home directory.

Version History

-----	------------

Web Coverage Service (WCS) Overview

A request for coverage data from an OGC WCS server involves three main requests: GetCapabilities, DescribeCoverage, and GetCoverage. The following describes these operations in terms of the IDLnetOGCWCS object:

- **GetCapabilities** — a general query that returns information about what types of requests are allowed and available. This includes service and summary information about data collections that are contained in “coverage offering briefs,” which are transmitted in an XML file that is written to disk.
- **DescribeCoverage** — a request that asks for detailed information about one or more specific coverages where each coverage is a data collection. The server returns details about the coverage(s) in an XML file that is written to disk.
- **GetCoverage** — a request for data relating to a specific coverage. The server transmits a copy of the raw data, containing values or properties of a set of geographic locations, in a file that is written to disk.

For details on how to use the IDLnetOGCWCS object properties and methods to request and receive information from an OGC server, see [“Making OGC WCS Server Requests”](#) on page 5188. Also see [“Sample WCS Browser”](#) on page 5185 for information about the IDL OGC WCS Browser, a sample program included in the IDL distribution.

Additional OGC Web Coverage Service Resources

The Open Geospatial Consortium web site provides complete details on the Web Coverage Service protocol including the WCS specification and schema documents. You may find the following documents helpful if you need additional WCS resources.

See OGC web site (www.opengeospatial.org) to search for these and other resource files.

Document	Description
Specification	OGC Web Coverage Service, Version 1.0.0, Ref# OGC 05-076r6, 2005-10-14
Schema Definition Documents	
wcsCapabilities.xsd	XML schema definition used by the remote server when creating a GetCapabilities response, which contains one or more coverage offering briefs
describeCoverage.xsd	XML schema definition used by the remote server when creating a DescribeCoverage response, which contains one or more coverage offerings
owsBase.xsd	XML schema definition containing base types used in the wcsCapabilities.xsd and describeCoverage.xsd
values.xsd	XML schema definition containing base types used in the wcsCapabilities.xsd and describeCoverage.xsd
gml4wcs.xsd	XML schema definition containing GML types used in the wcsCapabilities.xsd, describeCoverage.xsd and owsBase.xsd

Table 33-1: OGC WCS Reference Documents

Supported OGC WCS Version

This object supports version 1.0.0 of the OGC WCS standard. The IDLnetOGCWCS object conforms to the OGC WCS standard and is designed to communicate with OGC WCS compliant servers.

Note

Since this object is designed as an OGC WCS client, OGC WCS certification is not applicable. Compliance testing and certification is valid only for WCS servers.

Making OGC WCS Server Requests

This section outlines the steps required to query and return information from an OGC server. The goal is to return a data file containing a specific geospatial coverage as unrendered data. A coverage is gridded data that typically has a 1-, 2-, or 3-axis spatial coordinate reference system. Broadly, an information request from a WCS sever requires determining what data is available from a server (coverage offering briefs), determining what data collection (coverage offerings) from which you want to request data (a coverage), making the requests, and returning unrendered data.

Note

You can implement a callback to return information about the status of requests. See [“Using Callbacks with the IDLnetOGCWCS Object”](#) on page 5191 for details.

After you create an IDLnetOGCWCS object, you will need to complete the following steps:

1. Identify the WCS server. The easiest way to do this is to pass a *working* URL to the [IDLnetOGCWCS::ParseUrl](#) method, which sets the required URL_HOSTNAME and URL_PATH properties. Alternately, you can manually set properties related to the URL. See [“Translating a URL into Property Values”](#) on page 5189 for information on which URL components belong to which IDLnetOGCWCS properties.

Note

If dealing with secure WCS servers, see [“HTTP Authentication, Security and Encoding”](#) on page 5193 for additional information.

2. Determine what information is available on the WCS server by making a GetCapabilities request. This typically returns and parses an XML file that contains brief information about the available coverages. See [IDLnetOGCWCS::GetCapabilities](#) for details. You can modify the [CAPABILITIES_FILENAME](#) property to define the location this file is stored.
3. Return the information contained in the coverage offering briefs by calling [IDLnetOGCWCS::GetCoverageOfferingBriefs](#). You must call this method to return information for the specified coverage offering brief(s) in an IDL structure. The NAME field value of this structure is required to request additional information from an OGC server using the DescribeCoverage method, described next. If you wish, you can also call [IDLnetOGCWCS::GetServiceSection](#) to return service information from the XML file, but this is not necessary.

4. Request detailed information about one or more coverage offerings by specifying a value for the NAME keyword in the `IDLnetOGCWCS::DescribeCoverage` call. The server will typically return an XML file containing detailed information about the coverage(s). You can modify the `DESCRIBE_COVERAGE_FILENAME` property to define the location this file is stored.
5. Access the information in the XML file returned by `DescribeCoverage` by calling `IDLnetOGCWCS::GetCoverageOffering`. This returns a complex structure describing the offering details.
6. Return data from the server by calling `IDLnetOGCWCS::GetCoverage` with a number of parameters describing the exact data to be returned. You can modify the `COVERAGE_FILENAME` property to define the location this file is stored.
7. Model and render the data as defined by your application.

Translating a URL into Property Values

A valid WCS server URL is required to establish communication with an OGC WCS server. Additionally, IDLnetOGCWCS URL-related property values must be set before data can be successfully requested from a OGC WCS server. Either set the required properties manually (using `SetProperty`) or pass a URL to `ParseURL`. The `IDLnetOGCWCS::ParseUrl` method automatically parses a given URL and sets related property values.

Note

Regardless of how properties are set, the `URL_HOSTNAME` and `URL_PATH` properties must be set before calling the `GetCapabilities`, `DescribeCoverage` or `GetCoverage` methods.

The following table describes how the components of a given URL should be assigned to property values. Consider the following URL (which would typically exist on a single line):

```
http://my.hostname.com:8080/demo/cgi_path?customprefix&
Version=1.0.0&SERVICE=WCS&CustomMiddle&Request=GetCapabilities&
CustomSuffix
```

Components of this URL map to properties as follows.

Property	Value
URL_SCHEME	http
URL_HOSTNAME	my.hostname.com
URL_PORT	8080
URL_PATH	demo/cgi_path
WCS_VERSION	Version=1.0.0
URL_QUERY_PREFIX	CustomPrefix&CustomMiddle
URL_QUERY_SUFFIX	CustomSuffix

Table 33-2: Mapping URL Components to Properties

The *query* portion of the URL passed to a WCS server (the *parameter=value* pairs following the ? character) always includes the following three parameters:

- *Version* takes its value from the WCS_VERSION property
- *Service* is set equal to “WCS” for the IDLnetOGCWCS object
- *Request* is one of “GetCapabilities”, “DescribeCoverage”, or “GetCoverage” depending on the method in use

These three parameters are inserted into the URL automatically by IDL; any values specified for these parameters in the URL are ignored. They are *not* included when the URL_QUERY_PREFIX or URL_QUERY_SUFFIX properties are returned by the GetProperty method. Any query parameters that precede *any* of the three required parameters will be included in the URL_QUERY_PREFIX property by the ParseURL method; other nonrequired parameters will be included in the URL_QUERY_SUFFIX property.

Note

If not specified in the URL, property values besides URL_HOSTNAME and URL_PATH are set to default values. For example, the URL_PORT property defaults to 80 and the WCS_VERSION defaults to 1.0.0.

Using Callbacks with the IDLnetOGCWCS Object

Callbacks from the IDLnetOGCWCS object provide a way to transmit information back to the caller based on the status of a request made to a remote OGC WCS server. The value returned by the callback function is then used by the IDLnetOGCWCS object to determine whether to continue or abort the request.

The IDLnetOGCWCS object lets you define a single function (written in IDL) that will be called during a GetCapabilities, DescribeCoverage, or GetCoverage method call. If a callback function is specified via the CALLBACK_FUNCTION property, it is called in the following circumstances:

- For the [IDLnetOGCWCS::GetCapabilities](#) method, the callback function is called each time a packet is received from the OGC WCS server. If the FROM_FILE keyword is set, the callback function is called before and after the XML file is parsed.
- For the [IDLnetOGCWCS::DescribeCoverage](#) method, the callback function is called each time a packet is received from the OGC WCS server. If the FROM_FILE keyword is set, the callback function is called before and after the XML file is parsed.
- For the [IDLnetOGCWCS::GetCoverage](#) method, the callback function is called each time a packet of data is received from the OGC WCS server.

All methods invoke the callback function with an array of strings indicating status as the first parameter, an array of integers containing progress information as the second parameter, and with the value (if any) specified by the CALLBACK_DATA property as the third parameter. A callback function returns a value of type Int.

Canceling a Request

The return value of the callback function should be an integer zero or one. If the return value is zero, a cancel message will be sent to the remote node. If the return value is one, the operation will continue.

Callback Routine Signature

A callback function is written in IDL and has the following signature:

```
Function Callback_Function_Name, StatusInfo, ProgressInfo,  
        CallbackData
```

where

- `Callback_Function_Name` is the name of the callback function. This value is specified as the value of the [CALLBACK_FUNCTION](#) property.

- `StatusInfo` is an array of strings that contain status information about the operation. The status strings are provided for information and human inspection rather than for programmatic processing; the exact strings included in the array will depend on numerous factors including the status of the operation and the type of OGC WCS server.
- `ProgressInfo` is an array of five 64-bit long integers that contain progress information for the transfer:
 - `ProgressInfo[0]` – Contains 1 (one) when the `ProgressInfo` array contains valid data, or 0 (zero) when the array does not contain valid data.
 - `ProgressInfo[1]` – Contains the total number of bytes to be downloaded. This array element will contain 0 (zero) when the transfer encoding is “chunked.”
 - `ProgressInfo[2]` – Contains the number of bytes that have been downloaded during the current transfer.
 - `ProgressInfo[3]` – Contains the total number of bytes to be uploaded.
 - `ProgressInfo[4]` – Contains the number of bytes that have been uploaded during the current transfer.
- `CallbackData` is the data specified via the `CALLBACK_DATA` property. The value of this property is passed to the callback function unmodified. If the `CALLBACK_DATA` property is unspecified, an integer zero is passed to the callback function as the value of this parameter.

The `CallbackData` parameter is useful for passing static information, such as the widget ID of a widget where the status information is displayed, from the `IDLnetOGCWCS` object to the callback routine.

For a simple example of using a callback to return additional status information, see “[IDLnetOGCWCS::GetCapabilities](#)” on page 5218. The `StatusInfo` details are printed to the Output window.

HTTP Authentication, Security and Encoding

The following sections describe the IDLnetOGCWCS object's support of HTTP protocols including:

- [“HTTP Authentication”](#)
- [“HTTP Security”](#)
- [“HTTP Encoding”](#)

HTTP Authentication

The IDLnetOGCWCS object supports the following HTTP authentication modes for WCS and proxy servers:

- Disabled—no authentication
- Basic—plain text transmission of username and password
- Digest—encrypted transmission of username and password

By default, [AUTHENTICATION](#) and [PROXY_AUTHENTICATION](#) properties are set to “Basic and Digest” option, meaning that either basic or digest authentication are supported. However, for this setting to be honored, the corresponding username and password properties must also be set:

- For authentication on an OGC server, set [USERNAME](#) and [PASSWORD](#) properties
- For authentication on a proxy server, set [PROXY_USERNAME](#) and [PROXY_PASSWORD](#) properties

HTTP Security

The IDLnetOGCWCS object also supports HTTPS through the implementation of Secure Socket Layer (SSL). With SSL encryption, all requests and responses are encrypted. When the [URL_SCHEME](#) property is set to “https”, use the [SSL_CERTIFICATE_FILE](#), [SSL_VERIFY_HOST](#), and [SSL_VERIFY_PEER](#) properties to define security-related parameters.

Note

If you receive a PRNG (Pseudo Random Number Generator) error when attempting to use HTTPS on UNIX, you need to install either `dev/random` or `dev/urandom` in order to generate secure keys.

HTTP Encoding

The IDLnetOGCWCS object supports compressed and encoded responses from a remote OGC WCS server. Supported encoding formats are:

- DEFLATE
- GZIP

See the [ENCODE](#) property for details.

IDLnetOGCWCS Properties

IDLnetOGCWCS objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via `IDLnetOGCWCS::Init`.

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties.

- AUTHENTICATION
- CALLBACK_DATA
- CALLBACK_FUNCTION
- CAPABILITIES_FILENAME
- CONNECT_TIMEOUT
- CONTENT_TYPE
- COVERAGE_FILENAME
- DESCRIBE_COVERAGE_FILENAME
- ENCODE
- HEADERS
- LAST_FILE
- PASSWORD
- PROXY_AUTHENTICATION
- PROXY_HOSTNAME
- PROXY_PASSWORD
- PROXY_PORT
- PROXY_USERNAME
- RESPONSE_HEADER
- SSL_CERTIFICATE_FILE
- SSL_VERIFY_HOST
- SSL_VERIFY_PEER
- TIMEOUT
- URL_HOSTNAME
- URL_PATH
- URL_PORT
- URL_QUERY_PREFIX
- URL_QUERY_SUFFIX
- URL_SCHEME
- USERNAME
- VERBOSE
- WCS_VERSION

AUTHENTICATION

This property specifies the type of authentication used when connecting to an OGC server. Supported authentication modes are:

0	Disabled — authentication is disabled.
1	Basic only — username and password are sent as plain text.

2	Digest only — username and password are encrypted before being sent.
3	Basic and digest — either basic or digest is used depending on the mode preferred by the remote server. This is the default.

When AUTHENTICATION is set, one or both of the [USERNAME](#) and [PASSWORD](#) properties must also be set. If neither of these properties is set, this property is ignored.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CALLBACK_DATA

This property contains data that is to be passed to the function defined by the [CALLBACK_FUNCTION](#) property when a callback is initiated. The data contained in the variable is defined and set by the caller. When a callback is initiated, this data is passed, unmodified, directly to callback function. Data can be of any type supported by IDL variables including numerical, string, pointer and structure data. If this property is not set, the GetCapabilities, DescribeCoverage, and GetCoverage methods will pass the integer value zero to the callback function.

Property Type	Any IDL variable		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CALLBACK_FUNCTION

This property is the name of the .pro code function to be called when GetCapabilities, DescribeCoverage, and GetCoverage, methods are retrieving information from the remote server. The function provides status information in addition to providing a way to cancel an operation. If this property is not set, then no callbacks will be made by the previously noted methods. See “[Using Callbacks with the IDLnetOGCWCS Object](#)” on page 5191 for more information.

The default value is a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CAPABILITIES_FILENAME

The [IDLnetOGCWCS::GetCapabilities](#) method returns and stores an XML file that contains the coverage offering briefs available on the remote server. Set this property to define the path and filename of this file, minus the extension. The file type extension is automatically set based on the type of file downloaded (typically .xml). If this property stays the same between calls to [GetCapabilities](#), the last file received is overwritten.

This property defaults to a file named `cap`, located in your application user directory. If a file was returned by the most recent call to the [GetCapabilities](#) method, the [LAST_FILE](#) property will contain the full path and filename of the downloaded file.

Note

Do not include a file type extension in the filename. If the retrieved file does not have the same extension as that given, the name will be appended with the file type extension of the received file (but this property will remain unchanged). For example, if you include the .xml extension (`cap.xml`) and the file received is an HTML file, the filename of the file on disk will be `cap.xml.html`, while this property remains `cap.xml`. Always omit the file type extension to avoid such inconsistencies.

This property cannot be set to a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONNECT_TIMEOUT

This property controls how long to wait for a successful connection to an OGC server before ending the attempt to establish a connection. The default is 180 seconds.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONTENT_TYPE

Set this read-only property to a variable that will indicate the document type of the last file received as a result of an HTTP GET request. The property is extracted from the contents of the Content-Type field found in an HTTP response header.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

COVERAGE_FILENAME

The [IDLnetOGCWCS::GetCoverage](#) method returns and stores a data file from the WCS server. Set this property to define the path and filename of this file, minus the extension. The file type extension is automatically set based on the type of file downloaded. If this property stays the same (the path and filename are unchanged, and the same type of file is retrieved) between calls to [GetCoverage](#), the last file received is overwritten.

This property defaults to a file named `cov`, located in your application user directory. If a file was returned by the most recent call to the [GetCoverage](#) method, the [LAST_FILE](#) property will contain the full path and filename of the downloaded file.

Note

Do not include a file type extension in the filename. If the retrieved file does not have the same extension as that given, the name will be appended with the file type extension of the received file (but this property will remain unchanged). For example, if you include the `.tiff` extension (`cov.tiff`) and the file received is an `.gm1` file, the filename of the file on disk will be `cov.tiff.gm1`, while this

property remains `cov.tiff`. Always omit the file type extension to avoid such inconsistencies.

This property cannot be set to a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

DESCRIBE_COVERAGE_FILENAME

The [IDLnetOGCWCS::DescribeCoverage](#) method returns and stores an XML file that contains the coverage offerings available on the remote server. Set this property to define the path and filename of this file, minus the extension. The file type extension is automatically set based on the type of file downloaded (typically `.xml`). If this property stays the same between calls to `DescribeCoverage`, the last file received is overwritten.

This property defaults to a file named `descov`, located in your application user directory. If a file was returned by the most recent call to the `DescribeCoverage` method, the [LAST_FILE](#) property will contain the full path and filename of the downloaded file.

Note

Do not include a file type extension in the filename. If the retrieved file does not have the same extension as that given, the name will be appended with the file type extension of the received file (but this property will remain unchanged). For example, if you include the `.xml` extension (`descov.xml`) and the file received is an HTML file, the filename of the file on disk will be `descov.xml.html`, while this property remains `descov.xml`. Always omit the file type extension to avoid such inconsistencies.

This property cannot be set to a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

ENCODE

This property determines if a compressed or encoded response will be requested from a remote OGC WCS server (during `GetCapabilities`, `DescribeCoverage`, and `GetCoverage` method calls). By default, the `IDLnetOGCWCS` object requests an unencoded response (`ENCODE=0`) in order to reduce the number of bytes that need to be sent over the network.

Note

The server does not have to respond with compressed or encoded data. You can determine the encoding, if any, by examining the “Content-Encoding” header in the response. See the [VERBOSE](#) property for information on how to access such information.

Allowable values are:

Value	Description
0	No encoding — do not request an encoded response. If the server sends a compressed or encoded response even though this was not requested, the response will not be decompressed or decoded and the output file will be written with the compressed or encoded data. This is the default
1	DEFLATE encoding — request and accept DEFLATE encoding. If the server replies with an encoded response, the data is decompressed or decoded before being written to the output file.
2	GZIP encoding — request and accept GZIP encoding. If the server replies with an encoded response, the data is decompressed or decoded before being written to the output file.
3	DEFLATE and GZIP encoding — request and accept both types of encoded responses. If the server replies with an encoded response, the data is decompressed or decoded before being written to the output file.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HEADERS

Note

This property is set automatically and need not be modified unless you have specific HTTP header information that you want included in a GET request sent to a remote WCS server.

Warning

This property is automatically set to the default value (clearing any custom header information) after a call to any IDLnetOGCWCS::Get* method except GetProperty. Clearing the HEADERS property prevents the inadvertent use of custom header values in future calls to Get methods.

Set this property to a string or array of strings containing one or more valid header fields and values separated by a colon. Each string in the string array should contain a single header field.

The HTTP header Host, Accept, and Encode fields are set by default. To add, disable or modify headers, do one of the following:

- Add a custom header by setting this property equal to a string containing a valid header field and value or a string array containing multiple strings. This property can be called multiple times to append additional header fields to the list of existing custom header items.
- Disable an existing header by setting the HTTP header field name equal to no value (no data on the right side of the colon). For example, HEADERS="Accept:" disables the header field.
- Add a header without contents by setting a header field equal to an empty string. For example, HEADERS="Accept: ' '" clears the field contents.

Set this property to an empty string to clear all custom headers and reset default values if appropriate. For example, HEADERS=' ' clears all custom changes.

Note

This method cannot be used to modify the first method line of a HTTP request (typically GET or POST).

Retrieving this property will return only those headers set using the Init or SetProperty methods. Use the **VERBOSE** keyword to see the default header information included in a request.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LAST_FILE

This property contains the full path and filename of the file retrieved from the last successful call to one of the GetCapabilities, GetCoverage, or DescribeCoverage methods. If the most recent call did not return a file, this property will contain a null string. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

PASSWORD

This property contains the password required for successful authentication with a secure WCS server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

PROXY_AUTHENTICATION

This property specifies the type of authentication that will be used when connecting to a proxy server. Supported authentication modes are:

0	Disabled — proxy authentication is disabled.
1	Basic only — proxy username and password are sent as plain text.
2	Digest only — proxy username and password are encrypted before being sent.
3	Basic and digest — either basic or digest is used depending on the mode preferred by the server. This is the default.

When PROXY_AUTHENTICATION is set and you are using a proxy server, the [PROXY_USERNAME](#) and [PROXY_PASSWORD](#) properties must also be set. If either of these properties are not set, then this property is ignored.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_HOSTNAME

This property specifies the hostname or IP address of the proxy server. This property must be set when connecting to an intranet or the internet through a proxy server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_PASSWORD

This property contains the password required for successful authentication with a secure proxy server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

PROXY_PORT

This property specifies the TCP/IP port that the proxy server listens to for incoming requests. The default value is “80”, the standard port for an HTTP request. This property must be set when connecting to an intranet or the internet through a proxy server.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_USERNAME

This property contains the username required for successful authentication with a secure proxy server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

RESPONSE_HEADER

This read-only property contains the HTTP response header from the last request made to an OGC WCS server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SSL_CERTIFICATE_FILE

Set this property to the full path and filename of the file containing one or more certificates to be verified with the peer when communicating with a secure server. The default location is `IDL_DIR/bin/bin.platform` directory where `IDL_DIR` is your IDL installation directory. A default bundle of Certificate Authority (CA) certificates is installed in this location. Use this property to specify the location of an alternate certificate file.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERIFY_HOST

When negotiating a SSL connection, the server sends a certificate indicating its identity. Use this property to determine whether you have connected to the expected server as follows:

0	No verification. The connection succeeds regardless of the name fields in the certificate.
1	Verify server. When this property is non-zero, the Common Name field or a Subject Alternate Name field in the certificate must match the host name in the URL (the URL_HOSTNAME property), or the connection fails. The default.

Note

To guard against a dishonest server, authenticate its certificate. See [“SSL_VERIFY_PEER”](#) on page 5206.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERIFY_PEER

SSL peer authentication depends on verification of a chain of digital signatures contained in one or more Certificate Authority (CA) certificates. See [“SSL_CERTIFICATE_FILE”](#) on page 5205 for information on the default CA certificates installed with IDL and how to supply your own certificates.

0	No verification. The connection succeeds regardless of the certificate’s authenticity.
1	Verify server. Set this property to a non-zero value to authenticate a certificate returned by a secure server. If certificate verification fails, the connection fails. The default.

Note

Certificate authentication is typically used in conjunction with server verification. See [“SSL_VERIFY_HOST”](#) on page 5205 for details.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TIMEOUT

This property controls how long to wait for the transmission from the OGC server to complete before ending the attempt. The default is 1800 seconds.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_HOSTNAME

This property specifies the host name or IP address of the remote OGC WCS server.

Note

This property and the [URL_PATH](#) property must be set before calling `GetCapabilities`, `DescribeCoverage`, or `GetCoverage`. The hostname and path elements are integral components of the request that is sent to the WCS server.

You can either set this property manually or pass a URL to the [IDLnetOGCWCS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)” on page 5189 for more information. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_PATH

This property specifies the path to the remote OGC WCS server.

Note

This property and the [URL_HOSTNAME](#) property must be set before calling `GetCapabilities`, `DescribeCoverage`, or `GetCoverage`. The path and hostname elements are integral components of the request that is sent to the WCS server.

You can either set this property manually or pass a URL to the [IDLnetOGCWCS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)” on page 5189 for more information. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_PORT

This property specifies the TCP/IP port at which the remote server listens for incoming requests. You can either set this property manually or pass a URL to the [IDLnetOGCWCS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)”

on page 5189 for more information. The default value is “80”, the standard port for an HTTP request.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_QUERY_PREFIX

This property specifies a prefix containing additional query information that will be prepended to the main portion of a request. You can either set this property manually or pass a URL to the `IDLnetOGCWCS::ParseUrl` method. See “[Translating a URL into Property Values](#)” on page 5189 for more information. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_QUERY_SUFFIX

This property specifies a suffix containing additional query information that will be appended to the main portion of a request. See “[Translating a URL into Property Values](#)” on page 5189 for more information on this property. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_SCHEME

This property specifies the name of the protocol used to communicate with the remote WCS server when a request is made. You can either set this property manually

or pass a URL to the [IDLnetOGCWCS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)” on page 5189 for more information. Possible values are:

String Value	Description
http	This is the default.
https	Use this setting when making a secure request and Secure Socket Layer (SSL) is supported by the remote WCS server. See SSL_CERTIFICATE_FILE , SSL_VERIFY_HOST , and SSL_VERIFY_PEER for SSL-related configuration parameters.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USERNAME

This property contains the username required for successful authentication with a secure WCS server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERBOSE

Set this property to return connection and HTTP header information associated with a [IDLnetOGCWCS::GetCapabilities](#), [IDLnetOGCWCS::DescribeCoverage](#), or [IDLnetOGCWCS::GetCoverage](#) method request.

0	Returns standard information (the default). Verbose is off.
Non-zero	Returns verbose information.

To access this information, the [CALLBACK_FUNCTION](#) property must also be set. The callback function’s *StatusInfo* variable will contain:

- INFO — messages about the TCP/IP connection to the remote server

- Header Out — messages about the HTTP header fields being sent to the remote server
- Header In — messages about the HTTP header fields received from the remote server

Each message is limited to 512 bytes of text. The default value is 0.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

For a simple example of using a callback to return VERBOSE status information, see “[IDLnetOGCWCS::GetCapabilities](#)” on page 5218.

WCS_VERSION

This property defines the version of the OGC WCS standard supported by the IDLnetOGCWCS object. The only valid value is “Version=1.0.0” for all requests.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLnetOGCWCS::Cleanup

The IDLnetOGCWCS::Cleanup method performs all cleanup on the object. All open network connections are closed when the IDLnetOGCWCS object is destroyed.

Note

Cleanup methods are special *lifecycle* methods, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLnetOGCWCS::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLnetOGCWCS::DescribeCoverage

The IDLnetOGCWCS::DescribeCoverage function method retrieves an XML file containing one or more descriptive coverage offerings from a remote OGC WCS server, writes the file to disk, and parses the file contents before returning. The XML file is written to disk according to the [DESCRIBE_COVERAGE_FILENAME](#) property, and will be overwritten if this property value remains unchanged between DescribeCoverage requests.

You can parse the contents of an existing XML file by setting the [FROM_FILE](#) keyword. This avoids having to download the same information as that which exists on disk.

Note

The [URL_PATH](#) and [URL_HOSTNAME](#) properties must be set before requesting information from a remote WCS server. You can either set these properties manually or pass a URL to the [IDLnetOGCWCS::ParseUrl](#) method prior to making a request. If you are dealing with a proxy server, you must also set the [PROXY_HOSTNAME](#) and [PROXY_PORT](#) properties to the correct values.

This method returns only when one of the following occur:

- Completes retrieval and parsing of information from server
- Encounters an HTTP error
- Encounters an OGC exception
- Responds to a cancel request as specified in a callback return value

To return status information during the request, set the [CALLBACK_FUNCTION](#) property. You can also use a callback to cancel a request. See “Using Callbacks with the IDLnetOGCWCS Object” on page 5191 for details. This method will throw an error if the DescribeCoverage request fails.

After this method returns, you must use [IDLnetOGCWCS::GetCoverageOffering](#) to return the coverage offerings details. The DescribeCoverage method accesses and parses the information retrieved from the server, and returns the names of the coverages, but does not return the detailed information.

Syntax

```
Result = Obj->[IDLnetOGCWCS::]DescribeCoverage ([, COUNT=variable]
[, FROM_FILE=value] , NAMES=value [, SCHEMA_CHECKING=value]
[, VALIDATION_MODE=value] )
```

Return Value

Returns a string array listing the names of the coverages returned by the remote WCS server. This is a subset of the information returned by the [IDLnetOGCWCS::GetCoverageOffering](#) method and can be useful when populating a user interface with the names of the available coverage offerings.

This method returns an empty string when no names are available.

Arguments

None

Keywords

COUNT

Set this keyword to a named variable that will contain the number of coverage offerings received.

FROM_FILE

Set this keyword to a string containing the full path and filename of the XML file to parse for coverage offering details. This allows you use a previously downloaded coverage offering file.

When you use the FROM_FILE keyword and the [CALLBACK_FUNCTION](#) property is set, status information will be returned when the XML file is first accessed and when parsing has ended. The entire file contents are parsed.

NAMES

Set this keyword to a string containing a single coverage name or a string array of coverage names for which to return detailed coverage offering information from the WCS server. The name of a coverage can be found by accessing the [NAME](#) field of the structure returned by the [IDLnetOGCWCS::GetCoverageOfferingBriefs](#) method.

Note

Not all servers accept a string array. Always check the number of coverages returned before proceeding to avoid unexpected errors.

Note

Setting the NAMES keyword is mandatory unless you are returning coverage information from a file using [FROM_FILE](#). Do not set both NAMES and FROM_FILE keywords.

When you use the NAMES keyword and the [CALLBACK_FUNCTION](#) property is set, status information will be returned each time a packet containing a portion of the file is delivered from the WCS server.

SCHEMA_CHECKING

XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, Document Type Definitions (DTDs). Schemas are typically provided via a link to an external document, which must be downloaded before validation can occur.

Set this keyword to one of the following values to control the degree of error-checking the parser should perform:

0	Turn schema checking off — the XML file is not checked for errors. Use this setting to avoid the delays associated with schema checking. This is the default.
1	Check for fatal schema errors in the XML file — this setting requires more time since the XML file is checked against a WCS schema reference document accessed from the OGC server.
2	Check for fatal errors in the XML file and schema document — this setting checks both the XML file and the reference schema document for fatal errors, and requires a considerable amount of time.

VALIDATION_MODE

XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. A DTD can be embedded in an XML document or provided via a link to an external document, which must be downloaded before validation can occur. In most applications, *schemas* provide a more robust validation mechanism.

Set this keyword to one of the following values to control DTD-based validation of the XML document:

0	Turn DTD validation off — external DTDs are not loaded and the XML file is not checked for errors. Use this setting to avoid the delays associated with loading and checking an external DTD. This is the default.
1	Validate only if an embedded DTD or a link to an external DTD is provided.
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Examples

The following example accesses an OGC server and requests two coverage offering briefs. Retrieve the names of the briefs from the `GetCoverageOfferingBriefs` structure and add them to a string array. Then use the `DescribeCoverage` method to return detailed information about those two coverages from the server. After getting detailed coverage information, use the `GetCoverageOffering` method to access this information as shown in “[Examples](#)” on page 5245.

Note

You may need to replace the URL in the following example as there is no guarantee that the given OGC server will be available when you attempt to establish the connection.

```
FUNCTION ogcwcs_callback, StatusInfo, CallbackData

PRINT, StatusInfo

; Indicate all is well.
vCancelFlag = 1
RETURN, vCancelFlag

END

PRO ogc_wcs_describecoverage_doc

; Use the DescribeCoverage method to return detailed information
; about a coverage, identified by name to the default descov.xml
; file. Access the coverage name by querying the
; GetCoverageOfferingBriefs method's structure.
```

```

; This example queries an OGC server at the following URL. Change
; the value of this variable to access a server of your choice.
url="http://data.itervis.com:80/cgi-bin" + $
    "/mapserv.exe?MAP=/OGC_Data/WCS/wcs_demo.map" + $
    "&SERVICE=WCS&VERSION=1.0.0&REQUEST=GetCapabilities"

; Catch error.
CATCH, errorStatus
IF (errorStatus NE 0) THEN BEGIN
    CATCH,/CANCEL
    r = DIALOG_MESSAGE(!ERROR_STATE.MSG, $
        TITLE='OGC WCS Error', /ERROR)
    PRINT, !ERROR_STATE.MSG
    IF OBJ_VALID(oWcs) THEN OBJ_DESTROY, oWcs
    RETURN
ENDIF

; Create an IDLnetOGCWCS object and parse a known, working URL to
; set mandatory properties.
oWcs = OBJ_NEW("IDLnetOGCWCS", $
    CALLBACK_FUNCTION="ogcwcs_callback")
oWcs->ParseUrl, url

; Return and parse a brief description of all data holdings
; on the WCS server.
count = oWCS->GetCapabilities()

; Initialize string array to hold names of briefs.
arrName=' '

; Make sure the server returned some coverage offering briefs.
IF (count NE 0) THEN BEGIN

    ; Return information about the holding using the
    ; GetCoverageOfferingBriefs method. The NAME field of the
    ; returned structure is used to identify what coverage
    ; to get more information about using the DescribeCoverage
    ; method. Here we return a maximum of 2 coverage briefs.
    ; You could use INDEX to specify the first item to return.
    briefStruct = oWCS->GetCoverageOfferingBriefs $
        (COUNT=briefcount, NUMBER=2)
    PRINT, "Returning structures for ", + briefcount, + " briefs"

    ; Access the name element of the GetCoverageOfferingBriefs
    ; structure.
    FOR x=0, briefCount-1 DO BEGIN
        PRINT, 'CoverageOfferingBrief = ', strtrim(x,2)
        PRINT, '    name          = ', briefStruct[x].name
        ; Add the name to the string array.

```

```

        arrName = [arrName, briefStruct[x].name]
    ENDFOR

    ; Strip out empty string element.
    arrName=arrName[1:*]
    PRINT, "Number of arrName elements = " $
        + STRING(N_ELEMENTS(arrName))

    ; Call DescribeCoverage to access coverage details for the
    ; coverages offerings in the array.
    covName = oWCS->DescribeCoverage(NAMES=arrName, COUNT=numCov)

    PRINT, "Number of coverages returned by DescribeCoverage = " $
        + STRING(numCov)
    PRINT, "Coverage Name(s) = " + covName

ENDIF ELSE BEGIN
    void = DIALOG_MESSAGE("No information available" $
        + "from WCS Server", /ERROR)
    RETURN
ENDELSE

; Cleanup.
OBJ_DESTROY, oWcs

END

```

[IDLnetOGCWCS::GetCoverageOffering](#)

IDLnetOGCWCS::GetCapabilities

The `IDLnetOGCWCS::GetCapabilities` function method retrieves an XML file containing coverage offering briefs from a remote OGC WCS server, writes the file to disk, and parses the file contents before returning. The XML file is written to disk according to the `CAPABILITIES_FILENAME` property, and will be overwritten if this property value remains unchanged between `GetCapabilities` requests.

You can parse the contents of an existing XML file by setting the `FROM_FILE` keyword. This avoids having to download the same information as that which exists on disk.

Note

The `URL_PATH` and `URL_HOSTNAME` properties must be set before requesting information from a remote WCS server. You can either set these properties manually or pass a URL to the `IDLnetOGCWCS::ParseUrl` method prior to making a request. If you are dealing with a proxy server, you must also set the `PROXY_HOSTNAME` and `PROXY_PORT` properties to the correct values.

This method returns only when one of the following occur:

- Completes retrieval and parsing of information from server
- Encounters an HTTP error
- Encounters an OGC exception
- Responds to a cancel request as specified in a callback return value

You can implement a callback to return status information during the request by setting the `CALLBACK_FUNCTION` property. You can also use a callback to cancel a request. See “Using Callbacks with the `IDLnetOGCWCS` Object” on page 5191 for details. This method will throw an error if the `GetCapabilities` request fails.

After this method returns, you must use `IDLnetOGCWCS::GetCoverageOfferingBriefs` to return information about the coverage offering briefs. The `GetCapabilities` method accesses and parses the information from the server and returns a count containing the number of briefs received, but does not provide immediate access to the detailed information. You can also use the `IDLnetOGCWCS::GetServiceSection` method to access information about services contained in the XML file.

Syntax

```
Result = Obj->[IDLnetOGCWCS::]GetCapabilities ([ ,FROM_FILE=string]
[,SCHEMA_CHECKING=value] [, VALIDATION_MODE=value])
```

Return Value

Returns the number of coverage offering briefs received.

Arguments

None

Keywords

FROM_FILE

Set this keyword to a string containing the full path and filename of the XML file to parse for coverage offering briefs and services. This allows you use a previously downloaded capabilities file.

When you use the FROM_FILE keyword and the [CALLBACK_FUNCTION](#) property is set, status information will be returned when the XML file is first accessed and when parsing has ended. The entire file contents are parsed.

SCHEMA_CHECKING

XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, Document Type Definitions (DTDs). Schemas are typically provided via a link to an external document, which must be downloaded before validation can occur.

Set this keyword to one of the following values to control the degree of error-checking the parser should perform:

0	Turn schema checking off — the XML file is not checked for errors. Use this setting to avoid the delays associated with schema checking. This is the default.
---	---

1	Check for fatal schema errors in the XML file — this setting requires more time since the XML file is checked against a WCS schema reference document accessed from the OGC server.
2	Check for fatal errors in the XML file and schema document — this setting checks both the XML file and the reference schema document for fatal errors, and requires a considerable amount of time.

VALIDATION_MODE

XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. A DTD can be embedded in an XML document or provided via a link to an external document, which must be downloaded before validation can occur. In most applications, *schemas* provide a more robust validation mechanism.

Set this keyword to one of the following values to control DTD-based validation of the XML document:

0	Turn DTD validation off — external DTDs are not loaded and the XML file is not checked for errors. Use this setting to avoid the delays associated with loading and checking an external DTD. This is the default.
1	Validate only if an embedded DTD or a link to an external DTD is provided.
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Examples

Parse a URL and then call `GetCapabilities` to return an XML file. Use a callback function to return status information about the query. See [IDLnetOGCWCS::GetCoverageOfferingBriefs](#) for an example that retrieves information needed for a `DescribeCoverage` query.

Note

You may need to replace the URL in the following example as there is no guarantee that the given OGC server will be available when you attempt to establish the connection.

```
FUNCTION ogcwcs_callback, StatusInfo, CallbackData
PRINT, StatusInfo
```

```

; Indicate all is well.
RETURN, 1

END

PRO ogc_wcs_getcapabilities_doc

; This example queries an OGC server at the following URL. Change
; the value of this variable to access a server of your choice.
url="http://data.ittvis.com:80/cgi-bin" + $
    "/mapserv.exe?MAP=/OGC_Data/WCS/wcs_demo.map" + $
    "&SERVICE=WCS&VERSION=1.0.0&REQUEST=GetCapabilities"

; Create object and define callback function. Adding /VERBOSE
; prints additional StatusInfo to the Output log.
oWcs = OBJ_NEW("IDLnetOGCWCS", $
    CALLBACK_FUNCTION="ogcwcs_callback", /VERBOSE)

; Parse the URL.
oWcs->ParseUrl, url

; Call GetCapabilities with schema checking off since this is for
; example purposes.
count = oWcs->GetCapabilities(SCHEMA_CHECKING=0)
oWcs->GetProperty, LAST_FILE=lastfile

; Show the number of returned coverage offering briefs.
PRINT, "Query returned ", $
    + STRING(count) + " coverage offering briefs"

; Cleanup.
OBJ_DESTROY, oWcs

END

```

[IDLnetOGCWCS::GetCoverageOfferingBriefs](#),
[IDLnetOGCWCS::GetServiceSection](#)

IDLnetOGCWCS::GetCoverage

The `IDLnetOGCWCS::GetCoverage` function method retrieves a data file from a remote OGC WCS server, and writes the file to disk. The file location is specified by the `COVERAGE_FILENAME` property, and will be overwritten if this property value remains unchanged between `GetCoverage` requests.

Note

The `URL_PATH` and `URL_HOSTNAME` properties must be set before requesting information from a remote WCS server. You can either set these properties manually or pass a URL to the `IDLnetOGCWCS::ParseUrl` method prior to making a request. If you are dealing with a proxy server, you must also set the `PROXY_HOSTNAME` and `PROXY_PORT` properties to the correct values.

This method returns only when one of the following occur:

- Completes retrieval of information from server
- Encounters an HTTP error
- Encounters an OGC exception
- Responds to a cancel request as specified in a callback return value

You can implement a callback to return status information during the request by setting the `CALLBACK_FUNCTION` property. You can also use a callback to cancel a request. See “Using Callbacks with the `IDLnetOGCWCS` Object” on page 5191 for details. This method will throw an error if the `GetCoverage` request fails.

Syntax

```
Result = Obj->[IDLnetOGCWCS::]GetCoverage(Coverage_Request)
```

Return Value

The return value is string containing the path to the file returned by this request or an empty string if no file was returned.

Arguments

Coverage_Request

The `Coverage_Request` argument must be a string that contains the required key-value pairs separated by the `&` character. These elements can be extracted from the

structures returned by the `IDLnetOGCWCS::GetCoverageOffering` method. The required elements are shown in the following table, and match those described in OGC Web Coverage Service (WCS) specification. See the OGC web site (www.opengeospatial.org) for specification details.

Key-value Pair	Description
COVERAGE=name	Name of the available coverage. Required. Source — in the Main Coverage Offering Structure see “CO_NAME” on page 5232.
CRS=crs_identifier	Coordinate Reference System used for the request. Required. Source — in the CRS Structure see: <ul style="list-style-type: none"> • “REQUEST_RESPONSE” on page 5244 • “REQUEST” on page 5244 • “NATIVE” on page 5244
RESPONSE_CRS=crs_identifier	Coordinate Reference System to use for the coverage response. Optional. The default is the request CRS. Source — in the CRS Structure see “RESPONSE” on page 5244.
BBOX=minx, miny, maxx, maxy, minz, maxz	Request a coverage subset as defined by the bounding box coordinate pairs, ordered according to the CRS parameter reference system. Either BBOX or TIME is required. Source — in the Spat_Dom_LonLatEnv Structure , see: <ul style="list-style-type: none"> • “POS1” on page 5236 • “POS2” on page 5236 If the WCS server supports returning a subset of the data, then the bounding box values can be any that fall inside of the bounding box.

Table 33-3: Required Elements of a GetCoverage Request

Key-value Pair	Description
<p>TIME=time1, time2, ... or TIME=min/max/res, ...</p>	<p>Request a coverage subset defined by specific time instances or intervals expressed in an extended ISO 8601 syntax. This parameter is optional if the selected layer has a default time, fixed time, or no time defined. Either BBOX or TIME is required.</p> <p>Source — in the Spat_Dom_LonLatEnv Structure, see the following fields:</p> <ul style="list-style-type: none"> • “TM_POS1” on page 5237 • “TM_POS2” on page 5237 <p>If the WCS server supports returning a subset of the data, then the time values can be any that occur within the available time span.</p>
<p>PARAMETER=val1, val2, .. or PARAMETER= min/max/res</p>	<p>(Only for range sets with compound values.) Use a constraining PARAMETER to request a subset where PARAMETER is a variable string that matches the name of a parameter listed in the selected coverage’s range description set. For example:</p> <p>band=1,5,3 (e.g., radiance values in bands 1, 5, 3) age=0/18 (e.g., counts of people with ages under 18 yrs.)</p> <p>Optional when the range component has default parameter values. Set this only if the WCS server supports optional parameters.</p>
<p>WIDTH=w (integer) HEIGHT=h (integer) [DEPTH=d (integer)]</p>	<p>Request a grid defined by integer values for width, height and depth (the number of gridpoints if a 3D grid).</p> <p>Either these parameters (including DEPTH if 3D) or RESX, RESY, and RESZ (if 3D) are required.</p> <p>See the elements in the “Spat_Dom_Grid Structure” on page 5237 in order to determine the original resolution of the data.</p>

Table 33-3: Required Elements of a GetCoverage Request (Continued)

Key-value Pair	Description
RESX=x (double) RESY=y (double) [RESZ=z (double)]	Use when requesting georectified grid coverages. Request a coverage subset defined using specific spatial resolutions along each axis of the CRS reply. Units of the values are appropriate for each axis of the CRS. Either these parameters or WIDTH, HEIGHT, and DEPTH (if a 3D grid) are required.
FORMAT=format	Define the requested output format of the coverage. This must be one of the mandatory formats. Required. Source — in the Main Coverage Offering Structure see: <ul style="list-style-type: none"> • “FORMATS” on page 5234 • “NATIVE_FORMAT” on page 5234

Table 33-3: Required Elements of a GetCoverage Request (Continued)

Keywords

None

Examples

The following example connects to an OGC server and calls GetCapabilities, GetCoverageOfferingBriefs, DescribeCoverage, GetCoverageOffering and GetCoverage to return data from the server. Elements of the structure returned by GetCoverageOffering provide the required key-value pair elements of the query defining the coverage data to return.

Note

You may need to replace the URL in the following example as there is no guarantee that the given OCG server will be available when you attempt to establish the connection.

```
FUNCTION ogcwcs_callback, StatusInfo, CallbackData

PRINT, StatusInfo

; Indicate all is well.
vCancelFlag = 1
RETURN, vCancelFlag

END
```

```

PRO ogc_wcs_getcoverage_doc

; Use the GetCoverage method to return data from an OGC server.
; The GetCoverageOffering structure provides parameters required
; for the GetCoverage request.

; This example queries an OGC server at the following URL. Change
; the value of this variable to access a server of your choice.
url="http://data.ittvis.com:80/cgi-bin" + $
    "/mapserv.exe?MAP=/OGC_Data/WCS/wcs_demo.map" + $

[IDLnetOGCWCS::GetCoverageOffering](#)

IDLnetOGCWCS::GetCoverageOffering

The IDLnetOGCWCS::GetCoverageOffering function method returns a complex structure that contains the details of a single coverage offering, one that was returned by the IDLnetOGCWCS::DescribeCoverage method request. You can return either the first coverage offering described in the XML file or a coverage identified by the INDEX keyword value.

This method will throw an error if the GetCoverageOffering call fails.

Syntax

Result = Obj->[IDLnetOGCWCS::]GetCoverageOffering([INDEX=value])

Return Value

Returns a structure containing the coverage offering details. The coverage offering structure contains strings, arrays of strings, structures, and arrays of structures.

Note

To return only the names of the coverage offerings that exist in the XML file see the DescribeCoverage method return value.

Coverage Offering Structure

The coverage offering structure is complex. Some elements in the main structure return other structures as shown in the following figure. Click on the names of any of the structures in the boxes to go to the associated reference section.

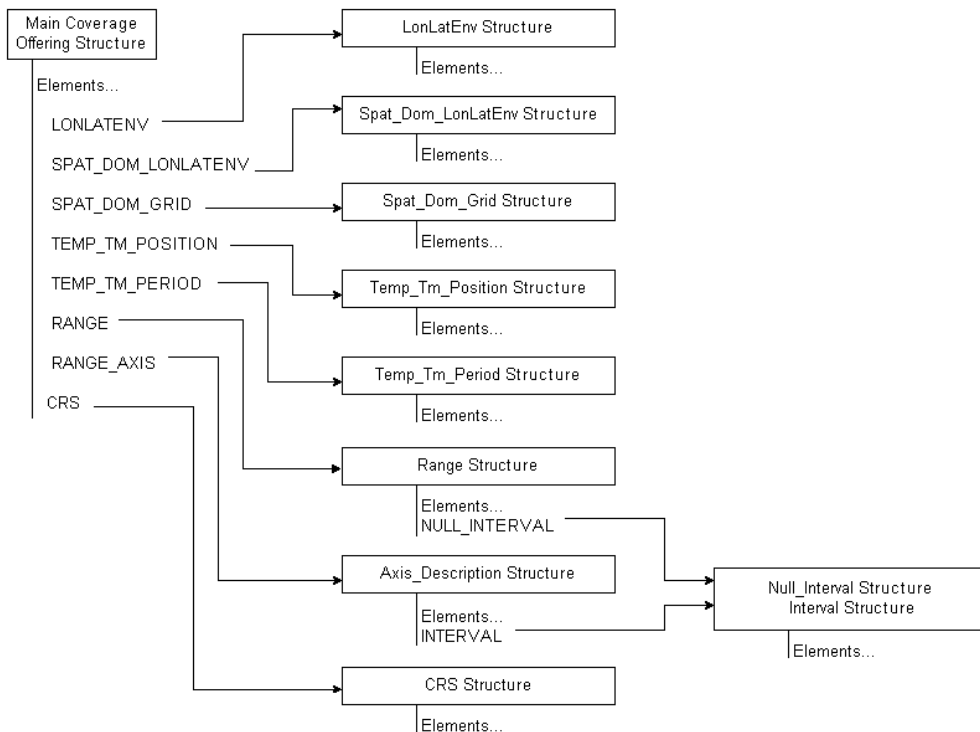

Figure 33-1: Coverage Offering Structures - Tree View

Main Coverage Offering Structure

The following table contains a list of tags found in the main level structure. All items return string values unless otherwise noted.

Field Name	Description
INDEX	A zero-based string index value provided as a convenience. This does not come from the XML file.
VERSION	XML source: <CoverageDescription><version>
UPDATE_SEQ	XML source: <CoverageDescription><updateSequence>
CO_NAME	XML source: <CoverageOffering><name>
CO_LABEL	XML source: <CoverageOffering><label>
CO_DESC	XML source: <CoverageOffering><description>
LONLATENV	XML source: <CoverageOffering><lonLatEnvelope> Returns a structure. See “LonLatEnv Structure” on page 5235 for details.
NUM_SPAT_DOM_LLES	Provides the number of <code>gml:Envelope</code> and <code>gml:EnvelopeWithTimePeriod</code> spatial domain elements as a convenience. This value is generated by IDL.
SPAT_DOM_LONLATENV	XML source: <CoverageOffering><domainSet><spatial Domain><gml:Envelope> and <CoverageOffering><domainSet><spatial Domain><gml:EnvelopeWithTimePeriod> Returns a structure. See “Spat_Dom_LonLatEnv Structure” on page 5235 for details.

Table 33-4: Coverage Offering Brief Structure

Field Name	Description
NUM_SPAT_DOM_GRIDS	Provides the number of <code>gml:Grid</code> and <code>gml:RectifiedGrid</code> spatial domain elements as a convenience. This value is generated by IDL.
SPAT_DOM_GRID	<p>XML source:</p> <pre><CoverageOffering><domainSet><spatial Domain><gml:Grid></pre> <p>and</p> <pre><CoverageOffering><domainSet><spatial Domain><gml:RectifiedGrid></pre> <p>Returns an array of structures. See “Spat_Dom_Grid Structure” on page 5237 for details.</p>
NUM_TEMP_TM_POSITIONS	Provides the number of temporal domain elements as a convenience. This value is generated by IDL.
TEMP_TM_POSITIONS	<p>XML source:</p> <pre><CoverageOffering><domainSet><spatial Domain><temporalDomain> <gml:timePosition></pre> <p>or</p> <pre><CoverageOffering><temporalDomain> <gml:timePosition></pre> <p>Returns an array of structures. See “Temp_Tm_Position Structure” on page 5239 for details.</p>
NUM_TEMP_TM_PERIODS	Provides the number of time period elements as a convenience. This value is generated by IDL.

Table 33-4: Coverage Offering Brief Structure (Continued)

Field Name	Description
TEMP_TM_PERIOD	XML source: <CoverageOffering><domainSet><spatialDomain><temporalDomain><timePeriod> or <CoverageOffering><temporalDomain><timePeriod> Returns an array of structures. See “Temp_Tm_Period Structure” on page 5240 for details.
RANGE	XML source: <CoverageOffering><rangeSet> <RangeSet> Returns a structure. See “Range Structure” on page 5241 for details.
NUM_RANGE_AXES	Provides the number of range set axis description elements as a convenience. This value is generated by IDL.
RANGE_AXIS	XML source: <CoverageOffering><rangeSet> <RangeSet><axisDescription> <AxisDescription> Returns an array of structures. See “Axis_Description Structure” on page 5242 for details.
CRS	XML source: <CoverageOffering><supportedCRSS> Returns a structure. See “CRS Structure” on page 5244 for details.
FORMATS	XML source: <CoverageOffering><supportedFormats> Returns an array of strings (0 to many).
NATIVE_FORMAT	XML source: <CoverageOffering><supportedFormats> <nativeFormat>

Table 33-4: Coverage Offering Brief Structure (Continued)

Field Name	Description
INTERPOLATION_METHOD	XML source: <CoverageOffering> <supportedInterpolations> Returns an array of strings (0 to many).
NATIVE_INTERPOLATION	XML source: <CoverageOffering> <supportedInterpolations><default>

LonLatEnv Structure

This structure is accessed through the [LONLATENV](#) field of the main coverage offering structure and contains the fields defined in the following table. All elements are strings unless otherwise noted.

Field	Description
SRS_NAME	XML source: <CoverageOffering><lonLatEnvelope><srsName>
POS1	XML source: <CoverageOffering><lonlatEnvelope><gml:pos>
DIMS1	XML source: <CoverageOffering><lonlatEnvelope><dimension>
POS2	XML source: <CoverageOffering><lonlatEnvelope><gml:pos>
DIMS2	XML source: <CoverageOffering><lonlatEnvelope><dimension>
TM_POS1	XML source: <CoverageOffering><lonlatEnvelope> <gml:timePosition>
TM_POS2	XML source: <CoverageOffering><lonlatEnvelope> <gml:timePosition>

Table 33-5: LonLatEnv Structure Fields

Spat_Dom_LonLatEnv Structure

This structure is accessed through the [SPAT_DOM_LONLATENV](#) field of the main coverage offering structure and can contain `gml:Envelope` or `gml:EnvelopeWithTimePeriod` information. Both of these are children of the `spatialDomain` node. To determine the number of structures returned, use the main

structure field, “[NUM_SPAT_DOM_LLES](#)” on page 5232. The number of structures can be 0 to many. All elements are strings unless otherwise noted.

Field	Description
SRS_NAME	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Envelope><srsName> and <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><srsName>
POS1	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Envelope><gml:pos> and <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><gml:pos>
DIMS1	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Envelope><gml:pos><dimension> and <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><gml:pos><dimension>
POS2	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Envelope><gml:pos> and <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><gml:pos>
DIMS2	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Envelope><gml:pos><dimension> and <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><gml:pos><dimension>

Table 33-6: Spat_Dom_LonLatEnv Structure Fields

Field	Description
TM_POS1	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><gml:timePosition>
TM_POS2	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:EnvelopeWithTimePeriod><gml:timePosition>

Table 33-6: *Spat_Dom_LonLatEnv Structure Fields (Continued)*

Spat_Dom_Grid Structure

This structure is accessed through the [SPAT_DOM_GRID](#) field of the main coverage offering structure and can contain `gml:Grid` or `gml:GridRectified` elements. Both of these are children of the `spatialDomain` node. To determine the number of `Spat_Dom_Grid` structures, access the [NUM_SPAT_DOM_GRIDS](#) field value. The number of structures can be 0 to many. All elements are strings unless otherwise noted.

Field	Description
RECTIFIED	Indicates whether or not the grid is rectified in a value of “Yes” or “No”. This value is generated by IDL.
DIMS	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><dimensions> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><dimensions>
SRS_NAME	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><srsName> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><srsName>

Table 33-7: *Spat_Dom_Grid and GridRectified Structure Fields*

Field	Description
LIMITS_ENV_LOW	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><gml:limits><gml:gridEnvelope> <gml:low> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><gml:limits> <gml:gridEnvelope><gml:low>
LIMITS_ENV_HIGH	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><gml:limits><gml:gridEnvelope> <gml:high> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><gml:limits> <gml:gridEnvelope><gml:high>
AXIS_NAMES	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><axisName> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><gml:origin><gml:pos> Returns an array of strings, 0 to many.
ORIGIN_POS	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><gml:origin><gml:pos> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><gml:origin><gml:pos>
OFFSET_VECTORS	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:Grid><gml:offsetVector> and <CoverageOffering><domainSet><spatialDomain> <gml:GridRectified><gml:offsetVector> Returns an array of strings, 0 to many.

Table 33-7: Spat_Dom_Grid and GridRectified Structure Fields (Continued)

Temp_Tm_Position Structure

This structure is accessed through the [TEMP_TM_POSITIONS](#) field of the main coverage offering structure and contains `gml:timePosition` elements, which are children of the `temporalDomain` node. To determine the number of `Temp_Tm_Position` structures, access the [NUM_TEMP_TM_POSITIONS](#) field value. The number of structures can be 0 to many. All elements are strings unless otherwise noted.

Field	Description
POSITION	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePosition> and <CoverageOffering><gml:temporalDomain> <gml:timePosition></pre>
FRAME	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePosition><frame> and <CoverageOffering><gml:temporalDomain> <gml:timePosition><frame></pre>
CALENDAR	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePosition> <calendar> and <CoverageOffering><gml:temporalDomain> <gml:timePosition><calendar></pre>
INDETERMINATE	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePosition> <indeterminate> and <CoverageOffering><gml:temporalDomain> <gml:timePosition><indeterminate></pre>

Table 33-8: *Temp_Tm_Position Structure Fields*

Temp_Tm_Period Structure

This structure is accessed through the `TEMP_TM_PERIOD` field of the main coverage offering structure and contains `gml:timePeriod` elements, which are children of the `temporalDomain` node. In turn, the `temporalDomain` node can be a child of the `spatialDomain` node or the `CoverageOffering` node. To determine the number of `Temp_Tm_Period` structures, access the `NUM_TEMP_TM_PERIODS` field value. The number of structures can be 0 to many. All elements are strings unless otherwise noted.

Field	Description
<code>_BEGIN</code> (underscore avoids conflict with IDL <code>BEGIN</code> keyword)	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePeriod> <beginPosition></pre> or <pre><CoverageOffering><gml:temporalDomain> <gml:timePeriod><beginPosition></pre>
<code>_END</code> (underscore avoids conflict with IDL <code>END</code> keyword)	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePeriod> <endPosition></pre> or <pre><CoverageOffering><gml:temporalDomain> <gml:timePeriod><endPosition></pre>
<code>RESOLUTION</code>	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePeriod> <timeResolution></pre> or <pre><CoverageOffering><gml:temporalDomain> <gml:timePeriod><timeResolution></pre>
<code>FRAME</code>	XML source: <pre><CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePeriod><frame></pre> or <pre><CoverageOffering><gml:temporalDomain> <gml:timePeriod><frame></pre>

Table 33-9: *Temp_Tm_Period Structure Fields*

Field	Description
CALENDAR	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePeriod><calendar> or <CoverageOffering><gml:temporalDomain> <gml:timePeriod><calendar>
INDETERMINATE	XML source: <CoverageOffering><domainSet><spatialDomain> <gml:temporalDomain><gml:timePeriod> <indeterminate> or <CoverageOffering><gml:temporalDomain> <gml:timePeriod><indeterminate>

Table 33-9: Temp_Tm_Period Structure Fields (Continued)

Range Structure

This structure is accessed through the **RANGE** field of the main coverage offering structure. All elements are strings unless otherwise noted.

Field	Description
NAME	XML source: <CoverageOffering><rangeSet><RangeSet> <name>
LABEL	XML source: <CoverageOffering><rangeSet><RangeSet> <label>
DESC	XML source: <CoverageOffering><rangeSet><RangeSet> <description>
NULL_SINGLE_VALUES	XML source: <CoverageOffering><rangeSet><RangeSet> <nullValues><singleValue> Returns an array of strings, 0 to many.

Table 33-10: Range Structure Fields

Field	Description
NUM_NULL_INTERVALS	Provides the number of interval elements as a convenience. This value is generated by IDL.
NULL_INTERVAL	<p>XML source: <CoverageOffering><rangeSet><RangeSet> <nullValues><interval></p> <p>Returns an array of structures (0 to many) where each structure contains an interval definition. See “Null_Interval and Interval Structures” on page 5243 for details.</p>

Table 33-10: Range Structure Fields (Continued)

Axis_Description Structure

This structure is accessed through the [RANGE_AXIS](#) field of the main coverage offering structure. All elements are strings unless otherwise noted.

Field	Description
NAME	<p>XML source: <CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><name></p>
LABEL	<p>XML source: <CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><label></p>
DESC	<p>XML source: <CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><description></p>
SINGLE_VALUE	<p>XML source: <CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><values> <singleValue></p> <p>Returns an array of strings, 0 to many.</p>
NUM_INTERVALS	Provides the number of interval elements as a convenience. This value is generated by IDL.

Table 33-11: Axis_Description Structure Fields

Field	Description
INTERVAL	XML source: <pre><CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><values> <interval></pre> Returns an array of structures (0 to many) where each structure contains an interval definition. See “Null_Interval and Interval Structures” on page 5243 for details.
DEFAULT	XML source: <pre><CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><default></pre>

Table 33-11: *Axis_Description Structure Fields (Continued)*

Null_Interval and Interval Structures

These structure fields are accessed through the [NULL_INTERVAL](#) field of the [“Range Structure”](#) on page 5241 and the [INTERVAL](#) field of the [“Axis_Description Structure”](#) on page 5242. All elements are strings unless otherwise noted.

Field	Description
MIN	XML source: <pre><CoverageOffering><rangeSet><RangeSet> <nullValues><interval><min></pre> or <pre><CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><values> <interval><min></pre>

Table 33-12: *Null_Interval and Interval Structure Fields*

Field	Description
MAX	XML source: <CoverageOffering><rangeSet><RangeSet> <nullValues><interval><max> or <CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><values> <interval><max>
RES	XML source: <CoverageOffering><rangeSet><RangeSet> <nullValues><interval><res> or <CoverageOffering><rangeSet><RangeSet> <axisDescription><AxisDescription><values> <interval><res>

Table 33-12: Null_Interval and Interval Structure Fields (Continued)

CRS Structure

This structure is accessed through the [CRS](#) field of the main coverage offering structure and contains coordinate reference system fields.

All elements return an array of strings, 0 to many.

Field	Description
REQUEST_RESPONSE	XML source: <CoverageOffering><supportedCRSs> <requestResponseCRSs>
REQUEST	XML source: <CoverageOffering><supportedCRSs> <requestCRSs>
RESPONSE	XML source: <CoverageOffering><supportedCRSs> <responseCRSs>
NATIVE	XML source: <CoverageOffering><supportedCRSs> <nativeCRSs>

Arguments

None

Keywords

INDEX

Set this to a zero-based integer value indicating the coverage offering to retrieve. This is useful when the [IDLnetOGCWCS::DescribeCoverage](#) request returns information for more than a single coverage offering.

Examples

See the `GetCoverage` method “[Examples](#)” on page 5225 for sample code that extracts the elements of the `GetCoverageOffering` structure that are required for a successful query.

[IDLnetOGCWCS::DescribeCoverage](#), [IDLnetOGCWCS::GetCoverage](#)

IDLnetOGCWCS::GetCoverageOfferingBriefs

| The IDLnetOGCWCS::GetCoverageOfferingBriefs function method provides access to the coverage offering briefs that were returned and parsed by the [IDLnetOGCWCS::GetCapabilities](#) method. You can return all coverage offering briefs or a subset of the briefs, which can be useful when:

- A large number of briefs would require significant amounts of memory to return all of them at a single time
- A user interface needs to display a subset of the available items

This method will throw an error if the GetCoverageOfferingBriefs call fails.

Note

Use “[IDLnetOGCWCS::GetServiceSection](#)” on page 5252 to return information related to the service section of the coverage offering briefs.

Syntax

```
Result = Obj->[IDLnetOGCWCS::]GetCoverageOfferingBriefs
    ([, COUNT=variable], [, NUMBER=value] [, INDEX=value])
```

Return Value

The return value is an array of structures containing one or more coverage offering briefs. Use the COUNT keyword to verify that briefs are available since the returned value can be zero when briefs are not available. All elements are strings unless otherwise noted.

Field Name	Description
INDEX	A zero-based string index value provided as a convenience. This does not come from the XML file.
NAME	XML source: <CoverageOfferingBrief><name>
LABEL	XML source: <CoverageOfferingBrief><label>
SRS_NAME	XML source: <CoverageOfferingBrief><lonlatEnvelope><srsName>

Table 33-14: Coverage Offering Brief Structure

DESCRIPTION	XML source: <CoverageOfferingBrief><description>
VERSION	XML source: <WCS_Capabilities><version>
UPDATE_SEQ	XML source: <WCS_Capabilities><updateSequence>

Table 33-14: Coverage Offering Brief Structure (Continued)

Arguments

None

Keywords

COUNT

Set this keyword to a variable that will contain the number of brief structures returned in this method's structure array. This value can be zero.

NUMBER

Set this keyword to the number of coverage offering briefs to return. If this keyword is not set, all briefs will be returned minus the number of those skipped up to the [INDEX](#) keyword, if it is set. If this value is zero, zero briefs will be returned. If the value is greater than the number of available briefs, then this value is ignored and the number of available briefs (COUNT) is returned.

Note

When populating a user interface, it is useful to set this keyword equal to the number of rows in the table.

INDEX

Set this keyword to the zero-based number of the first coverage offering brief to return, skipping over all preceding briefs. If this keyword is not set, all briefs will be returned. You can use this property to enable navigation through a list of briefs displayed in a user interface. For example, suppose there are 10 rows in a table. On the first call to `GetCoverageOfferingBriefs`, set this value to 0. To display the next set of values, you would set this keyword to 10 (skip the first 10 values and display the next ten).

Examples

The following code parses the URL of a ICEDS WCS server, queries its capabilities (using `GetCapabilities`) and then extracts information from the returned XML file using `GetCoverageOfferingBriefs` and `GetServiceSection`. Information is printed to the Output log.

Note

You may need to replace the URL in the following example as there is no guarantee that the given OCG server will be available when you attempt to establish the connection.

```
FUNCTION ogcwcs_callback, StatusInfo, CallbackData

PRINT, StatusInfo

; Indicate all is well.
vCancelFlag = 1
RETURN, vCancelFlag

END
```

```

PRO ogc_wcs_getcoverbriefs_doc

; Use the GetCoverageOfferingBriefs to access data returned in
; the XML file by the GetCapabilities method.

; This example queries an OGC server at the following URL. Change
; the value of this variable to access a server of your choice.
url="http://data.itervis.com:80/cgi-bin" + $
    "/mapserv.exe?MAP=/OGC_Data/WCS/wcs_demo.map" + $
    "&SERVICE=WCS&VERSION=1.0.0&REQUEST=GetCapabilities"

; Catch error.
CATCH, errorStatus
IF (errorStatus NE 0) THEN BEGIN
    CATCH, /CANCEL
    r = DIALOG_MESSAGE(!ERROR_STATE.MSG, TITLE='OGC WCS Error', $
        /ERROR)
    PRINT, !ERROR_STATE.MSG

IDLnetOGCWCS::GetProperty

The IDLnetOGCWCS::GetProperty procedure method retrieves the value of an IDLnetOGCWCS property.

Syntax

Obj->[IDLnetOGCWCS::]GetProperty [, PROPERTY=*variable*]

Arguments

None

Keywords

Any property listed under [IDLnetOGCWCS Properties](#) that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

IDLnetOGCWCS::GetServiceSection

The IDLnetOGCWCS::GetServiceSection function method returns the values found in the Service section of the XML file returned by the [IDLnetOGCWCS::GetCapabilities](#) method. This method will throw an error if the GetServiceSection call fails.

Syntax

Result = *Obj*->[IDLnetOGCWCS::]GetServiceSection()

Return Value

Returns a single structure containing Service element items or children of the Service element. Each field returns a string as follows:

Field Name	Description
NAME	Name assigned to the server by the service provider XML source: <Service><name>
LABEL	The display friendly label for the server XML source: <Service><label>
DESCRIPTION	Descriptive information about the server XML source: <Service><description>
KEYWORDS	Words to aid cataloging and searching XML source: <Service><keywords><keyword> Returns an array of strings, 0 to many.
INDIVIDUAL	Name of the responsible party XML source: <Service><responsibleParty><individualName>
ORGANIZATION	Name of the responsible organization XML source: <Service><responsibleParty><organisationName>

Table 33-15: Web Coverage Offering Service Section Structure Elements

Field Name	Description
POSITION	Position held by the responsible individual XML source: <Service><responsibleParty><positionName>
VOICE	Phone number of the responsible individual XML source: <Service><responsibleParty><contactInfo> <phone><voice>
FAX	Fax number of the responsible individual XML source: <Service><responsibleParty><contactInfo> <phone><facsimile>
DELIVERY	Delivery address of responsible individual XML source: <Service><responsibleParty><contactInfo> <address><deliveryPoint>
CITY	City portion of responsible party address XML source: <Service><responsibleParty><contactInfo> <address><city>
ADMINISTRATIVE	State or comparable portion of address XML source: <Service><responsibleParty><contactInfo> <address><administrativeArea>
POSTAL	Zip or comparable code of address XML source: <Service><responsibleParty><contactInfo> <address><postalCode>
COUNTRY	Country of responsible party XML source: <Service><responsibleParty><contactInfo> <address><country>

Table 33-15: Web Coverage Offering Service Section Structure Elements (Continued)

Field Name	Description
EMAIL	E-mail address of responsible party XML source: <Service><responsibleParty><contactInfo> <address><electronicMailAddress>
ONLINE	Online address associated with responsible party XML source: <Service><responsibleParty><contactInfo> <onlineResource>
FEES	The fees charged by the service provider. XML source: <Service><fees>
ACCESS	A list of access constraints imposed by the service provider. XML source: <Service><accessConstraints>

[IDLnetOGCWCS::GetCapabilities](#)

IDLnetOGCWCS::Init

The IDLnetOGCWCS::Init method initializes an IDLnetOGCWCS object, which provides a way to connect to and return information from a remote Open Geospatial Consortium Web Coverage Service server.

See [“Making OGC WCS Server Requests”](#) on page 5188 for instructions on how to use object methods and properties to configure and complete requests for information from a remote OGC WCS server.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLnetOGCWCS' [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLnetOGCWCS::]Init([, PROPERTY=value] ) (In a lifecycle  
method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [IDLnetOGCWCS Properties](#) that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation

using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLnetOGCWCS::ParseUrl

The IDLnetOGCWCS::ParseUrl procedure method breaks down a given, valid URL to a remote WCS server into component parts and sets the corresponding IDLnetOGCWCS properties. This method will set the following properties assuming a URL has each component:

- [URL_HOSTNAME](#)
- [URL_PATH](#)
- [URL_PORT](#)
- [URL_SCHEME](#)
- [URL_QUERY_PREFIX](#)
- [URL_QUERY_SUFFIX](#)

See “[Translating a URL into Property Values](#)” on page 5189 for more information on how URL components map to IDLnetOGCWCS properties.

Note

The [URL_PATH](#) and [URL_HOSTNAME](#) properties must be set before requesting information from a remote WCS server. You can either set these properties manually or pass a URL to this method prior to making a request.

This method will throw an error if the parsing process fails. Always use a known, working URL as the argument.

Syntax

Obj->[IDLnetOGCWCS::]ParseUrl, *URL*

Arguments

URL

A string argument containing a known, working URL to an OGC server from which data will be requested.

Note

A valid WCS server URL must minimally include `scheme://hostname/path?` where ? indicates the end of the path.

Keywords

None

Examples

Create an IDLnetOGCWCS object and call the ParseURL method to populate required properties. In this example use a URL of your choosing or input the following, entered as a single line at the command prompt when requested.

```
http://217.37.214.210/cgi-
bin/test?REQUEST=DescribeCoverage&Service=WCS&Coverage=ERA__Te
mperature
```

Note

You may need to use a different URL in the following example as there is no guarantee that the given OGC server will be available when you attempt to establish the connection.

```
PRO ogcparseurl_doc

; Create OGC WCS object.
oWcs = OBJ_NEW("IDLnetOGCWCS")

; Enter known working URL at command line to parse.
v=dialog_message("Enter URL at command prompt", /INFO)
url = ''
READ, url, PROMPT='Enter URL: '
oWcs->ParseUrl, STRING(url)

; Get properties to see how URL portions are assigned.
oWcs->GetProperty, URL_HOSTNAME=uhost, URL_PATH=upath,$
    URL_PORT=uport, URL_SCHEME=uscheme, $
    URL_QUERY_PREFIX=uprefix, URL_QUERY_SUFFIX=usuffix

PRINT, "HOST = " + uhost
PRINT, "PATH = " + upath
PRINT, "PORT = " + uport
PRINT, "SCHEME = " + uscheme
PRINT, "PREFIX = " + uprefix
PRINT, "SUFFIX = " + usuffix

; Cleanup.
OBJ_DESTROY, oWcs

END
```

Given the URL noted above, IDL prints:

```
host = 217.37.214.210
path = cgi-bin/test
port = 80
```

```
scheme = http  
prefix =  
suffix = Coverage=ERA__Temperature
```

IDLnetOGCWCS:: SetProperty

The IDLnetOGCWCS:: SetProperty procedure method sets the value of a property or group of properties for this object.

Syntax

Obj->[IDLnetOGCWCS::] SetProperty [, PROPERTY=*variable*]

Arguments

None

Keywords

Any property listed under [IDLnetOGCWCS Properties](#) that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLnetOGCWMS

An IDLnetOGCWMS object lets you access a Web Map Service (WMS) server that supports the Open Geospatial Consortium (OGC) standards. The OGC is an international group working to develop standards for the exchange of geospatial content and services including specifications for web delivery of data that combines location and geospatial information.

For additional information on IDL's WMS features, see the following sections:

- [“Web Map Service \(WMS\) Overview”](#) on page 5265
- [“Supported OGC WMS Version”](#) on page 5266
- [“Making OGC WMS Server Requests”](#) on page 5266
- [“Translating a URL into Property Values”](#) on page 5267
- [“Using Callbacks with the IDLnetOGCWMS Object”](#) on page 5269
- [“HTTP Authentication, Security and Encoding”](#) on page 5271

Note

See [“Feature Support by Operating System”](#) (Chapter 2, *What's New in IDL 7.1*) for information on which IDL platforms support the IDLnetOGCWMS object.

Note

A sample IDL program included in the IDL distribution provides a generic WMS browser that lets you peruse and request coverages from a remote OGC server. See [“Sample WMS Browser”](#) on page 5264 for details.

Superclasses

None

Creation

See [“IDLnetOGCWMS::Init”](#) on page 5330.

Properties

Objects of this class have the following properties. See “[IDLnetOGCWMS Properties](#)” on page 5273 for details on individual properties.

• AUTHENTICATION	• CALLBACK_DATA
• CALLBACK_FUNCTION	• CAPABILITIES_FILENAME
• CONNECT_TIMEOUT	• CONTENT_TYPE
• ENCODE	• FEATURE_INFO_FILENAME
• HEADERS	• LAST_FILE
• MAP_FILENAME	• PASSWORD
• PROXY_AUTHENTICATION	• PROXY_HOSTNAME
• PROXY_PASSWORD	• PROXY_PORT
• PROXY_USERNAME	• RESPONSE_HEADER
• SSL_CERTIFICATE_FILE	• SSL_VERIFY_HOST
• SSL_VERIFY_PEER	• TIMEOUT
• URL_HOSTNAME	• URL_PATH
• URL_PORT	• URL_QUERY_PREFIX
• URL_QUERY_SUFFIX	• URL_SCHEME
• USERNAME	• VERBOSE
• WMS_VERSION	

Methods

This class has the following methods:

- [IDLnetOGCWMS::Cleanup](#)
- [IDLnetOGCWMS::GetCapabilities](#)
- [IDLnetOGCWMS::GetFeatureInfo](#)
- [IDLnetOGCWMS::GetLayers](#)

- [IDLnetOGCWMS::GetMap](#)
- [IDLnetOGCWMS::GetProperty](#)
- [IDLnetOGCWMS::GetServiceSection](#)
- [IDLnetOGCWMS::Init](#)
- [IDLnetOGCWMS::ParseUrl](#)
- [IDLnetOGCWMS::SetProperty](#)

Examples

See the following methods for examples:

- [“IDLnetOGCWMS::GetLayers”](#) on page 5301
- [“IDLnetOGCWMS::GetMap”](#) on page 5320

Sample WMS Browser

The IDL distribution includes a sample program that allows you to enter a working URL to an OGC server and then call `GetCapabilities`, `GetMap` and `GetFeatureInfo` from within the user interface. You can modify property values and query characteristics to return the desired data. To run the browser program, enter `OGC_WMS` at the command line. See the browser help for more information.

Tip

You can use the example IDL OGC WMS Browser as a template for creating an application that queries a remote WMS server. This example is located in the `IDL_DIR\examples\ogc\wms` directory where `IDL_DIR` is the directory where you have installed IDL. Running the example lets you parse a known, working URL to an OGC WMS server, and then make `GetCapabilities`, `GetMap` and `GetFeatureInfo` requests. By default, returned files are written to your application user directory, a subdirectory of your home directory.

Web Map Service (WMS) Overview

A request for map data from an OGC WMS server involves three main requests: GetCapabilities, GetMap, and GetFeatureInfo. The following describes these operations in terms of the IDLnetOGCWMS object:

- **GetCapabilities** — a general query that returns information about what types of requests are allowed and available. This includes service and summary information about data collections that are contained in “layers,” which is transmitted in an XML file that is written to disk.
- **GetMap** — a request that asks for one or more specific layers containing geographic information where each layer can be individually rendered. The server returns requested layers in an image file that is written to disk.
- **GetFeatureInfo** — a request for data relating to a feature on a map identified by map coordinates. If supported by the server, the server transmits information about the feature to a file that is written to disk. There are no standards dictating the availability or content of such information.

For details on how to use the IDLnetOGCWMS object properties and methods to request and receive information from an OGC server, see “[Making OGC WMS Server Requests](#)” on page 5266. Also see “[Sample WMS Browser](#)” on page 5264 for information about the IDL OGC WMS Browser, a sample program included in the IDL distribution.

Additional OGC Web Map Service Resources

The Open Geospatial Consortium web site provides complete details on the Web Map Service protocol including the WMS specification and schema documents. You may find the following documents helpful if you need additional WMS resources. See OGC web site (www.opengeospatial.org) to search for these and other resource files.

Document	Description
Specification	OGC Web Map Service, Version 1.1.1, Ref# OGC 01-068r3, 2002-01-16 OGC Web Map Service, Version 1.3.0, Ref # OGC 04-024, 2004-08-02

Table 33-16: OGC WMS Reference Documents

Supported OGC WMS Version

This object supports version 1.1.1 and 1.3.0 of the OGC WMS standard. The IDLnetOGCWMS object conforms to the OGC WMS standard and is designed to communicate with OGC WMS compliant servers.

Note

Since this object is designed as an OGC WMS client, OGC WMS certification is not applicable. Compliance testing and certification is valid only for WMS servers.

Making OGC WMS Server Requests

This section outlines the steps required to query and return information from an OGC server. The goal is to return one or more layers as a rendered image map file. Broadly, an information request from a WMS sever requires determining what data is available from a server (layers), determining what data you want to request (the layer definition), making the request, and returning rendered map data. You then have the option to request specific information about a map feature if desired and if supported by the server.

Note

You can implement a callback to return information about the status of requests. See [“Using Callbacks with the IDLnetOGCWMS Object”](#) on page 5269 for details.

After you create an IDLnetOGCWMS object, you will need to complete the following steps:

1. Identify the WMS server. The easiest way to do this is to pass a *working* URL to the [IDLnetOGCWMS::ParseUrl](#) method, which sets the required URL_HOSTNAME and URL_PATH properties. Alternately, manually set properties related to the URL. See [“Translating a URL into Property Values”](#) on page 5267 for information on which URL components belong to which IDLnetOGCWMS properties.

Note

If dealing with secure WMS servers, see [“HTTP Authentication, Security and Encoding”](#) on page 5271 for additional information.

2. Determine what information is available on the WMS server by making a GetCapabilities request. This typically returns and parses an XML file that contains information about the available layers. See

[IDLnetOGCWMS::GetCapabilities](#) for details. You can modify the [CAPABILITIES_FILENAME](#) property to specify where the resulting file is stored.

3. Return the information contained in the layers by calling [IDLnetOGCWMS::GetLayers](#). You must call this method to return information for the specified layer(s) in an IDL structure. The `NAME` field value of this structure is required to request additional information from an OGC server using the `GetMap` method, described next. If you wish, you can also call [IDLnetOGCWMS::GetServiceSection](#) to return service information from the XML file, but this is not necessary.
4. Use [IDLnetOGCWMS::GetMap](#) to request the combination of one or more layers into a map, specifying the desired layers via the *Map_Request* argument. You can modify the [MAP_FILENAME](#) property to specify where the resulting file is stored.
5. Access the information about features in the map by calling [IDLnetOGCWMS::GetFeatureInfo](#). (The OGC WMS server may not offer this support for every layer, and there may not be information available for every feature). You can modify the [FEATURE_INFO_FILENAME](#) property to specify where the resulting file is stored.

Translating a URL into Property Values

A valid WMS server URL is required to establish communication with an OGC WMS server. Additionally, IDLnetOGCWMS URL-related property values must be set before data can be successfully requested from a OGC WMS server. Either set the required properties manually (using `SetProperty`) or pass a URL to `ParseURL`. The [IDLnetOGCWMS::ParseUrl](#) method automatically parses a given URL and sets related property values.

Note

Regardless of how properties are set, the `URL_HOSTNAME` and `URL_PATH` properties must be set before calling the `GetCapabilities`, `GetMap` or `GetFeatureInfo` methods.

The following table describes how the components of a given URL should be assigned to property values. Consider the following URL (which would typically exist on a single line):

```
http://my.hostname.com:8080/demo/cgi_path?CustomPrefix&
Version=1.1.1&SERVICE=WMS&CustomMiddle&Request=GetCapabilities&
CustomSuffix
```

Components of this URL map to properties as follows.

Property	Value
URL_SCHEME	http
URL_HOSTNAME	my.hostname.com
URL_PORT	8080
URL_PATH	demo/cgi_path
WMS_VERSION	Version=1.1.1 (or 1.3.0 but defaults to 1.1.1)
URL_QUERY_PREFIX	CustomPrefix&CustomMiddle
URL_QUERY_SUFFIX	CustomSuffix

Table 33-17: Mapping URL Components to Properties

The *query* portion of the URL passed to a WMS server (the *parameter=value* pairs following the ? character) always includes the following three parameters:

- *Version* takes its value from the WMS_VERSION property
- *Service* is set equal to “WMS” for the IDLnetOGCWMS object
- *Request* is one of “GetCapabilities” “GetMap”, or “GetFeatureInfo” depending on the method in use

These three parameters are inserted into the URL automatically by IDL; any values specified for these parameters in the URL are ignored. They are *not* included when the URL_QUERY_PREFIX or URL_QUERY_SUFFIX properties are returned by the GetProperty method. Any query parameters that precede *any* of the three required parameters will be included in the URL_QUERY_PREFIX property by the ParseURL method; other nonrequired parameters will be included in the URL_QUERY_SUFFIX property.

Note

If not specified in the URL, property values besides URL_HOSTNAME and URL_PATH are set to default values. For example, the URL_PORT property defaults to 80 and the WMS_VERSION defaults to 1.1.1.

Using Callbacks with the IDLnetOGCWMS Object

Callbacks from the IDLnetOGCWMS object provide a way to transmit information back to the caller based on the status of a request made to a remote OGC WMS server. The value returned by the callback function is then used by the IDLnetOGCWMS object to determine whether to continue or abort the request.

The IDLnetOGCWMS object lets you define functions (written in IDL) that will be called during a GetCapabilities, GetMap, or GetFeatureInfo method call. If a callback function is specified via the CALLBACK_FUNCTION property, it is called in the following circumstances:

- For the [IDLnetOGCWMS::GetCapabilities](#) method, the callback function is called each time a packet is received from the OGC WMS server. If the FROM_FILE keyword is set, the callback function is called before and after the XML file is parsed.
- For the [IDLnetOGCWMS::GetMap](#) method, the callback function is called each time a packet is received from the OGC WMS server.
- For the [IDLnetOGCWMS::GetFeatureInfo](#) method, the callback function is called each time a packet of data is received from the OGC WMS server.

All methods invoke the callback function with an array of strings indicating status as the first parameter, an array of integers containing progress information as the second parameter, and with the value (if any) specified by the CALLBACK_DATA property as the third parameter. A callback function returns a value of type Int.

Canceling a Request

The return value of the callback function should be an integer zero or one. If the return value is zero, a cancel message will be sent to the remote node. If the return value is one, the operation will continue.

Callback Routine Signature

A callback function is written in IDL and has the following signature:

```
Function Callback_Function_Name, StatusInfo, ProgressInfo,  
        CallbackData
```

where

- `Callback_Function_Name` is the name of the callback function. This value is specified as the value of the [CALLBACK_FUNCTION](#) property.

- `StatusInfo` is an array of strings that contain status information about the operation. The status strings are provided for information and human inspection rather than for programmatic processing; the exact strings included in the array will depend on numerous factors including the status of the operation and the type of OGC WMS server.
- `ProgressInfo` is an array of five 64-bit long integers that contain progress information for the transfer:
 - `ProgressInfo[0]` – Contains 1 (one) when the `ProgressInfo` array contains valid data, or 0 (zero) when the array does not contain valid data.
 - `ProgressInfo[1]` – Contains the total number of bytes to be downloaded. This array element will contain 0 (zero) when the transfer encoding is “chunked.”
 - `ProgressInfo[2]` – Contains the number of bytes that have been downloaded during the current transfer.
 - `ProgressInfo[3]` – Contains the total number of bytes to be uploaded.
 - `ProgressInfo[4]` – Contains the number of bytes that have been uploaded during the current transfer.
- `CallbackData` is the data specified via the [CALLBACK_DATA](#) property. The value of this property is passed to the callback function unmodified. If the `CALLBACK_DATA` property is unspecified, an integer zero is passed to the callback function as the value of this parameter.

The `CallbackData` parameter is useful for passing static information, such as the widget ID of a widget where the status information is displayed or a pointer to a complex data structure, from the `IDLnetOGCWMS` object to the callback routine.

For a simple example of using a callback to return additional status information, see “[IDLnetOGCWMS::GetCapabilities](#)” on page 5290. The `StatusInfo` details are printed to the Output window.

HTTP Authentication, Security and Encoding

The following sections describe the IDLnetOGCWMS object's support of HTTP protocols including:

- [“HTTP Authentication”](#)
- [“HTTP Security”](#)
- [“HTTP Encoding”](#)

HTTP Authentication

The IDLnetOGCWMS object supports the following HTTP authentication modes for WMS and proxy servers:

- Disabled—no authentication
- Basic—plain text transmission of username and password
- Digest—encrypted transmission of username and password

By default, [AUTHENTICATION](#) and [PROXY_AUTHENTICATION](#) properties are set to “Basic and Digest” option, meaning that either basic or digest authentication are supported. However, for this setting to be honored, the corresponding username and password properties must also be set:

- For authentication on an OGC server, set [USERNAME](#) and [PASSWORD](#) properties
- For authentication on a proxy server, set [PROXY_USERNAME](#) and [PROXY_PASSWORD](#) properties

HTTP Security

The IDLnetOGCWMS object also supports HTTPS through the implementation of Secure Socket Layer (SSL). With SSL encryption, all requests and responses are encrypted. When the [URL_SCHEME](#) property is set to “https”, use the [SSL_CERTIFICATE_FILE](#), [SSL_VERIFY_HOST](#), and [SSL_VERIFY_PEER](#) properties to define security-related parameters.

Note

If you receive a PRNG (Pseudo Random Number Generator) error when attempting to use HTTPS on UNIX, you need to install either `dev/random` or `dev/urandom` in order to generate secure keys.

HTTP Encoding

The `IDLnetOGCWMS` object supports compressed and encoded responses from a remote OGC WMS server. Supported encoding formats are:

- DEFLATE
- GZIP

See the [ENCODE](#) property for details.

IDLnetOGCWMS Properties

IDLnetOGCWMS objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLnetOGCWMS::Init](#).

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties.

- [AUTHENTICATION](#)
- [CALLBACK_DATA](#)
- [CALLBACK_FUNCTION](#)
- [CAPABILITIES_FILENAME](#)
- [CONNECT_TIMEOUT](#)
- [CONTENT_TYPE](#)
- [ENCODE](#)
- [FEATURE_INFO_FILENAME](#)
- [HEADERS](#)
- [LAST_FILE](#)
- [MAP_FILENAME](#)
- [PASSWORD](#)
- [PROXY_AUTHENTICATION](#)
- [PROXY_HOSTNAME](#)
- [PROXY_PASSWORD](#)
- [PROXY_PORT](#)
- [PROXY_USERNAME](#)
- [RESPONSE_HEADER](#)
- [SSL_CERTIFICATE_FILE](#)
- [SSL_VERIFY_HOST](#)
- [SSL_VERIFY_PEER](#)
- [TIMEOUT](#)
- [URL_HOSTNAME](#)
- [URL_PATH](#)
- [URL_PORT](#)
- [URL_QUERY_PREFIX](#)
- [URL_QUERY_SUFFIX](#)
- [URL_SCHEME](#)
- [USERNAME](#)
- [VERBOSE](#)
- [WMS_VERSION](#)

AUTHENTICATION

This property specifies the type of authentication used when connecting to an OGC server. Supported authentication modes are:

0	Disabled — authentication is disabled.
1	Basic only — username and password are sent as plain text.
2	Digest only — username and password are encrypted before being sent.
3	Basic and digest — either basic or digest is used depending on the mode preferred by the remote server. This is the default.

When AUTHENTICATION is set, one or both of the [USERNAME](#) and [PASSWORD](#) properties must also be set. If neither of these properties is set, this property is ignored.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CALLBACK_DATA

This property contains data that is to be passed to the function defined by the [CALLBACK_FUNCTION](#) property when a callback is initiated. The data contained in the variable is defined and set by the caller. When a callback is initiated, this data is passed, unmodified, directly to callback function. Data can be of any type supported by IDL variables including numerical, string, pointer and structure data. If this property is not set, the GetCapabilities, GetMap, and GetFeatureInfo methods will pass the integer value zero to the callback function.

Property Type	Any IDL variable		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CALLBACK_FUNCTION

This property is the name of the `.pro` code function to be called when GetCapabilities, GetMap, and GetFeatureInfo methods are retrieving information from the remote server. The function provides status information in addition to

providing a way to cancel an operation. If this property is not set, then no callbacks will be made by the previously noted methods. See [“Using Callbacks with the IDLnetOGCWMS Object”](#) on page 5269 for more information.

The default value is a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CAPABILITIES_FILENAME

The `IDLnetOGCWCS::GetCapabilities` method returns and stores an XML file that contains information about the layers available on the remote server. Set this property to define the path and filename of this file, minus the extension. The file type extension is automatically set based on the type of file downloaded (typically `.xml`). If this property stays the same between calls to `GetCapabilities`, the last file received is overwritten.

This property defaults to a file named `cap`, located in your application user directory. If a file was returned by the most recent call to the `GetCapabilities` method, the `LAST_FILE` property will contain the full path and filename of the downloaded file.

Note

Do not include a file type extension in the filename. If the retrieved file does not have the same extension as that given, the name will be appended with the file type extension of the received file (but this property will remain unchanged). For example, if you include the `.xml` extension (`cap.xml`) and the file received is an HTML file, the filename of the file on disk will be `cap.xml.html`, while this property remains `cap.xml`. Always omit the file type extension to avoid such inconsistencies.

This property cannot be set to a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONNECT_TIMEOUT

This property controls how long to wait for a successful connection to an OGC server before ending the attempt to establish a connection. The default is 180 seconds.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONTENT_TYPE

This property indicates the document type of the last file received. The value of this property is extracted from the Content-Type field of an HTTP response header.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ENCODE

This property determines if a compressed or encoded response will be requested from a remote OGC WMS server (during GetCapabilities, GetMap, and GetFeatureInfo method calls). By default, the IDLnetOGCWMS object requests an unencoded response (ENCODE=0) in order to reduce the number of bytes that need to be sent over the network.

Note

The server does not have to respond with compressed or encoded data. You can determine the encoding, if any, by examining the “Content-Encoding” header in the response. See the [VERBOSE](#) property for information on how to access such information.

Allowable values are:

Value	Description
0	No encoding — do not request an encoded response. If the server sends a compressed or encoded response even though this was not requested, the response will not be decompressed or decoded and the output file will be written with the compressed or encoded data. This is the default
1	DEFLATE encoding — request and accept DEFLATE encoding. If the server replies with an encoded response, the data is decompressed or decoded before being written to the output file.
2	GZIP encoding — request and accept GZIP encoding. If the server replies with an encoded response, the data is decompressed or decoded before being written to the output file.
3	DEFLATE and GZIP encoding — request and accept both types of encoded responses. If the server replies with an encoded response, the data is decompressed or decoded before being written to the output file.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FEATURE_INFO_FILENAME

The [IDLnetOGCWMS::GetFeatureInfo](#) method returns and stores a feature file from the WMS server. Set this property to define the path and filename of this file, minus the extension. The file type extension is automatically set based on the type of file downloaded. If this property stays the same (the path and filename are unchanged, and the same type of file is retrieved) between calls to `GetFeatureInfo`, the last file received is overwritten.

This property defaults to a file named `feature`, located in your application user directory. If a file was returned by the most recent call to the `GetFeatureInfo` method, the `LAST_FILE` property will contain the full path and filename of the downloaded file.

Note

Do not include a file type extension in the filename. If the retrieved file does not have the same extension as that given, the name will be appended with the file type extension of the received file (but this property will remain unchanged). For example, if you include the `.txt` extension (`feature.txt`) and the file received is an `.html` file, the filename of the file on disk will be `feature.txt.html`, while this property remains `feature.txt`. Always omit the file type extension to avoid such inconsistencies.

This property cannot be set to a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HEADERS

Note

This property is set automatically and need not be modified unless you have specific HTTP header information that you want included in a GET request sent to a remote WMS server.

Warning

This property is automatically set to the default value (clearing any custom header information) after a call to any `IDLnetOGCWMS::Get*` method except `GetProperty`. Clearing the `HEADERS` property prevents the inadvertent use of custom header values in future calls to `Get` methods.

Set this property to a string or array of strings containing one or more valid header fields and values separated by a colon. Each string in the string array should contain a single header field.

The HTTP header `Host`, `Accept` and `Encode` fields are set by default. To add, disable or modify headers, do one of the following:

- Add a custom header by setting this property equal to a string containing a valid header field and value or a string array containing multiple strings. This property can be called multiple times to append additional header fields to the list of existing custom header items.
- Disable an existing header by setting the HTTP header field name equal to no value (no data on the right side of the colon). For example, `HEADERS="Accept:"` disables the header field.
- Add a header without contents by setting a header field equal to an empty string. For example, `HEADERS="Accept: ' '"` clears the field contents.

Set this property to an empty string to clear all custom headers and reset default values if appropriate. For example, `HEADERS= ' '` clears all custom changes.

Note

This method cannot be used to modify the first method line of a HTTP request (typically GET or POST).

Retrieving this property will return only those headers set using this method. Use the [VERBOSE](#) keyword to see the default header information included in a request.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

LAST_FILE

This property contains the full path and filename of the file retrieved from the last successful call to one of the `GetCapabilities`, `GetFeatureInfo`, or `GetMap` methods. If the most recent call did not return a file, this property will contain a null string. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

MAP_FILENAME

The `IDLnetOGCWMS::GetMap` method returns and stores a map file containing the layers requested from the WMS server. Set this property to define the path and

filename of this file, minus the extension. The file type extension is automatically set based on the type of file downloaded. If this property stays the same (the path and filename are unchanged, and the same type of file is retrieved) between calls to GetMap, the last file received is overwritten.

This property defaults to a file named `map`, located in your application user directory. If a file was returned by the most recent call to the GetMap method, the `LAST_FILE` property will contain the full path and filename of the downloaded file.

Note

Do not include a file type extension in the filename. If the retrieved file does not have the same extension as that given, the name will be appended with the file type extension of the received file (but this property will remain unchanged). For example, if you include the `.tiff` extension (`cov.tiff`) and the file received is a `.gml` file, the filename of the file on disk will be `cov.tiff.gml`, while this property remains `cov.tiff`. Always omit the file type extension to avoid such inconsistencies.

This property cannot be set to a null string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PASSWORD

This property contains the password required for successful authentication with a secure WMS server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

PROXY_AUTHENTICATION

This property specifies the type of authentication that will be used when connecting to a proxy server. Supported authentication modes are:

0	Disabled — proxy authentication is disabled.
1	Basic only — proxy username and password are sent as plain text.
2	Digest only — proxy username and password are encrypted before being sent.
3	Basic and digest — either basic or digest is used depending on the mode preferred by the server. This is the default.

When PROXY_AUTHENTICATION is set and you are using a proxy server, the [PROXY_USERNAME](#) and [PROXY_PASSWORD](#) properties must also be set. If either of these properties are not set, then this property is ignored.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_HOSTNAME

This property specifies the hostname or IP address of the proxy server. This property must be set when connecting to an intranet or the internet through a proxy server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_PASSWORD

This property contains the password required for successful authentication with a secure proxy server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

PROXY_PORT

This property specifies the TCP/IP port that the proxy server listens to for incoming requests. The default value is “80”, the standard port for an HTTP request. This property must be set when connecting to an intranet or the internet through a proxy server.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_USERNAME

This property contains the username required for successful authentication with a secure proxy server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

RESPONSE_HEADER

This read-only property contains the HTTP response header from the last request made to an OGC WMS server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SSL_CERTIFICATE_FILE

Set this property to the full path and filename of the file containing one or more certificates to be verified with the peer when communicating with a secure server. The default location is `IDL_DIR/bin/bin.platform` directory where `IDL_DIR` is your IDL installation directory. A default bundle of Certificate Authority (CA) certificates is installed in this location. Use this property to specify the location of an alternate certificate file.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERIFY_HOST

When negotiating a SSL connection, the server sends a certificate indicating its identity. Use this property to determine whether you have connected to the expected server as follows:

0	No verification. The connection succeeds regardless of the name fields in the certificate.
1	Verify server. When this property is non-zero, the Common Name field or a Subject Alternate Name field in the certificate must match the host name in the URL (the URL_HOSTNAME property), or the connection fails. The default.

Note

To guard against a dishonest server, authenticate its certificate. See [“SSL_VERIFY_PEER”](#) on page 5284.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERIFY_PEER

SSL peer authentication depends on verification of a chain of digital signatures contained in one or more Certificate Authority (CA) certificates. See [“SSL_CERTIFICATE_FILE”](#) on page 5283 for information on the default CA certificates installed with IDL and how to supply your own certificates.

0	No verification. The connection succeeds regardless of the certificate’s authenticity.
1	Verify server. Set this property to a non-zero value to authenticate a certificate returned by a secure server. If certificate verification fails, the connection fails. The default.

Note

Certificate authentication is typically used in conjunction with server verification. See [“SSL_VERIFY_HOST”](#) on page 5283 for details.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TIMEOUT

This property controls how long to wait for the transmission from the OGC server to complete before ending the attempt. The default is 1800 seconds.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_HOSTNAME

This property specifies the host name or IP address of the remote OGC WMS server.

Note

This property and the [URL_PATH](#) property must be set before calling `GetCapabilities`, `GetMap`, or `GetFeatureInfo`. The hostname and path elements are integral components of the request that is sent to the WMS server.

You can either set this property manually or pass a URL to the [IDLnetOGCWMS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)” on page 5267 for more information. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_PATH

This property specifies the path to the remote OGC WMS server.

Note

This property and the [URL_HOSTNAME](#) property must be set before calling `GetCapabilities`, `GetMap`, or `GetFeatureInfo`. The path and hostname elements are integral components of the request that is sent to the WMS server.

You can either set this property manually or pass a URL to the [IDLnetOGCWMS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)” on page 5267 for more information. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_PORT

This property specifies the TCP/IP port at which the remote server listens for incoming requests. You can either set this property manually or pass a URL to the [IDLnetOGCWCS::ParseUrl](#) method. See “[Translating a URL into Property Values](#)”

on page 5267 for more information. The default value is “80”, the standard port for an HTTP request.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_QUERY_PREFIX

This property specifies a prefix containing additional query information that will be prepended to the main portion of a request. You can either set this property manually or pass a URL to the `IDLnetOGCWMS::ParseUrl` method. See “[Translating a URL into Property Values](#)” on page 5267 for more information. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_QUERY_SUFFIX

This property specifies a suffix containing additional query information that will be appended to the main portion of a request. See “[Translating a URL into Property Values](#)” on page 5267 for more information on this property. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_SCHEME

This property specifies the name of the protocol used to communicate with the remote WMS server when a request is made. You can either set this property

manually or pass a URL to the `IDLnetOGCWCS::ParseUrl` method. See “[Translating a URL into Property Values](#)” on page 5267 for more information. Possible values are:

String Value	Description
http	This is the default.
https	Use this setting when making a secure request and Secure Socket Layer (SSL) is supported by the remote WMS server. See SSL_CERTIFICATE_FILE , SSL_VERIFY_HOST , and SSL_VERIFY_PEER for SSL-related configuration parameters.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

USERNAME

This property contains the username required for successful authentication with a secure WMS server. The default value is an empty string.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERBOSE

Set this property to a non-zero value to return verbose connection and HTTP header information associated with an `IDLnetOGCWMS::GetCapabilities`, `IDLnetOGCWMS::GetMap`, or `IDLnetOGCWMS::GetFeatureInfo` method request. By default, this property is set to zero, and only standard information is returned.

To access this information, the `CALLBACK_FUNCTION` property must also be set. The callback function’s `StatusInfo` variable will contain:

- messages about the TCP/IP connection to the remote server
- messages about the HTTP header fields being sent to the remote server
- messages about the HTTP header fields received from the remote server

Each message is limited to 512 bytes of text.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

For a simple example of using a callback to return VERBOSE status information, see [“IDLnetOGCWMS::GetLayers”](#) on page 5301.

WMS_VERSION

This property defines the version of the OGC WMS standard supported by the IDLnetOGCWMS object. The default value is “Version=1.1.1” but “Version=1.3.0” is also an allowable value.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLnetOGCWMS::Cleanup

The IDLnetOGCWMS::Cleanup method performs all cleanup on the object. All open network connections are closed when the IDLnetOGCWMS object is destroyed.

Note

Cleanup methods are special *lifecycle* methods, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLnetOGCWMS::]Cleanup (In a lifecycle method only.)

Arguments

None

Keywords

None

Version History

6.4	Introduced
-----	------------

IDLnetOGCWMS::GetCapabilities

The `IDLnetOGCWMS::GetCapabilities` function method retrieves an XML file containing layers describing geographic information from a remote OGC WMS server, writes the file to disk, and parses the file contents before returning. The XML file is written to the location specified by the `CAPABILITIES_FILENAME` property, and will be overwritten if this property value remains unchanged between `GetCapabilities` requests.

You can parse the contents of an existing XML file by setting the `FROM_FILE` keyword. This avoids having to download the same information as that which exists on disk.

Note

The `URL_PATH` and `URL_HOSTNAME` properties must be set before requesting information from a remote WMS server. You can either set these properties manually or pass a URL to the `IDLnetOGCWMS::ParseUrl` method prior to making a request. If you are dealing with a proxy server, you must also set the `PROXY_HOSTNAME` and `PROXY_PORT` properties to the correct values.

This method returns only when one of the following occur:

- Completes retrieval and parsing of information from server
- Encounters an HTTP error
- Encounters an OGC exception
- Responds to a cancel request as specified in a callback return value

You can implement a callback to return status information during the request by setting the `CALLBACK_FUNCTION` property. You can also use a callback to cancel a request. See “Using Callbacks with the `IDLnetOGCWCS` Object” on page 5191 for details. This method will throw an error if the `GetCapabilities` request fails.

After this method returns, you must use `IDLnetOGCWMS::GetLayers` to return layer details. The `GetCapabilities` method accesses and parses the information from the server and returns a count containing the number of layers received, but does not provide immediate access to the detailed information. You can also use the `IDLnetOGCWMS::GetServiceSection` method to access information about service data contained in the XML file.

Syntax

```
Result = Obj->[IDLnetOGCWMS::]GetCapabilities
    ([, /DISABLE_INHERITANCE] [, FROM_FILE=string]
    [, SCHEMA_CHECKING=value] [, VALIDATION_MODE=value])
```

Return Value

Returns the number of layers received.

Arguments

None

Keywords

DISABLE_INHERITANCE

Set this keyword to a Boolean value indicating whether or not to disable layer inheritance as follows:

0	False - allow inheritance (the default)
1	True - disable inheritance

The OGC WMS standard specification defines which child layer tags can inherit from a parent layer. When inheritance is enabled (`DISABLE_INHERITANCE=0`), the returned layer structures will have inheritance rules applied to each layer as described in *Inheritance of Layer Values*. For example, if a child inherits its parents' layer information, the child SRS value will be composed of an array that includes all the SRS values of all parents. When the inheritance rule is "Add," duplicate values are ignored (not replicated).

FROM_FILE

Set this keyword to a string containing the full path and filename of an XML file to parse for layers and service data. This allows you use a previously downloaded capabilities file.

When you use the `FROM_FILE` keyword and the `CALLBACK_FUNCTION` property is set, status information will be returned when the XML file is first accessed and when parsing has ended. The entire file contents are parsed.

SCHEMA_CHECKING

XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, Document Type Definitions (DTDs). Schemas are typically provided via a link to an external document, which must be downloaded before validation can occur.

Set this keyword to one of the following values to control the degree of error-checking the parser should perform:

0	Turn schema checking off — the XML file is not checked for errors. Use this setting to avoid the delays associated with schema checking. This is the default.
1	Check for fatal schema errors in the XML file — this setting requires more time since the XML file is checked against a WMS schema reference document accessed from the OGC server.
2	Check for fatal errors in the XML file and schema document — this setting checks both the XML file and the reference schema document for fatal errors, and requires a considerable amount of time.

VALIDATION_MODE

XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. A DTD can be embedded in an XML document or provided via a link to an external document, which must be downloaded before validation can occur. In most applications, *schemas* provide a more robust validation mechanism.

Set this keyword to one of the following values to control DTD-based validation of the XML document:

0	Turn DTD validation off — external DTDs are not loaded and the XML file is not checked for errors. Use this setting to avoid the delays associated with loading and checking an external DTD. This is the default.
1	Validate only if an embedded DTD or a link to an external DTD is provided.
2	Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error.

Inheritance of Layer Values

The following tables (“[Number](#)” below and “[Inheritance](#)” on page 5293) describe how the child layer elements inherit parent layer elements. See the following column descriptions for details.

Number

The Number column provides information on how many times each element may appear in a layer, either explicitly or through inheritance as follows:

Value	Meaning
1	Appears exactly once in each Layer
0/1	Appears either once or not at all
0+	Appears 0 or more times
1+	Appears one or more times

Inheritance

The Inheritance column indicates whether or how the element is inherited by child Layers as follows:

Value	Meaning
No	Not inherited. If the element is defined as mandatory, each Layer element will include that element.
Replace	Value can be inherited, but if defined by child, the value is replaced.
Add	Values that may appear more than one time can be inherited from parent and added to any value(s) of the child. Any duplication by the child may be ignored.

Layer Element Inheritance in Version 1.1.1

When inheritance is enabled (DISABLE_INHERITANCE=0), use the following table to determine the type of allowable inheritance for a server supporting OGC WMS version 1.1.1.

Element	Number	Inheritance
Layer	0+	No
Name	1	No
Title	1	No
Abstract	0/1	No
KeywordList	0/1	No
Style	0+	Add
SRS	1+	Add
LatLonBoundingBox	1	Replace
BoundingBox	0+	Replace
Dimension	0+	Add
Extent	0+	Replace
Attribution	0/1	Replace
AuthorityUrl	0+	Add
Identifier	0+	No
MetadataUrl	0+	No
DataUrl	0/1	No
FeatureListUrl	0/1	No
ScaleHint	0/1	Replace

Table 33-18: Child Inheritance of Parent Elements in Version 1.1.1

Layer Element Inheritance in Version 1.3.0

When inheritance is enabled (`DISABLE_INHERITANCE=0`), use the following table to determine the type of allowable inheritance for a server supporting OGC WMS version 1.3.0.

Element	Number	Inheritance
Layer	0+	No
Name	0/1 ^a	No
Title	1	No
Abstract	0/1	No
KeywordList	0/1	No
Style	0+	Add
CRS	1+ ^b	Add
Ex_GeographicBoundingBox	1 ^b	Replace
BoundingBox	1+ ^b	Replace
Dimension	0+	Replace
Attribution	0/1	Replace
AuthorityUrl	0+	Add
Identifier	0+	No

DataUrl	0/1	No
FeatureListUrl	0/1	No
MinScaleDenominator	0/1	Replace
MaxScaleDenominator	0/1	Replace

Table 33-19: Child Inheritance of Parent Elements in Version 1.3.0

^a See “[Layer Names and Titles](#)” on page 5322 for more information.

^b May be 0 only if a value is inherited from a parent layer.

Examples

See [IDLnetOGCWMS::GetLayers](#) for an example that parses a URL and then calls `GetCapabilities` to return an XML file. A callback function is used to return status information about the query. Also see “[Sample WMS Browser](#)” on page 5264.

See Also

[IDLnetOGCWMS::GetLayers](#), [IDLnetOGCWMS::GetServiceSection](#)

IDLnetOGCWMS::GetFeatureInfo

The `IDLnetOGCWMS::GetFeatureInfo` function method retrieves a feature information file from a remote OGC WMS server and writes the file to disk. This file contains information about a specific feature. The value of the `QUERYABLE` tag in the structure returned by `IDLnetOGCWMS::GetLayers` can be used to determine if the server supports `GetFeatureInfo` for a particular layer. The OGC WMS server may not offer this support for every layer.

The feature file location is specified by the `FEATURE_INFO_FILENAME` property, and will be overwritten if this property value remains unchanged between `GetFeatureInfo` requests.

Note

The `URL_PATH` and `URL_HOSTNAME` properties must be set before requesting information from a remote WMS server. You can either set these properties manually or pass a URL to the `IDLnetOGCWMS::ParseUrl` method prior to making a request. If you are dealing with a proxy server, you must also set the `PROXY_HOSTNAME` and `PROXY_PORT` properties to the correct values.

This method returns only when one of the following occur:

- Completes retrieval of information from server
- Encounters an HTTP error
- Encounters an OGC exception
- Responds to a cancel request as specified in a callback return value

You can implement a callback to return status information during the request by setting the `CALLBACK_FUNCTION` property. You can also use a callback to cancel a request. See “Using Callbacks with the `IDLnetOGCWMS` Object” on page 5269 for details. This method will throw an error if the `GetFeatureInfo` request fails.

Syntax

```
Result = Obj->[IDLnetOGCWMS::]GetFeatureInfo(Feature_Info_Request)
```

Return Value

The return value is a string containing the path to the file returned by this request or an empty string if no file was returned.

Arguments

Feature_Info_Request

The *Feature_Info_Request* argument must be a string that contains the required request parameters separated by the & character. These elements can be extracted from the structures returned by the `IDLnetOGCWMS::GetLayers` method, and many are the same parameters used in the `IDLnetOGCWMS::GetMap` request. The required elements are shown in the following table, and match those described in the OGC Web Map Service (WMS) specification. See the OGC web site (www.opengeospatial.org) for specification details.

Parameter	Description
SRS=namespace:identifier	Spatial Reference System used in 1.1.1 requests. Required. Source — the GetMap request parameter, “SRS= namespace:identifier” on page 5321.
CRS=namespace:identifier	Spatial Reference System used in 1.3.0 requests. Required. Source — the GetMap request parameter, “CRS= namespace:identifier” on page 5321.
BBOX=minx, miny, maxx, maxy	A coverage subset as defined by the bounding box coordinate pairs defining corners (lower left, upper right), in SRS units. Required. Source — the GetMap request parameter, “BBOX=minx, miny, maxx, maxy” on page 5321.
WIDTH=output_width	Width of map image in pixels. Required. Source — the GetMap request parameter, “WIDTH=output_width” on page 5322.
HEIGHT=output_height	Height of map image in pixels. Required. Source — the GetMap request parameter, “HEIGHT=output_height” on page 5322.

Table 33-20: Required Elements of a GetFeatureInfo Request

Parameter	Description
QUERY_LAYERS=layer_list	Comma-separated list of one or more map layers. Required. Source — layer names must be one or more of the layer names specified in the LAYERS=layer_list parameter of the IDLnetOGCWMS::GetMap call.
INFO_FORMAT=format	Return format information of feature. Required. Source — in the Main Layer Structure , see “ FEATURE_FORMAT ” on page 5304.
X=pixel_column	X-coordinate of feature in pixels in map coordinate system. Valid in version 1.1.1 only. Required.
Y=pixel_row	Y-coordinate of feature in pixels in map coordinate system. Valid in version 1.1.1 only. Required.
I=pixel_column	I-coordinate of feature in pixels in map coordinate system. Valid in version 1.3.0 only. Required.
J=pixel_row	J-coordinate of feature in pixels in map coordinate system. Valid in version 1.3.0 only. Required.
FEATURE_COUNT=number	Number of features about which to return information (defaults to 1). Optional

IDLnetOGCWMS::GetLayers

The IDLnetOGCWMS::GetLayers function method provides access to the layer details that were returned and parsed by the [IDLnetOGCWMS::GetCapabilities](#) method. You can return information for all layers or a subset of the layers, which can be useful when:

- A large number of layers would require significant amounts of memory to return all of them at a single time
- A user interface needs to display a subset of the available items

Note

Use “[IDLnetOGCWMS::GetServiceSection](#)” on page 5327 to return information related to the service section of the layer information.

Syntax

```
Result = Obj->[IDLnetOGCWMS::]GetLayers ([, COUNT=variable],  
[, NUMBER=value] [, INDEX=value])
```

Return Value

The return value is an array of structures containing one or more layers. Use the COUNT keyword to verify that layers are available since the returned value can be zero when layers are not available. The layer structure contains single values, arrays of strings, and structures.

Layer Structure

The layer structure is complex. Some elements in the main structure return other structures as shown in the following figure. Click on the names of any of the structures in the boxes to go to the associated reference section.

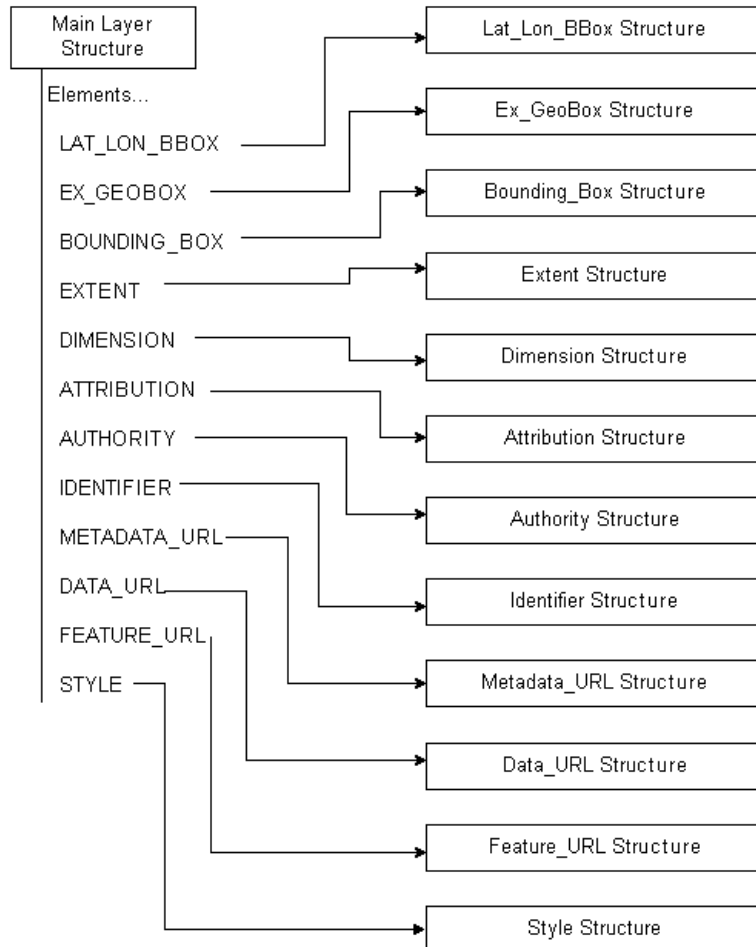

Figure 33-2: Layer Structure and Sub-structures

Main Layer Structure

The following table contains a list of tags found in the main level Layer structure. All items return string values unless otherwise noted. All tags are valid in versions 1.1.1 and 1.3.0 unless otherwise noted.

Field Name	Description
LAYER	Contains the zero-based layer number as a convenience. Layers are numbered sequentially as they are encountered in the XML file returned by GetCapabilities. This value is generated by IDL.
PARENT	Contains the layer number of the parent of this child level as a convenience. If the layer is at the root level, the value is -1. This value is generated by IDL.
LEVEL	Contains the nesting level of the layer as a convenience. Layers at the root level have a LEVEL value of 1, children of the root level have a value of 2. This value increases with increasing nesting level and is generated by IDL.

UPDATE_SEQUENCE	1.1.1 XML source: <WMT_MS_Capabilities><updatesequence> 1.3.0 XML source: <WMS_Capabilities><updatesequence>
NAME	1.1.1, 1.3.0 XML source: <layer><name>
TITLE	1.1.1, 1.3.0 XML source: <layer><title>
ABSTRACT	1.1.1, 1.3.0 XML source: <layer><abstract>

Table 33-21: Layer Structure

Field Name	Description
NUM_MAP_FORMAT	Provides the number of map formats as a convenience. This value is generated by IDL.
MAP_FORMAT	Array of strings (0 to many). 1.1.1, 1.3.0 XML source: <capability><request><getmap><format>
NUM_FEATURE_FORMAT	Provides the number of feature formats as a convenience. This value is generated by IDL.
FEATURE_FORMAT	Array of strings (0 to many). 1.1.1, 1.3.0 XML source: <capability><request><getfeatureinfo><format>
NUM_KEYWORD	Provides the number of keywords as a convenience. This value is generated by IDL.
KEYWORD	Array of strings (0 to many). 1.1.1, 1.3.0 XML source: <layer><keywordlist><keyword>
NUM_SRS	Provides the number of SRS elements as a convenience. This value is generated by IDL. Valid in version 1.1.1 only (version 1.3.0 always returns 0).
SRS	Array of strings (0 to many). 1.1.1 XML source: <layer><srs>
NUM_CRS	Provides the number of CRS elements as a convenience. This value is generated by IDL. Valid in version 1.3.0 only (version 1.1.1 always returns 0).
CRS	Array of strings (0 to many). 1.3.0 XML source: <layer><crs>

Table 33-21: Layer Structure (Continued)

Field Name	Description
LAT_LON_BBOX	Returns a structure. See “Lat_Lon_Bbox Structure” on page 5308 for details. 1.1.1 XML source: <layer><latlonboundingbox> Valid in version 1.1.1 only.
EX_GEOBOX	Returns a structure. See “Ex_GeoBox Structure” on page 5309 for details. 1.3.0 XML source: <layer><ex_geographicboundingbox> Valid in version 1.3.0 only.
NUM_BOUNDING_BOX	Provides the number of BOUNDING_BOX elements as a convenience. This value is generated by IDL.
BOUNDING_BOX	Returns an array of structures (0 to many). See “Bounding_Box Structure” on page 5309 for details. 1.1.1, 1.3.0 XML source: <layer><bounding_box>
NUM_EXTENT	Provides the number of EXTENT elements as a convenience. This value is generated by IDL. Valid in version 1.1.1 only (version 1.3.0 always returns 0).
EXTENT	Returns an array of structures (0 to many). See “Extent Structure” on page 5310 for details. 1.1.1 XML source: <layer><extent>
NUM_DIMENSION	Provides the number of DIMENSION elements as a convenience. This value is generated by IDL.
DIMENSION	Returns an array of structures (0 to many). See “Dimension Structure” on page 5310 for details. 1.1.1, 1.3.0 XML source: <layer><dimension>

Table 33-21: Layer Structure (Continued)

Field Name	Description
ATTRIBUTION	Structure. See “Attribution Structure” on page 5311 for details. 1.1.1, 1.3.0 XML source: <layer><attribution>
NUM_AUTHORITY	Provides the number of AUTHORITY elements as a convenience. This value is generated by IDL.
AUTHORITY	Returns an array of structures (0 to many). See “Authority Structure” on page 5312 for details. 1.1.1, 1.3.0 XML source: <layer><authority>
NUM_IDENTIFIER	Provides the number of IDENTIFIER elements as a convenience. This value is generated by IDL.
IDENTIFIER	Returns an array of structures (0 to many). See “Identifier Structure” on page 5312 for details. 1.1.1, 1.3.0 XML source: <layer><identifier>
NUM_METADATA_URL	Provides the number of METADATA_URL elements as a convenience. This value is generated by IDL.
METADATA_URL	Returns an array of structures (0 to many). See “Metadata_URL Structure” on page 5313 for details. 1.1.1, 1.3.0 XML source: <layer><metadataurl>
NUM_DATA_URL	Provides the number of DATA_URL elements as a convenience. This value is generated by IDL.

STYLE_ONLINE	1.1.1, 1.3.0 XML source: <layer><style><styleurl><onlineresource>

Table 33-33: Style Structure Fields

Arguments

None

Keywords

COUNT

Set this keyword to a variable that will contain the number of layer structures returned in this method's structure array. This value can be zero.

NUMBER

Set this keyword to the number of layers to return. If this keyword is not set, all layers will be returned minus the number of those skipped up to the [INDEX](#) keyword, if it is set. If this value is zero, zero layers will be returned. If the value is greater than the number of available layers, then this value is ignored and the number of available layers (COUNT) is returned.

Note

When populating a user interface, it is useful to set this keyword equal to the number of rows in the table.

INDEX

Set this keyword to the zero-based index of the first layer to return, skipping over all preceding layers. If this keyword is not set, all layers will be returned. You can use this property to enable navigation through a list of layers displayed in a user interface. For example, suppose there are 10 rows in a table. On the first call to `GetLayers`, set this value to 0 and `NUMBER` to 10. To display the next set of values, you would set this keyword to 10 (skip the first 10 values and display the next ten).

Examples

The following code parses the URL of WMS server, queries its capabilities (using `GetCapabilities`) and then extracts information from the returned XML file using `GetLayers` and `GetServiceSection`. Information is printed to the IDL Output Log.

Note

You may need to replace the URL in the following example as there is no guarantee that the given OGC server will be available when you attempt to establish the connection.

```
FUNCTION ogcwms_callback, StatusInfo, CallbackData  
  
PRINT, StatusInfo
```

```

; Indicate all is well.
vCancelFlag = 1
RETURN, vCancelFlag

END

PRO ogc_wms_getlayers_doc

; Use the GetLayers method to access data returned in
; the XML file by the GetCapabilities method.

; This example queries an OGC server at the following URL. Change
; the value of this variable to access a server of your choice.
url="http://data.ittvis.com:80/cgi-bin/mapserv.exe?" + $
    "map=/OGC_Data/WMS/wms_demo.map&service=WMS"

; Catch error.
CATCH, errorStatus
IF (errorStatus NE 0) THEN BEGIN
    CATCH,/CANCEL
    PRINT, !ERROR_STATE.MSG
    IF OBJ_VALID(oWms) THEN OBJ_DESTROY, oWms
    RETURN
ENDIF

; Create an IDLnetOGCWMS object and parse a known, working URL
; to set mandatory properties. Use /VERBOSE to show additional
; information.
oWms = OBJ_NEW("IDLnetOGCWMS", $
    CALLBACK_FUNCTION="ogcwms_callback", /VERBOSE)
oWms->ParseUrl, url

; Return and parse a description of all data holdings on
; the WMS server.
count = oWMS->GetCapabilities()

; Make sure the server returned some layers.
If (count NE 0) THEN BEGIN

    ; Use the GetLayers method to translate the
    ; parsed XML data into an array of IDL structures. The NAME
    ; field of this structure is used to identify what layer
    ; to request data for from the server.
    layerStruct = oWMS->GetLayers $

[IDLnetOGCWMS::GetCapabilities](#), [IDLnetOGCWMS::GetServiceSection](#)

IDLnetOGCWMS::GetMap

The IDLnetOGCWMS::GetMap function method retrieves a map file from a remote OGC WCS server, and writes the file to disk. The file location is specified by the [MAP_FILENAME](#) property, and will be overwritten if this property value remains unchanged between GetMap requests.

Note

The [URL_PATH](#) and [URL_HOSTNAME](#) properties must be set before requesting information from a remote WCS server. You can either set these properties manually or pass a URL to the [IDLnetOGCWMS::ParseUrl](#) method prior to making a request. If you are dealing with a proxy server, you must also set the [PROXY_HOSTNAME](#) and [PROXY_PORT](#) properties to the correct values.

This method returns only when one of the following occur:

- Completes retrieval of information from server
- Encounters an HTTP error
- Encounters an OGC exception
- Responds to a cancel request as specified in a callback return value

You can implement a callback to return status information during the request by setting the [CALLBACK_FUNCTION](#) property. You can also use a callback to cancel a request. See “Using Callbacks with the IDLnetOGCWMS Object” on page 5269 for details. This method will throw an error if the GetMap request fails.

Syntax

```
Result = Obj->[IDLnetOGCWMS::]GetMap(Map_Request)
```

Return Value

The return value is a string containing the path to the file returned by this request or an empty string if no file was returned.

Arguments

Map_Request

The *Map_Request* argument must be a string that contains the required parameters separated by the & character. These elements can be extracted from the structures

returned by the [IDLnetOGCWMS::GetLayers](#) method. The required and optional elements are shown in the following table, and match those described in OGC Web Map Service (WMS) specification. See the OGC web site (www.opengeospatial.org) for specification details.

Request Parameter	Description
LAYERS=layer_list	<p>Comma-separated list of one or more map layers. Required.</p> <p>Source — in the Main Layer Structure see “NAME” on page 5303. Also see “Layer Names and Titles” on page 5322 below for more information.</p>
STYLES=styles_list	<p>Comma-separated list of one rendering style per requested layer. If set to “Style=” then the server will use the default style of the first layer requested. Required.</p> <p>Source — in the Style Structure see “NAME” on page 5315.</p>
SRS=namespace:identifier	<p>Spatial Reference System used in 1.1.1 requests. Required.</p> <p>Source — in the Main Layer Structure see “SRS” on page 5304.</p>
CRS=namespace:identifier	<p>Spatial Reference System used in 1.3.0 requests. Required.</p> <p>Source — in the Main Layer Structure see “CRS” on page 5304.</p>
BBOX=minx, miny, maxx, maxy	<p>Request a coverage subset as defined by the bounding box coordinate pairs defining corners (lower left, upper right), in SRS or CRS units. Required.</p> <p>Source — in the Main Layer Structure, see one of the following:</p> <ul style="list-style-type: none"> • “LAT_LON_BBOX” on page 5305 (version 1.1.1) • “EX_GEOBOX” on page 5305 (version 1.3.0) • “BOUNDING_BOX” on page 5305 (version 1.1.1, 1.3.0)

Table 33-34: Required and Optional Elements of a GetMap Request

Request Parameter	Description
WIDTH=output_width	Width of map image in pixels. Required.
HEIGHT=output_height	Height of map image in pixels. Required.
FORMAT= output_format	Output format of map. Required. Source — in the Main Layer Structure , see “MAP_FORMAT” on page 5304.
TRANSPARENT= TRUE FALSE	Background transparency of map. Default is false. Optional.
BG_COLOR= color_value	Hexadecimal RGB color value for the background color (default=0xFFFFFFFF). Optional.
TIME=time	Time value of layer desired in UTC format. Optional.
ELEVATION=elevation	Elevation of layer desired. Refer to section on Handling Multi-dimensional Datasets in the OGC WMS standard specification for details. Optional.
Other sample dimension(s)	Value of other dimensions as appropriate. Optional.

Table 33-34: Required and Optional Elements of a GetMap Request

Layer Names and Titles

If, and only if, a layer has a [NAME](#), then that map layer can be requested using that NAME in the [LAYERS=layer_list](#) parameter of the *Map_Request* argument. A layer that contains a NAME element is referred to as a “named layer.” If the layer has a [TITLE](#) but no NAME (see “[TITLE](#)” on page 5303), then that layer is only a category title for all the layers nested within and cannot be requested. You need to access the names of the internal layers to request the corresponding maps. If a containing category does have a NAME, you can use this name to request all of the nested layers at one time. For example, a parent layer “Roads” may have children “Interstates” and “State Highways” and allow the user to request either child individually or both together. The NAME element is not inherited by child layers.

Keywords

None

Examples

The following example connects to an OGC server and calls `GetCapabilities`, `GetLayers`, and `GetMap` to return data from the server. Elements of the structure returned by `GetLayers` provide the required request parameters of the query defining the map file to return.

Note

You may need to replace the URL in the following example as there is no guarantee that the given OGC server will be available when you attempt to establish the connection.

```

;-----
FUNCTION ogc_wms_status_callback, status, data
    PRINT, status
    RETURN, 1
END

;-----
PRO ogc_wms_GetMap_example
    compile_opt idl2
    ; Catch all errors and display an error dialog.
    CATCH, errorStatus
    IF (errorStatus NE 0) THEN BEGIN
        CATCH, /CANCEL
        PRINT, !error_state.msg
        RETURN
    ENDIF

    ; Create a new OGC WMS object.
    owms = OBJ_NEW('idlnetogcwms')

    ; Set a callback so we can see some status messages
    owms->SetProperty, CALLBACK_FUNCTION = 'ogc_wms_status_callback'

    ; Get required property values by parsing URL.
    url = 'http://igskmncngs056.cr.usgs.gov/wmsconnector/' + $
        'com.esri.wms.Esrimap/world?'
    owms->ParseURL, url

    ; Determine what information is available.
    count = owms->GetCapabilities()

    ; Make sure server returned layers.
    IF count EQ 0 THEN BEGIN
        void = $
            DIALOG_MESSAGE('No information available from WMS server')
    
```

```

        RETURN
    ENDIF

    ; Get a single second level entry.
    xlayer = owms->GetLayers(INDEX=1, NUMBER=1, COUNT=cnt)

    ; Get name.
    vLayerName = xlayer[0].name

    ; Get style.
    vStyle = ''
    IF (xlayer[0].num_style NE 0) THEN BEGIN
        vStyle = xlayer[0].style[0].name
    ENDIF

    ; Determine spatial reference system.
    IF (xlayer[0].version EQ '1.3.0') THEN BEGIN
        vCrs = xlayer[0].crs
    ENDIF ELSE BEGIN
        vCrs = xlayer[0].srs
    ENDELSE

    ; Get a bounding box
    vBBox =    xlayer[0].bounding_box[0].minx + $
              ', ' + xlayer[0].bounding_box[0].miny + $
              ', ' + xlayer[0].bounding_box[0].maxx + $
              ', ' + xlayer[0].bounding_box[0].maxy

    ; Get map format.
    IF (xlayer[0].num_map_format NE 0) THEN BEGIN
        vMapFmt = xlayer[0].map_format
    ENDIF

    ; Hard-code width and height.
    width = '500'
    height = '500'

    ; Create layer query string of required request elements.
    queryString = 'LAYERS=' + vLayerName
    queryString = queryString + '&STYLES=' + vStyle
    queryString = queryString + '&SRS=' + vCrs
    queryString = queryString + '&BBOX=' + $
        STRCOMPRESS(vBBox, /REMOVE_ALL)
    queryString = queryString + '&WIDTH=' + width
    queryString = queryString + '&HEIGHT=' + height
    queryString = queryString + '&FORMAT=' + vMapFmt

    ; Submit request for first file.
    mapFile = owms->GetMap(queryString[0])

```

```
    ; Print location of map file.  
    PRINT, 'file retrieved = ', mapfile  
    OBJ_DESTROY, owms  
  
    ; Scale the map image data into byte range and  
    ; open in the iImage iTool.  
    imgData = READ_IMAGE(mapfile)  
    iImage, BYTSCL(imgData)  
END
```

IDLnetOGCWMS::GetProperty

The IDLnetOGCWMS::GetProperty procedure method retrieves the value of an IDLnetOGCWMS property.

Syntax

Obj->[IDLnetOGCWMS::](#)GetProperty [, PROPERTY=*variable*]

Arguments

None

Keywords

Any property listed under [IDLnetOGCWMS Properties](#) that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

IDLnetOGCWMS::GetServiceSection

The IDLnetOGCWMS::GetServiceSection function method returns the values found in the Service section of the XML file returned by the [IDLnetOGCWMS::GetCapabilities](#) method.

Syntax

Result = *Obj*->[IDLnetOGCWMS:]GetServiceSection()

Return Value

Returns a single structure containing Service element items. Each field returns a string unless otherwise noted as follows:

Field Name	Description
NAME	1.1.1, 1.3.0 XML source: <service><name>
TITLE	1.1.1, 1.3.0 XML source: <service><title>
ABSTRACT	1.1.1, 1.3.0 XML source: <service><abstract>
NUM_KEYWORD	Provides the number of KEYWORD elements as a convenience. This value is generated by IDL.
KEYWORD	Array of strings (0 to many). 1.1.1, 1.3.0 XML source: <service><keywordlist><keyword>
ONLINE	1.1.1, 1.3.0 XML source: <service><onlineresource>
PERSON	1.1.1, 1.3.0 XML source: <service><contactinformation> <contactpersonprimary><contactperson>
ORGANIZATION	1.1.1, 1.3.0 XML source: <service><contactinformation> <contactpersonprimary><contactorganization>
POSITION	1.1.1, 1.3.0 XML source: <service><contactinformation><contactposition>

Table 33-35: OGC WMS Service Section
Structure Elements

Field Name	Description
ADDRESS_TYPE	1.1.1, 1.3.0 XML source: <service><contactinformation><contactaddress> <addresstype>
ADDRESS	1.1.1, 1.3.0 XML source: <service><contactinformation> <contact address><address>
CITY	1.1.1, 1.3.0 XML source: <service><contactinformation> <contact address><city>
STATE	1.1.1, 1.3.0 XML source: <service><contactinformation> <contact address><stateorprovince>
POSTAL_CODE	1.1.1, 1.3.0 XML source: <service><contactinformation> <contact address><postcode>
COUNTRY	1.1.1, 1.3.0 XML source: <service><contactinformation> <contact address><country>
VOICE	1.1.1, 1.3.0 XML source: <service><contactinformation> <contactvoicetelephone>
FAX	1.1.1, 1.3.0 XML source: <service><contactinformation> <contactfacsimiletelephone>
EMAIL	1.1.1, 1.3.0 XML source: <service><contactinformation> <contactelectronicmailaddress>
FEES	1.1.1, 1.3.0 XML source: <service><fees>
ACCESS	1.1.1, 1.3.0 XML source: <service><access>
LAYER_LIMIT	1.3.0 XML source: <service><layerlimit> Valid only in 1.3.0 (if set then this value is the number of layers that can be requested in a GetMap request). In 1.1.1, this is always equal to an empty string.

Table 33-35: OGC WMS Service Section Structure Elements (Continued)

Field Name	Description
MAX_WIDTH	1.3.0 XML source: <service><maxwidth> Valid only in 1.3.0 (if set then this value is the max width that can be used in a GetMap request). In 1.1.1, this is always equal to an empty string.
MAX_HEIGHT	1.3.0 XML source: <service><maxheight> Valid only in 1.3.0 (if set then this value is the max height that can be used in a GetMap request). In 1.1.1, this is always equal to an empty string.

[IDLnetOGCWMS::GetCapabilities](#)

IDLnetOGCWMS::Init

The IDLnetOGCWMS::Init method initializes an IDLnetOGCWMS object, which provides a way to connect to and return information from a remote Open Geospatial Consortium Web Map Service server.

See “[Making OGC WMS Server Requests](#)” on page 5266 for instructions on how to use object methods and properties to configure and complete requests for information from a remote OGC WMS server.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW( 'IDLnetOGCWMS' [, PROPERTY=value] )
```

or

```
Result = Obj->[IDLnetOGCWMS::]Init([, PROPERTY=value] ) (In a lifecycle  
method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [IDLnetOGCWMS Properties](#) that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation

using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLnetOGCWMS::ParseUrl

The IDLnetOGCWMS::ParseUrl procedure method breaks down a given, valid URL to a remote WMS server into component parts and sets the corresponding IDLnetOGCWMS properties. This method will set the following properties assuming a URL has each component:

- [URL_HOSTNAME](#)
- [URL_PATH](#)
- [URL_PORT](#)
- [URL_SCHEME](#)
- [URL_QUERY_PREFIX](#)
- [URL_QUERY_SUFFIX](#)

See “[Translating a URL into Property Values](#)” on page 5267 for more information on how URL components map to IDLnetOGCWMS properties.

Note

The [URL_PATH](#) and [URL_HOSTNAME](#) properties must be set before requesting information from a remote WMS server. You can either set these properties manually or pass a URL to this method prior to making a request.

This method will throw an error if the parsing process fails. Always use a known, working URL as the argument.

Syntax

Obj->[IDLnetOGCWMS::]ParseUrl, *URL*

Arguments

URL

A string argument containing a known, working URL to an OGC server from which data will be requested.

Note

A valid WMS server URL must minimally include `scheme://hostname/path?` where ? indicates the end of the path.

Keywords

None

Examples

Create an IDLnetOGCWMS object and call the ParseURL method to populate required properties. In this example use a URL of your choosing or input the following, entered as a single line at the command prompt when requested.

```
http://mapserv2.esrin.esa.it/cubestor/cubeserv/cubeserv.cgi?
```

```
PRO ogcparseurl_doc

; Create OGC WMS object.
oWms = OBJ_NEW("IDLnetOGCWMS")

; Enter known working URL at command line to parse.
url = ''
READ, url, PROMPT='Enter URL: '
oWms->ParseUrl, STRING(url)

; Get properties to see how URL portions are assigned.
oWms->GetProperty, URL_HOSTNAME=uhost, URL_PATH=upath,$
    URL_PORT=uport, URL_SCHEME=uscheme

PRINT, ""
PRINT, "HOST = " + uhost
PRINT, "PATH = " + upath
PRINT, "PORT = " + uport
PRINT, "SCHEME = " + uscheme

; Cleanup.
OBJ_DESTROY, oWms

END
```

Given the URL noted above, IDL prints:

```
HOST = mapserv2.esrin.esa.it
PATH = cubestor/cubeserv/cubeserv.cgi
PORT = 80
SCHEME = http
```

IDLnetOGCWMS:: SetProperty

The IDLnetOGCWMS:: SetProperty procedure method sets the value of a property or group of properties for this object.

Syntax

Obj->[IDLnetOGCWMS::] SetProperty [, PROPERTY=*variable*]

Arguments

None

Keywords

Any property listed under [IDLnetOGCWMS Properties](#) that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLnetURL

An IDLnetURL object allows IDL to act as a client to an HTTP or FTP server. The object handles:

- Opening a connection to a remote HTTP or FTP server.
- Creating and sending HTTP requests to the remote HTTP or FTP server.
- Receiving responses from the remote HTTP or FTP server.
- Receiving and writing large data files to disk at a user-specified location.

For additional information, see the following sections:

- [“Overview of the IDLnetURL Object”](#) on page 5338
- [“Using Callbacks with the IDLnetURL Object”](#) on page 5343

Superclasses

None.

Creation

See [“IDLnetURL::Init”](#) on page 5388.

Properties

Objects of this class have the following properties. See [“IDLnetURL Properties”](#) on page 5356 for details on individual properties.

• AUTHENTICATION	• CALLBACK_DATA
• CALLBACK_FUNCTION	• CONNECT_TIMEOUT
• CONTENT_TYPE	• ENCODE
• FTP_CONNECTION_MODE	• HEADERS
• PROXY_AUTHENTICATION	• PROXY_HOSTNAME
• PROXY_PASSWORD	• PROXY_PORT
• PROXY_USERNAME	• RESPONSE_CODE
• RESPONSE_FILENAME	• RESPONSE_HEADER

• SSL_CERTIFICATE_FILE	• SSL_VERIFY_HOST
• SSL_VERIFY_PEER	• SSL_VERSION
• TIMEOUT	• URL_HOSTNAME
• URL_PASSWORD	• URL_PATH
• URL_PORT	• URL_QUERY
• URL_SCHEME	• URL_USERNAME
• VERBOSE	

Methods

This class has the following methods:

- [IDLnetURL::Cleanup](#)
- [IDLnetURL::CloseConnections](#)
- [IDLnetURL::FtpCommand](#)
- [IDLnetURL::Get](#)
- [IDLnetURL::GetFtpDirList](#)
- [IDLnetURL::GetProperty](#)
- [IDLnetURL::Init](#)
- [IDLnetURL::Put](#)
- [IDLnetURL::SetProperty](#)

Examples

See the following methods for examples:

- [“IDLnetURL::FtpCommand”](#) on page 5373
- [“IDLnetURL::Get”](#) on page 5378
- [“IDLnetURL::GetFtpDirList”](#) on page 5383
- [“IDLnetURL::Put”](#) on page 5389

Overview of the IDLnetURL Object

The following sections give a general overview of the IDLnetURL object's capabilities.

HTTP Functionality

The IDLnetURL object enables the following HTTP-related tasks:

- Allows IDL to act as a HTTP client node.
- Allows IDL to act as a HTTP SSL client node.
- Issues Get requests to retrieve data from a remote HTTP server and place it in a buffer or file.
- Issues Put requests to move data from a buffer or file to a remote HTTP server.
- Issues Post requests to move data from a buffer or file to a remote HTTP server.
- Encrypts all data to and from a remote HTTP server with SSL.
- Compresses and decompresses data to and from a remote HTTP server.
- Supports Basic and Digest authentication modes.
- Supports customizing HTTP headers that are later sent to the remote HTTP server.
- Returns the HTTP response code and HTTP response header to the user.
- Provides status callbacks so the user can monitor call progress.
- Requests can be cancelled if the user chooses not to wait for a complete reply.

FTP Functionality

The IDLnetURL object enables the following FTP-related tasks:

- Allows IDL to act as a FTP client node.
- Allows IDL to act as a FTP SSL client node.
- Issues Get requests to retrieve data from a remote FTP server to a buffer or file.
- Issues Put requests to move data from a buffer or file to a remote FTP server.
- Issues Dir requests to retrieve directory listings from a remote FTP server.
- Issues commands (Delete, Make dir, and so on) to a remote FTP server.

- Encrypts all data to and from a remote FTP server with SSL.
- Supports authentication (logging into a remote FTP server).
- Returns the FTP response code and FTP response replies to the user.
- Provides status callbacks so the user can monitor call progress.
- Requests can be cancelled if the user chooses not to wait for a complete reply.
- Supports custom commands that are sent to the remote FTP server.
- Supports both Active and Passive mode connections.

HTTP Authentication Modes

The IDLnetURL object supports Disabled, Basic, and Digest HTTP authentication modes. It also supports authenticating with a remote HTTP or FTP server, and with proxy servers. The username and password can be set for both a remote HTTP or FTP server, and for a proxy server.

FTP Authentication

The IDLnetURL object supports logging in to a remote FTP server. A username and password can be set prior to connecting to a remote FTP server.

Secure HTTP

The IDLnetURL object supports the HTTPS protocol by implementing a secure socket layer (SSL). Secure HTTP ensures that all requests and responses are encrypted. To activate SSL, set the URL_SCHEME property to 'https'.

Secure FTP

The IDLnetURL object supports implicit and explicit SSL, which ensure that all requests and responses are encrypted. An FTP server may support implicit SSL, explicit SSL, or both.

Warning

Different FTP servers provide different responses when SSL authentication is not available. IDL attempts to catch these responses and generate errors if the FTP server does not support SSL, but there may be cases when IDL makes a non-SSL connection even when an SSL connection is requested. If you are not sure that the FTP server you are connecting to supports SSL, view the complete response headers to check that the connection is being made using SSL.

Explicit SSL is activated by setting the `FTP_EXPLICIT_SSL` keyword in the `Get`, `Put`, `GetFtpDirList`, and `FtpCommand` methods. Implicit SSL is activated by setting the scheme to `'ftps'`.

Note

Implicit SSL has been deprecated.

SSL Protocol Versions

By default, the `IDLnetURL` object supports automatic determination of the SSL protocol that is supported by the remote HTTP or FTP server. If the remote server does not support automatic determination of the SSL protocol version, you can direct the object to use a specific version with the `SSL_VERSION` property. The `IDLnetURL` object supports protocol versions TLS v1, SSL v2, and SSL v3. TLS v1 supersedes all previous versions of the SSL protocols.

HTTP Encoding

The `IDLnetURL` object supports compressed/encoded responses from a remote HTTP server, as well as the deflate and GZIP encoding formats. Refer to the description of the [ENCODE](#) property for details.

Proxies

The `IDLnetURL` object supports proxies. When the object utilizes a proxy, the [PROXY_HOSTNAME](#) and [PROXY_PORT](#) properties must be set.

Connection Caching

The `IDLnetURL` object caches up to five existing connections to remote HTTP or FTP servers. Once a connection is established to a remote server, the connection is reused on subsequent transactions with the remote server. Reusing a connection can save time because the connect, login, and SSL handshake information does not need to be repeated.

Use the [IDLnetURL::CloseConnections](#) method to close a connection. Typically, a remote server closes an existing connection after a period of no activity. When this occurs, the closed connection is removed from the existing connections list. Closing a connection using the `CloseConnections` method is useful for changing login information, enabling or disabling SSL, starting a new set of transactions on the FTP or HTTP server, and so on for the next transaction with the server.

Mapping URL Components to IDLnetURL Properties

Table 33-36 shows how the components of a URL map to IDLnetURL properties. Set these properties by calling the SetProperty method.

Note

You can use the [PARSE_URL](#) function to break up a URL into its component strings, which can then be passed to [IDLnetURL::SetProperty](#) method.

A URL has the following composition:

```
URL_SCHEME://URL_USERNAME:URL_PASSWORD@URL_HOST:URL_PORT/URL_PATH?
URL_QUERY
```

For example:

```
http://me:mypw@host.com:8080/project/data/get_data.cgi?dataset=cli
mate&date=01012006
```

IDLnetURL Property	Value
URL_SCHEME	'http' (the default), 'https', 'ftp', or 'ftps' (The string "://" is appended to URL_SCHEME)
URL_USERNAME	Any string. The character ":" is appended if URL_PASSWORD is supplied; otherwise the character "@" is appended. The null string is the default.
URL_PASSWORD	Any string. The character "@" is appended. The null string is the default.
URL_HOST	my.hostname.com The null string is the default.
URL_PORT	8080 The default is 80. The ":" character is prepended to URL_PORT if it is not null.

Table 33-36: IDLnetURL object URL properties.

IDLnetURL Property	Value
URL_PATH	demo/index.html The null string is the default. The '/' character is prepended to URL_PATH if it is not null.
URL_QUERY	Parm1=value1&Parm2=value2& (and so on). The null string is the default. The '?' character is prepended to URL_QUERY if it is not null.

Table 33-36: IDLnetURL object URL properties.

Using Callbacks with the IDLnetURL Object

Callbacks from the IDLnetURL object provide a way to transmit information back to the caller based on the status of a request made to a HTTP or FTP server. The value returned by the callback function is then used by the IDLnetURL object to determine whether to continue or abort the request.

The caller must set the callback function property to receive callbacks from a method. The callback is made to an IDL function, which takes IDL variables as input parameters.

Note

The callback method is intended to provide status and progress information. The callback should not be used to process the incoming or outgoing data. Any data processing must occur after the Get, Put, GetFtpDirList, or FtpCommand methods have returned.

The IDLnetURL object lets you define functions that are called during a Get or Put method call. If a callback function is specified with the CALLBACK_FUNCTION property, it is called in the following circumstances:

- For the `IDLnetURL::Get` method, the callback function is called each time a packet is received from the HTTP or FTP server.
- For the `IDLnetURL::Put` method, the callback function is called each time a packet of data is sent to the HTTP or FTP server.
- For the `IDLnetURL::GetFtpDirList` method, the callback function is called each time a list of files is retrieved.
- For the `IDLnetURL::FtpCommand` method, the callback function is called each time an FTP command is executed.

All methods invoke the callback function with an array of strings indicating status as the first parameter, an array of integers containing progress information as the second parameter, and with the value (if any) specified by the CALLBACK_DATA property as the third parameter. A callback function returns a value of type Int.

Canceling a Request

The return value of the callback function should be an integer zero or one. If the return value is zero, a cancel message will be sent to the remote node. If the return value is one, the operation will continue.

Callback Routine Signature

A callback function is written in IDL and has the following format:

```
Function Callback_Function_Name, StatusInfo, ProgressInfo,
    CallbackData
...
return vCancelFlag
```

where

- `Callback_Function_Name` is the name of the callback function. This value is specified by the [CALLBACK_FUNCTION](#) property.
- `StatusInfo` is the first input parameter. It is an array of IDL strings that contains status information about the Get or Put. When the caller is a user interface (UI), the UI typically displays the string array in a text widget.
- `ProgressInfo` is the second input parameter, and is an array of signed 64-bit values (type Long64) that contains progress information:
 - `ProgressInfo[0]` – Contains 1 (one) when the `ProgressInfo` array contains valid data, or 0 (zero) when the array does not contain valid data.
 - `ProgressInfo[1]` – The download total used when doing a HTTP Get or FTP Get. This value is 0 when doing a HTTP Get and the transfer encoding is chunked.
 - `ProgressInfo[2]` – Contains the number of bytes that have been downloaded during the current HTTP or FTP get.
 - `ProgressInfo[3]` – Contains the total number of bytes to be uploaded during a HTTP Put, HTTP Post, or FTP Put.
 - `ProgressInfo[4]` – Contains the number of bytes currently uploaded during the HTTP Put, HTTP Post, or FTP Put.
- `CallbackData` is the `CALLBACK_DATA` property that can be set prior to calling the Get, Put, GetFtpDirList, or FtpCommand method. This property is passed into the callback function unmodified, and the contents of the property are determined by the user. When the caller is a UI, the callback data typically contains the ID of a text widget that displays the status information strings. If the `CALLBACK_DATA` property is not set, its value is undefined.
- The return value is of type Int, and can be used to cancel the Get, Put, GetFtpDirList, or FtpCommand operation. See [“Cancelling a Request”](#) on page 5191 for more information.

HTTP and FTP Response Codes

The following tables list the response codes stored in the `RESPONSE_CODE` property for the last HTTP or FTP request sent to the remote server. See [“RESPONSE_CODE”](#) on page 5363 for more information about the property that holds these values.

The following table lists the error response codes generated by the `IDLnetURL` object:

Code	Code Number	Description
<code>UNSUPPORTED_PROTOCOL</code>	1	The URL you passed uses an unsupported protocol. The problem might be an unused compile-time option or a misspelled protocol string.
<code>FAILED_INIT</code>	2	Very early initialization code failed. This is likely an internal error or problem.
<code>URL_MALFORMAT</code>	3	The URL was not properly formatted.
<code>URL_MALFORMAT_USER</code>	4	Not used.
<code>COULDNT_RESOLVE_PROXY</code>	5	The given proxy host could not be resolved.
<code>COULDNT_RESOLVE_HOST</code>	6	The given remote host was not resolved.
<code>COULDNT_CONNECT</code>	7	Failed to connect to host or proxy.
<code>FTP_WEIRD_SERVER_REPLY</code>	8	After connecting to an FTP server, the <code>IDLnetURL</code> object received a strange or bad reply. The remote server is probably not an OK FTP server.
<code>FTP_ACCESS_DENIED</code>	9	A service was denied by the FTP server due to lack of access. When a login fails, this is not returned.

Code	Code Number	Description
FTP_USER_PASSWORD_INCORRECT	10	This is never returned.
FTP_WEIRD_PASS_REPLY	11	After sending the FTP password to the server, an unexpected code was received.
FTP_WEIRD_USER_REPLY	12	After sending a user name to the FTP server, an unexpected code was received.
FTP_WEIRD_PASV_REPLY	13	The IDLnetURL object did not receive a sensible result from the server in response to either a PASV or EPSV command.
FTP_WEIRD_227_FORMAT	14	FTP servers return a 227-line as a response to a PASV command. This code is returned if the IDLnetURL object fails to parse that line.
FTP_CANT_GET_HOST	15	Indicates an internal failure when looking up the host used for the new connection.
FTP_CANT_RECONNECT	16	A bad return code for either the PASV or EPSV command was sent by the FTP server, preventing the IDLnetURL object from continuing.
FTP_COULDNT_SET_BINARY	17	An error was received when trying to set the transfer mode to binary.
PARTIAL_FILE	18	A file transfer was shorter or larger than expected. This happens when the server first reports an expected transfer size, and then delivers data that doesn't match the previously-given size.

Code	Code Number	Description
FTP_COULDNT_RETR_FILE	19	Either the server returned a weird reply to a RETR command, or a zero-byte transfer was completed.
FTP_WRITE_ERROR	20	After a completed file transfer, the FTP server did not send a proper "transfer successful" code.
FTP_QUOTE_ERROR	21	When sending custom QUOTE commands to the remote server, one of the commands returned an error code of 400 or higher.
HTTP_RETURNED_ERROR	22	This is returned if CURLOPT_FAILONERROR is TRUE and the HTTP server returns an error code that is \geq 400.
WRITE_ERROR	23	An error occurred when writing received data to a local file, or an error was returned from a write callback.
MALFORMAT_USER	24	Not used
FTP_COULDNT_STOR_FILE	25	The server denied the STOR operation. The error buffer usually contains the server's explanation.
READ_ERROR	26	There was a problem reading a local file, or the read callback returned an error.
OUT_OF_MEMORY	27	A memory allocation request failed. This is not a good thing.
OPERATION_TIMEOUTED	28	The specified time-out period was exceeded.
FTP_COULDNT_SET_ASCII	29	Failed to set ASCII transfer type (TYPE A).

Code	Code Number	Description
FTP_PORT_FAILED	30	The FTP PORT command returned an error. This often happens when the address is improper.
FTP_COULDNT_USE_REST	31	The FTP REST command failed.
FTP_COULDNT_GET_SIZE	32	The FTP SIZE command failed. SIZE is not a fundamental FTP command; it is an extension and not all servers support it. This is not a surprising error.
HTTP_RANGE_ERROR	33	The HTTP server does not support or accept range requests.
HTTP_POST_ERROR	34	This is an odd error that mainly occurs due to internal confusion.
SSL_CONNECT_ERROR	35	A problem occurred somewhere in the SSL/TLS handshake. Check the error buffer for more information.
AD_DOWNLOAD_RESUME	36	An FTP resume was attempted beyond the file size.
FILE_COULDNT_READ_FILE	37	A file in the format of "FILE://" couldn't be opened, most likely because the file path is invalid. File permissions may also be the culprit.
LDAP_CANNOT_BIND	38	The LDAP bind operation failed.
LDAP_SEARCH_FAILED	39	LDAP search failed.
LIBRARY_NOT_FOUND	40	The LDAP library was not found.
FUNCTION_NOT_FOUND	41	A required LDAP function was not found.
ABORTED_BY_CALLBACK	42	A callback returned an abort code.

Code	Code Number	Description
BAD_FUNCTION_ARGUMENT	43	Internal error. A function was called with a bad parameter.
BAD_CALLING_ORDER	44	Not used.
INTERFACE_FAILED	45	A specified outgoing interface could not be used. Use CURLOPT_INTERFACE to set the interface for outgoing connections.
BAD_PASSWORD_ENTERED	46	Not used.
TOO_MANY_REDIRECTS	47	Too many redirects. When following redirects, IDL hit the maximum amount. Set your limit with CURLOPT_MAXREDIRS.
UNKNOWN_TELNET_OPTION	48	An option set with CURLOPT_TELNETOPTIONS was not recognized.
TELNET_OPTION_SYNTAX	49	A TELNET option string was malformed.
OBSOLETE	50	Not used.
SSL_PEER_CERTIFICATE	51	The remote server's SSL certificate is invalid.
GOT_NOTHING	52	The server returned nothing. In certain circumstances, getting nothing is considered an error.
SSL_ENGINE_NOTFOUND	53	The specified crypto engine wasn't found.
SSL_ENGINE_SETFAILED	54	Can not set the selected SSL crypto engine as the default.
SEND_ERROR	55	Sending network data failed.
RECV_ERROR	56	Failure in receiving network data.

Code	Code Number	Description
SHARE_IN_USE	57	Share is in use.
SSL_CERTPROBLEM	58	There is a problem with the local certificate.
SSL_CIPHER	59	Could not use the specified cipher.
SSL_CACERT	60	The peer certificate cannot be authenticated with known CA certificates.
BAD_CONTENT_ENCODING	61	Unrecognized transfer encoding.
LDAP_INVALID_URL	62	Invalid LDAP URL.
FILESIZE_EXCEEDED	63	Maximum file size exceeded.
FTP_SSL_FAILED	64	Requested FTP SSL level failed.
SEND_FAIL_REWIND	65	Sending the data required rewinding the data to retransmit, but the rewind operation failed.
SSL_ENGINE_INITFAILED	66	Failed to initialize the SSL engine.
LOGIN_DENIED	67	The user password (or similar) was not accepted and the login failed.
TFTP_NOTFOUND	68	File not found on TFTP server.
TFTP_PERM	69	There is a permission problem on the TFTP server.
TFTP_DISKFULL	70	TFTP server is out of disk space.
TFTP_ILLEGAL	71	Illegal TFTP operation.
TFTP_UNKNOWNID	72	Unknown TFTP transfer ID.
TFTP_EXISTS	73	TFTP file already exists.
TFTP_NOSUCHUSER	74	No such TFTP user.

The following table lists all the HTTP response codes. Refer to <http://www.w3.org/> for detailed specifications.

Code Number	Code
1xx	Informational
100	Continue
101	Switching Protocols
2xx	Success
200	OK
201	Created
202	Accepted
203	Non-Authoritative Information
204	No Content
205	Reset Content
206	Partial Content
207	Multi-Status
3xx	Redirection
300	Multiple Choices
301	Moved Permanently
302	Found
303	See Other (since HTTP/1.1)
304	Not Modified
305	Use Proxy (since HTTP/1.1)
306	
307	Temporary Redirect (since HTTP/1.1)
4xx	Client Error
400	Bad Request

Code Number	Code
401	Unauthorized
402	Payment Required
403	Forbidden
404	Not Found
405	Method Not Allowed
406	Not Acceptable
407	Proxy Authentication Required
408	Request Timeout
409	Conflict
410	Gone
411	Length Required
412	Precondition Failed
413	Request Entity Too Large
414	Request-URI Too Long
415	Unsupported Media Type
416	Requested Range Not Satisfiable
417	Expectation Failed
449	Retry
5xx	Server Error
500	Internal Server Error
501	Not Implemented
502	Bad Gateway
503	Service Unavailable
504	Gateway Timeout

Code Number	Code
505	HTTP Version Not Supported
509	Bandwidth Limit Exceeded

The following table lists all the FTP response codes. Refer to <http://www.w3.org/> for detailed specifications.

Code Number	Code
110	Restart marker reply.
120	Service ready in nnn minutes.
125	Data connection already open; transfer starting.
150	File status okay; about to open data connection.
200	Command okay.
202	Command not implemented, superfluous at this site.
211	System status, or system help reply.
212	Directory status.
213	File status.
214	Help message.
215	NAME system type.
220	Service ready for new user.
221	Service closing control connection.
225	Data connection open; no transfer in progress.
226	Closing data connection.
227	Entering Passive Mode (h1,h2,h3,h4,p1,p2).
230	User logged in, proceed.
250	Requested file action okay, completed.
257	"PATHNAME" created.

Code Number	Code
331	User name okay, need password.
332	Need account for login.
350	Requested file action pending further information.
421	Service not available, closing control connection.
425	Can't open data connection.
426	Connection closed; transfer aborted.
450	Requested file action not taken.
451	Requested action aborted: local error in processing.
452	Requested action not taken.
500	Syntax error, command unrecognized.
501	Syntax error in parameters or arguments.
502	Command not implemented.
503	Bad sequence of commands.
504	Command not implemented for that parameter.
530	Not logged in.
532	Need account for storing files.
550	Requested action not taken.
551	Requested action aborted: page type unknown.
552	Requested file action aborted.
553	Requested action not taken. File name not allowed.

Example of Using Widgets with IDLnetURL

The following example creates a widget-based dialog that connects to a OGC WCS server and allows you to download files located on the server. The dialog automatically points to the ITT Visual Information Solutions FTP server, which contains several sample files for download.

Example Code

See `idlneturl_widget.pro`, located in the `examples/doc/objects` subdirectory of the IDL distribution, for the example code listing. View the file in an IDL editor window by entering `.EDIT idlneturl_widget.pro.` at the IDL Command Line.

IDLnetURL Properties

IDLnetURL objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set with `IDLnetURL::Init`.

Note

For a discussion of the property description tables that follow, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties:

• AUTHENTICATION	• CALLBACK_DATA
• CALLBACK_FUNCTION	• CONNECT_TIMEOUT
• CONTENT_TYPE	• ENCODE
• FTP_CONNECTION_MODE	• HEADERS
• PROXY_AUTHENTICATION	• PROXY_HOSTNAME
• PROXY_PASSWORD	• PROXY_PORT
• PROXY_USERNAME	• RESPONSE_CODE
• RESPONSE_FILENAME	• RESPONSE_HEADER
• SSL_CERTIFICATE_FILE	• SSL_VERIFY_HOST
• SSL_VERIFY_PEER	• SSL_VERSION
• TIMEOUT	• URL_HOSTNAME
• URL_PASSWORD	• URL_PATH
• URL_PORT	• URL_QUERY
• URL_SCHEME	• URL_USERNAME
• VERBOSE	

AUTHENTICATION

This property determines the type of authentication used when connecting to a remote server. If `AUTHENTICATION` is enabled, the server expects to receive both a username and password, either specified through the `URL_USERNAME` and `URL_PASSWORD` properties, or in a URL specified explicitly in the Get or Put

method. IDL does not check to make sure the username and password are provided, but the remote server may generate an error if they are not.

Supported authentication modes are:

0	Disabled	Authentication is disabled. This is the default.
1	Basic Only	Username and password are sent as plain text.
2	Digest Only	Username and password are encrypted before being sent.
3	Basic and Digest	Either basic or digest is used depending on the mode preferred by the remote server.

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CALLBACK_DATA

This property contains data that is passed to the caller when a callback is made. The data contained in this variable is defined and set by the caller. The variable is passed, unmodified, directly to the caller as a parameter in the callback function. If this property is not set, the Get, Put, GetFtpDirList, and FtpCommand methods pass an undefined variable.

Property Type	Any IDL variable		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CALLBACK_FUNCTION

This property is the name of the IDL function to be called when the Get, Put, GetFtpDirList, and FtpCommand methods are retrieving information from the remote server. The callbacks provide feedback to the user about the ongoing operation, as well as provide a method to cancel an ongoing operation. If this property is not set, the Get, Put, GetFtpDirList, and FtpCommand methods will not make a callback to

the IDL caller. For information on creating a callback function, see [“Using Callbacks with the IDLnetURL Object”](#) on page 5343

The default value is a null string

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONNECT_TIMEOUT

This property controls how long, in seconds, the object will wait for a successful connection to a remote HTTP or FTP server. The default is 180 seconds.

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

CONTENT_TYPE

This property contains the type of the last document received when an HTTP Get request was issued. This property only applies to an HTTP Get call, and is set from the partial contents of the Content-Type field found in an HTTP response header.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

ENCODE

This property determines if a compressed/encoded response is requested from a remote HTTP server. By default, the IDLnetURL object requests that the server respond with compressed/encoded data to reduce the number of bytes sent over the network. The server does not have to respond with compressed/encoded data even if this object requests such a response. If the server does respond with compressed/encoded data, the server also sets the Content-Encoding header in the response to the type of compression/encoding used.

The valid property values are:

0	<p>Do not request an encoded response.</p> <p>“Accept-Encoding:” is not sent in the request.</p> <p>If the server still sends a compressed/encoded response (even though not requested), the response is not decompressed/decoded and the output file is written with the compressed/encoded data.</p>
1	<p>Request and accept a deflate response.</p> <p>“Accept-Encoding: deflate” is added to the request header.</p> <p>If the server replies with a compressed/encoded response, the response is decompressed/decoded before being written to the output file.</p>
2	<p>Request and accept a GZIP response.</p> <p>“Accept-Encoding: gzip” is added to the request header.</p> <p>If the server replies with a compressed/encoded response, the response is decompressed/decoded before being written to the output file.</p>
3	<p>Request and accept deflate or gzip responses.</p> <p>“Accept-Encoding: deflate, gzip” is added to the request header.</p> <p>If the server replies with a compressed/encoded response, the response is decompressed/decoded before being written to the output file.</p> <p>This is the default value.</p>

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

FTP_CONNECTION_MODE

This property determines whether FTP uses an active or passive connection mode. During an FTP transaction there are two connections — a control channel and a data channel — established with the remote FTP server.

In passive mode, the IDL client creates both the control and data connections to the remote FTP server. In active mode, the IDL client only creates the control channel to the remote FTP server, and the remote FTP server creates the data channel connection to the IDL client. The security settings on your network may prevent active mode, passive mode, or both from working. If active mode fails, try passive mode. If passive mode fails, enable FTP transactions on your network.

The valid property values are:

0	Passive
1	Active (this is the default)

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

HEADERS

Note

This property is set automatically and need not be modified unless you have specific HTTP header information that you want included in a request sent to an HTTP server. This property is ignored if the URL scheme is not HTTP or HTTPS.

Warning

This property is automatically set to the default value (clearing any custom header information) after a call to either the `IDLnetURL::Get` or the `IDLnetURL::Put` method. Clearing the HEADERS property prevents the inadvertent use of custom header values in future calls to these methods.

Set this property to a string or array of strings containing one or more valid header fields and content values separated by a colon. Each string in the string array should contain a single header field. Set this property to an empty string (") to clear any existing custom headers.

If you add a custom header with no contents ('Accept:', for example, has no data on the right side of the colon), the internally-used header is disabled. This property allows you to add new headers, and replace and remove internal headers.

To add a header with no contents, set the contents to two single quotes: (``). For example:

```
MyHeader: ''
```

Note

The first line in an HTTP request usually looks something like

```
GET / HTTP/1.1
```

This line is not a header, and should not be included in any specification of the HEADERS property. Including lines that are not of the form

```
Header : value
```

will result in an invalid HTTP request.

Retrieving the value of the HEADERS property using the GetProperty method only returns the headers that have been explicitly set by the user; GetProperty calls do not return the headers that are automatically set when this property is not set or is explicitly set to the null string. To see the headers that are sent in the request, along with the request itself, set the [VERBOSE](#) property.

The following are examples of some HTTP headers that are automatically set for the user:

```
Host: motherlode.rsi.edu
Accept: */*
```

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_AUTHENTICATION

This property determines the type of authentication used when connecting to a proxy server. When authentication is enabled, the PROXY_USERNAME and PROXY_PASSWORD properties must be set. If these properties are not set, the PROXY_AUTHENTICATION property is ignored.

The following authentication modes are supported:

0	Disabled	Proxy authentication is disabled. This is the default.
1	Basic Only	The PROXY_USERNAME and PROXY_PASSWORD properties are sent as plain text.
2	Digest Only	The PROXY_USERNAME and PROXY_PASSWORD properties are encrypted before being sent.
3	Basic and Digest	Either the basic or digest mode can be used, depending upon the remote server's preference.

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_HOSTNAME

This property holds a proxy server name, which can be a host name or a numeric IP address. PROXY_HOSTNAME is used when connecting to an intranet or the Internet through a proxy.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_PASSWORD

This property is used when authenticating with a proxy server.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

PROXY_PORT

This property value is the TCP/IP port that the proxy server monitors for incoming requests. The default value is 80 (the standard HTTP port).

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

PROXY_USERNAME

This property is used when authenticating with a proxy server.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

RESPONSE_CODE

This property contains the HTTP/FTP response code for the last HTTP or FTP request sent to the remote server. It can be useful to examine the value of this property when an error has occurred. See [“HTTP and FTP Response Codes”](#) on page 5345 for a listing of common response codes.

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RESPONSE_FILENAME

This property contains the name of an error response file sent when a transmission error occurs. If no error has occurred, this property will contain a null string. This property will also contain a null string if a transmission error occurs, but no error file is received from the remote server.

Note

This property should only be used after catching an error.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

RESPONSE_HEADER

This property contains the HTTP or FTP response header for the last request sent to the remote HTTP or FTP server. It can be useful to examine the value of this property when an error has occurred.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: No	Registered: No

SSL_CERTIFICATE_FILE

This property is a string containing the fully-qualified path to a file containing one or more SSL certificates that verify the peer. IDL automatically installs a default bundle of CA certificates. The default value is the location of the certificates installed along with IDL (`<IDL_DIR>/bin/bin.<platform>/ca-bundle.crt`).

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERIFY_HOST

This property specifies whether the IDLnetURL object should verify the authenticity of the server certificate. When negotiating an SSL connection, the server sends a certificate indicating its identity. When `SSL_VERIFY_HOST` is 0, the connection succeeds regardless of what the certificate contains. When this property is non-zero (the default), the certificate must indicate that the server is your intended destination, or the connection fails.

The IDLnetURL object decides the server is the intended destination when the Common Name field or a Subject Alternate Name field in the certificate matches the host name in the destination URL.

Note

The server could be lying about its identity. To spot a dishonest server, refer to [SSL_VERIFY_PEER](#).

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERIFY_PEER

This property specifies whether the IDLnetURL object should verify the authenticity of the peer's SSL certificate. When negotiating an SSL connection, the server sends a certificate proving its identity. The object verifies whether the certificate is authentic (that is, that you can trust that the server is who the certificate says it is). This trust is based on a chain of digital signatures, rooted in certification authority (CA) certificates you supply. IDL installs a default bundle of CA certificates, and you can specify alternate certificates with the [SSL_CERTIFICATE_FILE](#) property.

When this property is nonzero (the default) and the verification fails to prove that the certificate is authentic, the connection fails. When this property is zero, the connection always succeeds. Authenticating the certificate is not (by itself) very useful. You typically want to ensure that the server, as authenticated by its certificate, is the server you want to communicate with (use the [SSL_VERIFY_HOST](#) property to do that).

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

SSL_VERSION

This property determines what version of the SSL/TLS protocol to use. The valid values for this property are:

0	Automatic	Automatically determines the correct protocol version of SSL to use. The default value works with most remote HTTP or FTP servers. If the remote HTTP or FTP server does not support automatic determination of the protocol version, set this property to a specific version that is supported by the remote HTTP or FTP server. This is the default.
1	TLS Version 1	Use Transport Layer Security (TLS) version 1. TLS supersedes SSL.
2	SSL Version 2	Use Secure Socket Layer (SSL) version 2.
3	SSL Version 3	Use Secure Socket Layer (SSL) version 3.

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

TIMEOUT

This property controls how long, in seconds, the object waits for the entire transfer from a remote HTTP or FTP server to complete. The default is 1800 seconds.

Property Type	Int		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_HOSTNAME

This property contains the name of the remote HTTP or FTP server, and can be a host name or IP address. Refer to [“Mapping URL Components to IDLnetURL Properties”](#) on page 5341 for details on how to pull a host name from a URL.

Note

This and all other URL_* properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_PASSWORD

This property is used when authenticating with a remote HTTP or FTP server. The value can be any string. The character “@” is appended. Refer to “[Mapping URL Components to IDLnetURL Properties](#)” on page 5341 for details on how to pull a path from a URL.

Note

This and all other URL_* properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: No	Set: Yes	Init: Yes	Registered: No

URL_PATH

This value is the full path to the network resource to be retrieved by the Get method, the full path to the directory where an uploaded file is to be placed by the Put method, the path to the directory for which the directory listing is to be retrieved by the GetFtpDirList method, or the path to the directory in which the specified command is to be executed by the FtpCommand method.

If the value is not a null string, IDL prepends the “/” character.

Refer to “[Mapping URL Components to IDLnetURL Properties](#)” on page 5341 for details on how to extract the path from a URL.

Note

This and all other “URL_” properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_PORT

This value is the TCP/IP port that the remote HTTP or FTP server monitors for incoming requests. Refer to “[Mapping URL Components to IDLnetURL Properties](#)” on page 5341 for details on how to pull a path from a URL. The default is port 80 (the standard port for HTTP connections).

Note

This and all other URL_* properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_QUERY

This value represents the portion of a URL that follows the “?” character when constructing the URL. If this value is not a null string, IDL prepends the “?” character.

Refer to “[Mapping URL Components to IDLnetURL Properties](#)” on page 5341 for details on how to pull a path from a URL.

Note

This and all other URL_* properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_SCHEME

This property contains the name of the protocol used to communicate with the remote server. The values are “http” (the default), “https”, “ftp”, and “ftps”. IDL automatically appends the string “:/" to the end of this property. Refer to [“Mapping URL Components to IDLnetURL Properties”](#) on page 5341 for details on how to pull a path from a URL.

Note

This and all other URL_* properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

URL_USERNAME

This property is used when authenticating with a remote HTTP or FTP server. The value can be any string. The string “:” is appended if URL_PASSWORD is supplied; otherwise, the string “@” is appended.

Refer to [“Mapping URL Components to IDLnetURL Properties”](#) on page 5341 for details on how to pull a path from a URL.

Note

This and all other URL_* properties are ignored if the URL keyword is specified explicitly in calls to the Get, Put, GetFtpDirList, and FtpCommand methods.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

VERBOSE

When this property is set in conjunction with the [CALLBACK_FUNCTION](#) property, the information contained in the statusInfo parameter of the callback function includes the following messages:

Message Type	Description
Info	Messages concerning the TCP/IP connection to the remote server
Header Out	Messages concerning the HTTP header fields or FTP commands being sent to the remote server
Header In	Messages concerning the HTTP header fields or FTP command responses received from the remote server

Each message is limited to 512 bytes of text.

The VERBOSE property is useful for looking at the contents of the HTTP or FTP messages being sent to and from the remote HTTP or FTP server. See [“Using Callbacks with the IDLnetURL Object”](#) on page 5343 for additional details.

By default, the VERBOSE property is set to 0 (false).

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLnetURL::Cleanup

The IDLnetURL::Cleanup procedure method performs all cleanup operations on the object, and closes all open connections when the object is destroyed.

Note

Cleanup methods are special *lifecycle* methods, and as such cannot be called outside the context of object creation and destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLnetURL::]Cleanup (*In a lifecycle method only.*)

Return Value

None.

Arguments

None.

Keywords

None.

Version History

6.4	Introduced
-----	------------

IDLnetURL::CloseConnections

The IDLnetURL::CloseConnections function method closes all the existing connections to remote HTTP and FTP servers. Closing a connection using this method is useful when it is necessary to change a login, enable or disable SSL, or start a new set of transactions on the FTP or HTTP server. In high-security environments it can be useful to immediately close a connection after the transaction is completed.

This object will cache up to five existing connections to remote HTTP or FTP servers. Once a connection is established to a remote server, the connection will be reused on subsequent transactions with the remote server. Reusing a connection can save time because the connect, login, and SSL handshake information does not need to be repeated.

Note

Typically, a remote server will close an existing connection after a period of inactivity. When this occurs, the closed connection is removed from the existing connections list.

Syntax

Obj->[IDLnetURL::](#)CloseConnections

Return Value

None.

Arguments

None.

Keywords

None.

Version History

6.4	Introduced
-----	------------

IDLnetURL::FtpCommand

The IDLnetURL::FtpCommand function method can be used to execute FTP commands, delete files, make directories, delete directories, and change directories on the remote FTP server.

This method throws an error if the call fails. Use a catch statement to trap errors and print the error messages and response codes.

Note

When the FTP server issues response code 530 or 67, a login is required or the current username and password are incorrect.

This method sets the RESPONSE_CODE property, which contains the last FTP status code received. The RESPONSE_HEADER and RESPONSE_CODE properties are useful for troubleshooting problems. Receiving callbacks and printing the status strings with the VERBOSE property set to 1 is another valuable troubleshooting technique. Refer to [“Using Callbacks with the IDLnetURL Object”](#) on page 5343 for details.

If a FTP connection fails, it may be necessary to switch the connection mode from active to passive using the FTP_CONNECTION_MODE property.

Syntax

```
Result = Obj->[IDLnetURL::]FtpCommand(command [, /FTP_EXPLICIT_SSL]  
[, URL=string])
```

Return Value

The return value is the response header, which is a string. Examine the response header to determine if the command succeeded or failed.

Arguments

Command

A string or string array containing FTP commands to execute.

The following table lists the FTP commands that IDL allows:

CWD	Change a directory
DELE	Delete a file
MKD	Make a directory
RMD	Remove a directory
RNFR	Rename from
RNTO	Rename to Note - To rename a file, you must issue both the RNFR and RNTO commands in succession (see the following examples)

The following are examples of using standard commands:

```
"CWD data"
"CWD .."

"DELE path/filename"
"DELE /path/filename"

"MKD /path"
"MKD path"

"RMD /path"
"RMD path"

"RNFR /path/existingfilename"
"RNTO /path/newfilename"
...or...
"RNFR path/existingfilename"
"RNTO path/newfilename"
```

Keywords

FTP_EXPLICIT_SSL

Set this keyword to explicitly use SSL to transfer the commands and data to or from the remote FTP server. It is not necessary to set this keyword when the scheme is “ftps”, as this implicitly activates SSL. See “[Secure FTP](#)” on page 5339 for additional notes on SSL connections.

URL

Set this keyword equal to the complete URL string of the location for which the command is to be executed. If this keyword is set, the `URL_*` properties are ignored.

Warning

If you include a username and password as plain text in a URL, both are potentially visible to others. To avoid this security risk, set the `URL_*` properties, including the `URL_USERNAME` and `URL_PASSWORD` properties, specifically.

Examples

The following example uses the `IDLnetURL::FtpCommand` function method to send a `cwd` FTP command to the ITT Visual Information Solutions FTP server. This command changes the working directory to `/doc/examples` (this is the only command that can be issued with this method to a read-only server).

Example Code

The code sample `url_docs_ftp_cmd.pro` is also located in the `examples/doc/objects` subdirectory of the IDL distribution. View the file in an IDL editor window by entering `.EDIT url_docs_ftp_cmd.pro` at the IDL Command Line.

```

;-----
FUNCTION URL_CALLBACK, status, progress, data

    ; print the info msgs from the url object
    PRINT, status

    ; return 1 to continue, return 0 to cancel
    RETURN, 1
END

;-----
PRO url_docs_ftp_cmd

    ; Catch any errors generated by the IDLnetURL object
    CATCH, errorStatus
    IF (errorStatus NE 0) THEN BEGIN
        CATCH, /CANCEL

        ; Display the error msg in a dialog and at the IDL
        ; command line.
        r = DIALOG_MESSAGE(!ERROR_STATE.msg, TITLE='URL Error', $
            /ERROR)

```

```

PRINT, !ERROR_STATE.msg

; Get the properties that tell us more about
; the error and display at the IDL command line.
ourl->GetProperty, RESPONSE_CODE=rspCode, $
    RESPONSE_HEADER=rspHdr, RESPONSE_FILENAME=rspFn
PRINT, 'rspCode = ', rspCode
PRINT, 'rspHdr= ', rspHdr
PRINT, 'rspFn= ', rspFn

; Destroy the url object and return.
OBJ_DESTROY, ourl
RETURN
ENDIF

; Create a new url object
ourl = OBJ_NEW('IDLnetUrl')

; Specify the callback function
ourl->SetProperty, CALLBACK_FUNCTION = 'URL_CALLBACK'

; Set verbose to 1 to see more details
ourl->SetProperty, VERBOSE = 1

; Specify that we will do an ftp transaction
ourl->SetProperty, URL_SCHEME = 'ftp'

; The ITT Visual Information Solutions FTP server
ourl->SetProperty, URL_HOST = 'data.ittvis.com'

; Build an array of commands. The following sample command
; array changes to the /doc/examples dir (which is all
; that can be done with this method on a read-only server.
; The following command will always work:
; cmds = 'cwd /'

cmds = ['cwd doc/examples']

; Specify the appropriate username and password. If the
; username is 'Anonymous', use a null string for the password.
ourl->SetProperty, URL_USERNAME = 'Anonymous'
ourl->SetProperty, URL_PASSWORD = ''

; Send the command array to the FTP server, saving the
; responses in an IDL variable.
respHdr = ourl->FtpCommand(cmds)

; Display the responses.

```

```
PRINT, 'response header for the ftp commands'  
PRINT, respHdr  
  
; Destroy the url object  
OBJ_DESTROY, ourl
```

END

-----	------------

IDLnetURL::Get

The IDLnetURL::Get function method retrieves a resource from a remote HTTP or FTP server and writes it to disk, a memory buffer, or an array of strings. The returned data is written to disk in the location specified by the FILENAME keyword. If the file name is the same between method calls, the last file received is overwritten.

When retrieving a file from a remote FTP server, the Get method automatically changes directories to the path specified on the server before retrieving the file. The path is specified in the URL keyword or in the URL_PATH property.

This method supports SSL data transfers to and from remote HTTP or FTP servers. When the scheme is FTP and the path ends in a slash, a directory listing for the path-specified directory is returned. If the scheme is HTTP and the path is not set, this method attempts to get the `index.htm` file from the remote HTTP server.

This method sets the [RESPONSE_CODE](#) and [RESPONSE_HEADER](#) properties, which contain response information sent by the remote server. The information stored in these properties can be useful when troubleshooting transmission problems. Receiving callbacks and printing the status strings with the [VERBOSE](#) and [CALLBACK_FUNCTION](#) properties set is another valuable troubleshooting technique.

This method generates an error if the transmission fails. Use a CATCH statement to trap errors and print the error messages and response codes.

Note

When the HTTP server issues response code 401 or the FTP server generates response code 530, a login is required or the current username and password are incorrect.

Calls to the Get method are canceled when the return value of the callback function is zero. See [“Using Callbacks with the IDLnetURL Object”](#) on page 5343 for details.

If a FTP connection fails, try switching the connection mode from Active to Passive using the FTP_CONNECTION_MODE property.

Syntax

```
Result = Obj->[IDLnetURL::]Get( [, BUFFER=value] [, FILENAME=string]
    [, /FTP_EXPLICIT_SSL] [, /STRING_ARRAY] [, URL=string])
```

Return Value

This method returns one of the following:

- A string containing the full path of the file retrieved from the remote HTTP or FTP server.
- A byte vector, if the `BUFFER` keyword is set.
- An array of strings, if the `STRING_ARRAY` keyword is set.
- A null string, if no data were returned by the method.

Arguments

None.

Keywords

FILENAME

Set this keyword equal to a string that holds the file name and path where the retrieved file is locally stored.

- If `FILENAME` specifies a full path, the file is stored in the specified path.
- If `FILENAME` specifies a relative path, the path is relative to IDL's current working directory.
- If `FILENAME` is not present or specifies a null string, the file is stored in IDL's current working directory under the name `idl.dat`.
- If `FILENAME` is the same between calls to `Get`, the last file received is overwritten.

BUFFER

If this keyword is set, the return value is a buffer and the `FILENAME` keyword is ignored.

FTP_EXPLICIT_SSL

Set this keyword to explicitly use SSL to transfer commands and data to or from a remote FTP server. It is not necessary to set this keyword when the scheme is "ftps" (which implicitly activates SSL). See "[Secure FTP](#)" on page 5339 for additional notes on SSL connections.

STRING_ARRAY

Set this keyword to treat the return value as an array of strings. If this keyword is set, the FILENAME and BUFFER keywords are ignored.

URL

Set this keyword equal to a string that specifies the complete URL of the resource to be retrieved. The specified URL must contain a scheme and host, and may contain an optional path. If this keyword is set, the URL_* properties are ignored. If this keyword is not set, the URL_HOST property must be set prior to calling this method.

Note

When using a URL that contains a password, the password appears as clear text. To avoid this security problem when using a password, set the URL_* properties explicitly rather than using the URL keyword.

Examples

The following example uses the IDLnetURL::Get function method to retrieve files from the /doc/examples/ directory of the ITT Visual Information Solutions FTP server. A binary image file is saved to your local IDL main directory, and a text file is retrieved as an array of strings.

Example Code

The code sample `url_docs_ftp_get.pro` is also located in the `examples/doc/objects` subdirectory of the IDL distribution. View the file in an IDL editor window by entering `.EDIT url_docs_ftp_get.pro` at the IDL Command Line.

```

;-----
FUNCTION Url_Callback, status, progress, data

    ; print the info msgs from the url object
    PRINT, status

    ; return 1 to continue, return 0 to cancel
    RETURN, 1
END

;-----
PRO url_docs_ftp_get

    ; If the url object throws an error it will be caught here

```

```

CATCH, errorStatus
IF (errorStatus NE 0) THEN BEGIN
    CATCH, /CANCEL

    ; Display the error msg in a dialog and in the IDL output log
    r = DIALOG_MESSAGE(!ERROR_STATE.msg, TITLE='URL Error', $
        /ERROR)
    PRINT, !ERROR_STATE.msg

    ; Get the properties that will tell us more about the error.
    oUrl->GetProperty, RESPONSE_CODE=rspCode, $
        RESPONSE_HEADER=rspHdr, RESPONSE_FILENAME=rspFn
    PRINT, 'rspCode = ', rspCode
    PRINT, 'rspHdr= ', rspHdr
    PRINT, 'rspFn= ', rspFn

    ; Destroy the url object
    OBJ_DESTROY, oUrl
    RETURN
ENDIF

; create a new IDLnetURL object
oUrl = OBJ_NEW('IDLnetUrl')

; Specify the callback function
oUrl->SetProperty, CALLBACK_FUNCTION = 'Url_Callback'

; Set verbose to 1 to see more info on the transaction
oUrl->SetProperty, VERBOSE = 1

; Set the transfer protocol as ftp
oUrl->SetProperty, url_scheme = 'ftp'

; The ITT VIS FTP server
oUrl->SetProperty, URL_HOST = 'data.ittvis.com'

; The FTP server path of the file to download
oUrl->SetProperty, URL_PATH = 'doc/examples/Day.jpg'

; Make a request to the ITT VIS FTP server.
; Retrieve a binary image file and write it
; to the local disk's IDL main directory.

fn = oUrl->Get(FILENAME = !DIR + '/Day.jpg' )

; Print the path to the file retrieved from the remote server
PRINT, 'filename returned = ', fn

; The FTP server path of the next file to download

```

```
oUrl->SetProperty, URL_PATH = 'doc/examples/ascii.txt'  
  
; Retrieve an ascii text file as an array of strings  
strings = oUrl->Get( /STRING_ARRAY )  
  
; Print the returned array of strings  
PRINT, 'array of strings returned:'  
for i=0, n_elements(strings)-1 do print, strings[i]  
  
; Destroy the url object  
OBJ_DESTROY, oUrl
```

END

Version History

6.4	Introduced
-----	------------

IDLnetURL::GetFtpDirList

The `IDLnetURL::GetFtpDirList` function method retrieves a list of files (returned as an array of strings) available from a remote FTP server on a particular path. The path must resolve to a directory and end with a slash. If the directory is empty, a single null string is returned. When the **SHORT** keyword is set, the FTP server may or may not include directories and file statistics in the returned listing.

This method sets the **RESPONSE_CODE** and **RESPONSE_HEADER** properties, which contain response information sent by the remote server. The information stored in these properties can be useful when troubleshooting transmission problems. Receiving callbacks and printing the status strings with the **VERBOSE** and **CALLBACK_FUNCTION** properties set is another valuable troubleshooting technique.

This method generates an error if the transmission fails. Use a **CATCH** statement to trap errors and print the error messages and response codes.

Note

If the FTP server generates response code 530 or 67, a login is required or the current username and password are incorrect. A catch statement can be used to trap errors and print the error messages and response codes.

If a FTP connection fails, try switching the connection mode from Active to Passive using the **FTP_CONNECTION_MODE** property.

Syntax

```
Result = Obj->[IDLnetURL:]GetFtpDirList( [, /FTP_EXPLICIT_SSL]  
    [, URL=string] [, /SHORT] )
```

Return Value

A string array containing the directory listing. If the directory is empty, the return value is a single null string.

Arguments

None.

Keywords

FTP_EXPLICIT_SSL

Set this keyword to explicitly use SSL to transfer commands and data to or from the remote FTP server. It is not necessary to set this keyword when the scheme is “ftps”, (which implicitly activates SSL). See “[Secure FTP](#)” on page 5339 for additional notes on SSL connections.

URL

Set this keyword equal to a string that specifies the complete URL of the location from which the directory listing is to be retrieved. If this keyword is set, the URL_* properties are ignored.

Note

When using a URL that contains a password, the password appears as clear text. To avoid this security problem when using a password, set the URL_* properties explicitly rather than using the URL keyword.

SHORT

Set this keyword to retrieve an abbreviated directory listing that does not include file statistics. FTP servers do not implement the short listing switch consistently; a server may or may not show directory entries and symbolic links correctly. If the SHORT keyword is not set, the default method behavior is to include file statistics in the directory listing, usually including file size and date.

Examples

The following example uses the IDLnetURL::GetFtpDirList function method to retrieve the listing from the /doc/examples/ directory of the ITT Visual Information Solutions FTP server.

Example Code

The code sample url_docs_ftp_dir.pro is also located in the examples/doc/objects subdirectory of the IDL distribution. View the file in an IDL editor window by entering .EDIT url_docs_ftp_dir.pro at the IDL Command Line.

```

;-----
FUNCTION Url_Callback, status, progress, data

```

```

; print the info msgs from the url object
PRINT, status

; return 1 to continue, return 0 to cancel
RETURN, 1
END

;-----
PRO url_docs_ftp_dir

; if the url object throws an error it will be caught here
CATCH, errorStatus
IF (errorStatus NE 0) THEN BEGIN
    CATCH, /CANCEL

    ; display the error msg in a dialog
    r = DIALOG_MESSAGE(!ERROR_STATE.msg, TITLE='URL Error', $
        /ERROR)
    PRINT, !ERROR_STATE.msg

    ; get the properties that will tell us more detail about $
    ; the error.
    oUrl->GetProperty, RESPONSE_CODE=rspCode, $
        RESPONSE_HEADER=rspHdr, RESPONSE_FILENAME=rspFn
    PRINT, 'rspCode = ', rspCode
    PRINT, 'rspHdr= ', rspHdr
    PRINT, 'rspFn= ', rspFn

    ; since we are done we can destroy the url object
    OBJ_DESTROY, oUrl
    RETURN
ENDIF

; create a new url object
oUrl = OBJ_NEW('IDLnetUrl')

; the url object will make callbacks to this pro code function
oUrl->SetProperty, CALLBACK_FUNCTION = 'Url_Callback'

; set VERBOSE to 1 to see more info on the transaction
oUrl->SetProperty, VERBOSE = 1

; an ftp transaction
oUrl->SetProperty, URL_SCHEME = 'ftp'

; The ITT VIS FTP server
oUrl->SetProperty, URL_HOST = 'data.ittvis.com'

```

```
; name of dir to get directory listing for on the $
; remote ftp server
oUrl->SetProperty, URL_PATH = 'doc/examples/'

; the appropriate username and password
oUrl->SetProperty, URL_USERNAME = 'Anonymous'
oUrl->SetProperty, URL_PASSWORD = ''

; Get the directory listing
dirList = oUrl->GetFtpDirList()

PRINT, ' directory listing: '
PRINT, dirList, FORMAT='(A)'

; we are done so we release the url object
OBJ_DESTROY, oUrl
END
```

-----	------------

IDLnetURL::GetProperty

The IDLnetURL::GetProperty procedure method retrieves the value of a property for the IDLnetURL object.

Syntax

Obj->[IDLnetURL::]GetProperty [, PROPERTY = *value*]

Return Value

None.

Arguments

None.

Keywords

Any property listed under [IDLnetURL Properties](#) that contains the word “Yes” in the “Get” row of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.4	Introduced
-----	------------

IDLnetURL::Init

The IDLnetURL::Init function method initializes an IDLnetURL object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
obj =OBJ_NEW('IDLnetURL')
```

or

```
Obj->[IDLnetURL::]Init (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object. When called directly within a subclass Init method, the return value is 1 if initialization is successful, and zero if not.

Arguments

None.

Keywords

Any property listed under [IDLnetURL Properties](#) that contains the word “Yes” in the “Init” row of the Properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword and set it equal to the appropriate property value.

Version History

6.4	Introduced
-----	------------

IDLnetURL::Put

The IDLnetURL::Put method sends a file or a buffer of data to a remote HTTP or FTP server.

This method returns when one of the following events occurs:

- The method completes successfully.
- The method encounters an HTTP or FTP error.
- The return status of the callback function indicates the caller wants to cancel the Put.

If the URL keyword is not set, the URL_PATH property must be set to the destination (filename) on the remote HTTP or FTP server.

When sending data to an HTTP server, IDL uses the “Put” transmission method by default. To use the “Post” transmission method, set the POST keyword.

When sending a file to a remote FTP server, the Put method automatically changes directories to the path specified before sending the desired file. If the directories do not exist before sending the desired file, the Put method attempts to create them using the path specified.

Calls to the Put method are canceled when the return value of the callback function is zero. See “Using Callbacks with the IDLnetURL Object” on page 5343 for details.

Errors

This method generates an error if the transmission fails, or if the remote server is unable to complete the Put or Post request. When an error is generated, the remote HTTP server typically sends an HTML response file indicating the reason for the failure. The `RESPONSE_FILENAME` property contains the complete path to the error file.

This method sets the `RESPONSE_CODE` and `RESPONSE_HEADER` properties, which contain response information sent by the remote server. The information stored in these properties can be useful when troubleshooting transmission problems. Receiving callbacks and printing the status strings with the `VERBOSE` and `CALLBACK_FUNCTION` properties set is another valuable troubleshooting technique.

Use a CATCH statement to trap errors and print the error message and response code. A HTTP server 401 response code, or a FTP server 530 or 67 response code means that a login is required, or the current username and password are incorrect.

If a FTP connection fails, you may need to switch the connection mode from Active to Passive using the `FTP_CONNECTION_MODE` property.

A HTTP Put or HTTP Post will fail if the remote HTTP server is out of space, or if the path (destination of the file or data) does not exist or can not be created.

Remote servers typically must be configured to support HTTP Put or Post operations. If the remote server does not support these operations, the HTTP Put or Post will fail. Typical error responses to this situation are “400 Bad Request” and “405 Method Not Allowed”.

Syntax

```
Result = Obj->[IDLnetURL::] Put ( data,
    [, BUFFER=value][, /FTP_EXPLICIT_SSL] [, /POST] [, URL=string])
```

Return Value

If the server sent a response to the Put or Post request, the return value contains the complete path to the response file. If the server did not send a response to the Put or Post request, the return value is a null string.

Arguments

DATA

When the `BUFFER` keyword is not set, the data argument is a string containing the name of a file to be transferred. In this case:

- If *Data* specifies a full path, the file is uploaded from the specified path.
- If *Data* specifies a relative path, the path is relative to IDL's current working directory.

When the `BUFFER` keyword is set, *Data* is an IDL variable containing the data to be transferred. The data buffer can be a scalar or an array of the following types:

- `BYTE`
- `INT`
- `UINT`
- `LONG`
- `ULONG`
- `LONG64`
- `ULONG64`
- `FLOAT`
- `DOUBLE`
- `STRING`

Note

If the buffer contains string values, a linefeed character (10B) is appended to the end of each string before it is passed to the remote server.

Keywords

BUFFER

Set this keyword to cause the *Data* argument to be interpreted as the name of an IDL variable to be sent to the remote server.

FTP_EXPLICIT_SSL

Set this keyword to explicitly use SSL to transfer the commands and data to or from the remote FTP server. It is not necessary to set this keyword when the scheme is “ftps” (which implicitly activates SSL). See “[Secure FTP](#)” on page 5339 for additional notes on SSL connections.

POST

Set this keyword to use the HTTP POST command rather than the HTTP PUT command. This keyword is ignored if the URL Scheme is 'ftp' or 'ftps'.

URL

Set this keyword equal to a string that specifies the complete URL of the location to which the data will be transferred. If this keyword is set, the URL_* properties are ignored.

Note

When using a URL that contains a password, the password appears as clear text. To avoid this security problem when using a password, set the URL_* properties explicitly rather than using the URL keyword.

Examples

Conceptual Examples

```
result = Obj->Put(file)
```

The input parameter is a full or relative path to the local file to transfer to the remote server. The URL_* properties are used. The URL_HOST and URL_PATH properties must be set prior to making this type of Put call. The URL_PATH property determines the destination (filename) on the remote server. The URL_SCHEME property determines if the file is sent using HTTP or FTP. If the remote server sends a response file, it is written to the location specified by the RESPONSE_FILENAME property.

```
result = Obj->Put(file, URL='scheme://host/path')
```

The input parameter is a full or relative path to the local file to transfer to the remote server. The URL_* properties are not used. The destination and filename used on the remote server is determined by the path portion of the URL keyword.

```
result = Obj->Put(data, /BUFFER, /POST)
```

The input parameter is an IDL variable containing the data to post to the remote server. The `URL_*` properties are used. The `URL_HOST` and `URL_PATH` properties must be set prior to making this type of Post call. The `URL_PATH` property determines the destination (typically a CGI script that processes the posted data) on the remote server. In this case, the `URL_SCHEME` property must be HTTP.

Extended Example

```

;-----
FUNCTION Url_Callback, status, progress, data

    ; Print the info msgs from the url object
    PRINT, status

    ; Return 1 to continue, return 0 to cancel
    RETURN, 1
END

;-----
PRO Url_Docs_Ftp_Put

    ; If the IDLnetURL object throws an error it will be caught here
    CATCH, errorStatus
    IF (errorStatus NE 0) THEN BEGIN
        CATCH, /CANCEL

        ; Display the error msg in a dialog and in the IDL Output log
        r = DIALOG_MESSAGE(!ERROR_STATE.msg, TITLE='URL Error', $
            /ERROR)
        PRINT, !ERROR_STATE.msg

        ; Get the properties that will tell about the error.
        oUrl->GetProperty, RESPONSE_CODE=rspCode, $
            RESPONSE_HEADER=rspHdr, RESPONSE_FILENAME=rspFn
        PRINT, 'rspCode = ', rspCode
        PRINT, 'rspHdr= ', rspHdr
        PRINT, 'rspFn= ', rspFn

        ; Since we are done we can destroy the url object
        OBJ_DESTROY, oUrl
        RETURN
    ENDIF

    ; Sreate a new url object
    oUrl = OBJ_NEW('IDLnetUrl')

    ; Specify the callback function

```

```

oUrl->SetProperty, CALLBACK_FUNCTION = 'Url_Callback'

; Set verbose to 1 to see more info on the transaction
oUrl->SetProperty, VERBOSE = 0

; This is an ftp transaction
oUrl->SetProperty, URL_SCHEME = 'ftp'

; EDIT THIS LINE: put in a valid ftp server name
oUrl->SetProperty, URL_HOST = 'ftp_server_name'

; Specify the destination path/filename
; EDIT THIS LINE: put in the valid path for your server
oUrl->SetProperty, URL_PATH = 'valid_path/Night.jpg'

; Specify the appropriate username and password
oUrl->SetProperty, URL_USERNAME = 'Anonymous'
oUrl->SetProperty, URL_PASSWORD = ''

; Build a path to an IDL example jpeg file
fn = FILEPATH('Night.jpg',SUBDIR=['examples', 'data'])

; Use an ftp put request to send the file to the $
; remote ftp server
result = oUrl->Put(fn)

; we are done so we release the url object
OBJ_DESTROY, oUrl
END

```

Chapter 34

Miscellaneous Object Classes

This chapter describes IDL's Container, Bridge, Savefile, COM, Java, and Trackball class libraries.

IDL_Container	5398	IDLcomIDispatch	5466
IDL_IDLBridge	5410	IDLjavaObject	5473
IDL_Savefile	5440	IDLsysMonitorInfo	5482
IDLcomActiveX	5463	TrackBall	5500

IDL_Container

An IDL_Container object holds other objects. The IDL_Container class, provides a way to group disparate IDL objects into single object, and allows you to easily move or destroy the objects within the container. Destroying an IDL_Container object destroys any objects that have been added to the container via the Add method.

Superclasses

None

Creation

See “[IDL_Container::Init](#)” on page 5406.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDL_Container::Add](#)
- [IDL_Container::Cleanup](#)
- [IDL_Container::Count](#)
- [IDL_Container::Get](#)
- [IDL_Container::Init](#)
- [IDL_Container::IsContained](#)
- [IDL_Container::Move](#)
- [IDL_Container::Remove](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
-----	------------

IDL_Container Properties

Objects of this class have no properties of their own.

IDL_Container::Add

The IDL_Container::Add procedure method adds one or more child objects to the container.

Syntax

Obj->[IDL_Container::]Add, *Objects* [POSITION=*index*]

Arguments

Objects

An object instance or array of object instances to be added to the container object.

Keywords

POSITION

Set this keyword equal to a scalar or array of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within the container at which a new object should be placed. The default is to add new objects at the end of the list of contained items.

Examples

If the container has three objects, a new object will be placed at the fourth position. Since positions begin at zero, this would be equivalent to setting POSITION=3.

Version History

5.0	Introduced
-----	------------

IDL_Container::Cleanup

The IDL_Container::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDL_Container::]Cleanup (In a lifecycle method only.)

Arguments

None.

Keywords

None.

Version History

5.0	Introduced
-----	------------

IDL_Container::Count

The IDL_Container::Count function method returns the number of objects contained by the container object.

Syntax

Result = *Obj*->[IDL_Container::]Count()

Arguments

None.

Keywords

None.

Version History

5.0	Introduced
-----	------------

IDL_Container::Get

The IDL_Container::Get function method returns an array of object references to objects in a container. Unless the ALL or POSITION keywords are specified, the first object in the container is returned. If no objects are found in the container, the Get function returns -1.

Syntax

```
Result = Obj->[IDL_Container::]Get ([, /ALL [, ISA=class_name(s)] | ,  
    POSITION=index] [COUNT=variable] )
```

Arguments

None.

Keywords

ALL

Set this keyword to return an array of object references to all of the objects in the container.

COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function. If the ALL keyword is also specified, specifying this keyword is the same as calling the IDL_Container::Count method.

ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

Note

This keyword is ignored if the ALL keyword is not provided.

POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

Version History

5.0	Introduced
-----	------------

IDL_Container::Init

The IDL_Container::Init function method initializes the container object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDL_Container')
```

or

```
Result = Obj->[IDL_Container::]Init() (In a lifecycle method only.)
```

Arguments

None.

Keywords

None.

Version History

5.0	Introduced
-----	------------

IDL_Container::IsContained

The IDL_Container::IsContained function method returns true (1) if the specified object is in the container, or false (0) otherwise.

Syntax

Result = *Obj*->[IDL_Container::]IsContained(*Object* [, POSITION=*variable*])

Arguments

Object

The object reference or vector of object references of the object(s) to search for in the container.

Keywords

POSITION

Set this keyword to a named variable that upon return will contain the position(s) at which (each of) the argument(s) is located within the container, or -1 if it is not contained.

Version History

5.0	Introduced
-----	------------

IDL_Container::Move

The `IDL_Container::Move` procedure method moves an object from one position in a container to a new position. The order of the other objects in the container remains unchanged.

Positioning within a container controls the rendering order of the contained objects. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later. Objects located “behind” other objects in three-dimensional space must be rendered before objects in front of them, even if the “front” objects are translucent.

Syntax

Obj->[IDL_Container::]Move, Source, Destination

Arguments

Source

The zero-based index of the current location of the object to be moved.

Destination

The zero-based index of the location in the container where the object will reside after being moved.

Keywords

None.

Version History

5.0	Introduced
-----	------------

IDL_Container::Remove

The IDL_Container::Remove procedure method removes an object from the container.

Syntax

```
Obj->[IDL_Container::]Remove [, Child_object] [, POSITION=index] [, /ALL]
```

Arguments

Child_object

An object reference or array of object references for the objects to be removed from the container. If *Child_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the container will be removed.

Keywords

ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Child_object* argument is not required.

POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child_object* argument is supplied, this keyword is ignored.

Version History

5.0	Introduced
-----	------------

IDL_IDLBridge

The IDL_IDLBridge object class allows an IDL session to create and control other IDL sessions, each of which runs as a separate process. Each instantiation of an IDL_IDLBridge object corresponds to one such *child* process. Child processes are controlled by the *parent IDL process* - the IDL process that created the IDL_IDLBridge objects. IDL_IDLBridge objects support the following operations:

- Exchanging data between the parent IDL process and the child process by copying IDL variables between them using the SetVar and GetVar methods.
- Executing arbitrary IDL commands in the child process. In synchronous operation, the parent IDL session waits for the child to complete the specified task before continuing. In asynchronous operation, the parent IDL session does not wait, and the two processes run in parallel.
- Querying the current status of the child process while it asynchronously executes an IDL command.
- Registering a callback that is called when an asynchronous command finishes execution.
- Aborting a currently running asynchronous command in a child process.

Using these facilities, one or more IDL_IDLBridge child processes can be used to perform work in parallel with each other and with the parent IDL process that starts them.

It is important to realize that IDL_IDLBridge child processes do not inherit any state information from the parent IDL process. This means that the child process will not have access to data, compiled routines, system variables, or even the current working directory of the parent process.

Warning

On UNIX systems, the IDL_IDLBridge requires that the DISPLAY environment variable be set to a valid X Windows display. If no display is available, execution of the IDL_IDLBridge will halt, with error messages that include:

```
'IDL_IDLBridge: Unable to establish X Connection.'
```

Note

An IDL_IDLBridge object child process is designed to perform computationally intensive, background processing tasks while you continue working with the main

IDL program. It is not designed to provide asynchronous interaction with interactive user interfaces.

Note

A startup file is *not* automatically executed when a child process is created. To manually run a startup file, see [“Executing a Batch File in a Child Process”](#) on page 5426. Also see [“Understanding When Startup Files are Not Executed”](#) (Chapter 1, *Using IDL*) for more details.

Note

The `Execute`, `GetVar`, and `SetVar` methods to the `IDL_IDLBridge` object are disabled in IDL Virtual Machine mode. As a result, while it is possible to create an `IDL_IDLBridge` object in code that runs in the IDL Virtual Machine, it is not particularly useful.

Superclasses

None

Creation

See [IDL_IDLBridge::Init](#).

Properties

Objects of this class have the following properties. See [“IDL_IDLBridge Properties”](#) on page 5418 for details on individual properties.

- [CALLBACK](#)
- [OUTPUT](#)
- [USERDATA](#)

Methods

This class has the following methods:

- [IDL_IDLBridge::Abort](#)
- [IDL_IDLBridge::Cleanup](#)
- [IDL_IDLBridge::Execute](#)

- [IDL_IDLBridge::GetProperty](#)
- [IDL_IDLBridge::GetVar](#)
- [IDL_IDLBridge::Init](#)
- [IDL_IDLBridge::OnCallback](#)
- [IDL_IDLBridge::SetProperty](#)
- [IDL_IDLBridge::SetVar](#)
- [IDL_IDLBridge::Status](#)

Examples

The following sections provide several examples of creating and using IDL_IDLBridge objects:

- [“Multiple Child Processes Example”](#) on page 5413 — a demo program that allows you to create and interact with multiple child processes.
- [“Tiling and Child Image Processing Example”](#) on page 5414 — an image tiling application that includes the ability to filter a very large image in a child process, and display the filtered image once processing is complete.
- [“Child Processing Distillation Example”](#) on page 5415 — a simple widget interface that exposes the child processing functionality found in the tiling application.

About Debugging Child Processes

Debugging a routine running in a child IDL process presents challenges not present when debugging routines running in the main IDL process. Child IDL processes have no direct connection to the parent IDL process. Because of this lack of connection, the following conditions exist:

- The IDL Workbench's debugging tools are not available
- Breakpoints are not honored
- Output from PRINT statements will not appear in the output log

To work around these issues, develop and debug routines in an interactive IDL process before running them in a child process. Once you are ready to test your routines in a child process, consider using one or more of the following approaches:

- Consider writing status and error information generated by the routines in the child process to a text file. This can be easily accomplished by setting the **OUTPUT** property.
- Display debugging output using `DIALOG_MESSAGE` rather than `PRINT`
- Use the `IDL_IDLBridge::Status` method to check for completion status of the entire routine

Note

For information on how to return `HELP` information for a child process, see the Examples section of “[IDL_IDLBridge::GetVar](#)” on page 5429.

Note

On Windows, you can see debug output generated by the `IDL_BRIDGE_DEBUG` environment variable in the Debug Monitor (`DBMON.exe`), available with the Windows Platform SDK. Use the `IDL_BRIDGE_DEBUG` environment variable setting to control the level of debug output detail. See “[IDL_BRIDGE_DEBUG](#)” (Chapter 1, *Using IDL*) for more information.

Multiple Child Processes Example

This example lets you create and interact with a number of child processes where each process executes an IDL command asynchronously. This means that multiple IDL child processes can be completing tasks while the main IDL process remains active. This demonstration of the `IDL_IDLBridge` functionality can be used as a guide when using the `IDL_IDLBridge` object in your own code.

Tip

You can also investigate the effect of executing commands synchronously by commenting out the `NOWAIT` keyword in the `Execute` method call.

Example Code

This example `idlbridge_demo.pro`, is located in the `examples/doc/bridges` subdirectory of the IDL distribution. Run the example procedure by entering `idlbridge_demo` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT idlbridge_demo.pro`.

Run the program and click **Execute** to launch an asynchronous child process that plots a surface in another window. Create additional `IDL_IDLBridge` objects by selecting **File** → **New**. Since these processes execute commands asynchronously, you can start and abort one or more processes at will, all while continuing to interact with the main IDL process.

Note that once a process is initiated, the **Execute** button is desensitized. If it were not desensitized and you clicked **Execute** a second time (while the initial request was still being processed), execution would halt with the error, “The object’s associated IDL process is currently busy.” All child processes must finish executing one command before the next command is accepted. However, you can continue to interact with the parent process or other child processes while a child process executes a command asynchronously.

Note

You can also check status before calling the `Execute` method as described in “[Avoiding Busy Execution Errors](#)” on page 5426.

Note

A second version of this example, `idlbridge_demo_object.pro`, provides the same functionality without the use of a callback procedure. This requires using *timer events* to continuously check the `IDL_IDLBridge::Status` method results. See “[Timer Events](#)” (Chapter 3, *User Interface Programming*) for more information on widget timers.

Tiling and Child Image Processing Example

This example is an extension of the tiling application example described in “[Example: JPEG2000 Files for Tiling](#)” (Chapter 4, *Object Programming*). This example displays a very large file (over 15 MB) and lets you explore the tiled image, zooming in or out and panning. It also includes a child process that applies the Roberts edge detection filter to the image data and creates a new 22 MB file. Since the filtering process occurs asynchronously in a child process, the tiling application can continue responding to requests for tile data and display the required tiles.

Example Code

This example, `idlbridge_tilingjpg2_doc.pro`, is located in the `examples/doc/bridges` subdirectory of the IDL distribution and calls `idlbridge_img_processing.pro`. Run the example procedure by entering `idlbridge_tilingjpg2` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT idlbridge_tilingjpg2.pro`.

In this example, the `Execute` method of the `IDL_IDLBridge` object is passed a string that contains:

- The name of a procedure (`idlbridge_img_processing.pro`), which contains the image filtering code
- The JP2 filename, which is a procedure argument

The following lines transfer the variable value using `SetVar` and launch the `idlbridge_img_processing.pro` procedure in a child process (`oBridge`). The command is executed asynchronously due to the `NOWAIT` keyword.

```
oBridge->SetVar, 'filename', (*pState).jp2filename
oBridge->Execute, $
'idlbridge_img_processing, filename', /NOWAIT
```

When you run the tiling application (`idlbridge_tilingjp2_doc.pro`), click the **Process Image** button to begin filtering the data in the child process. When processing is complete, the filtered image is automatically displayed.

Note

This example relies on an image filename to determine what is to be filtered. If the image data were interactively updated through actions such as command line processing, you could pass the actual image data instead of the filename. You may pass scalar or array variables of numeric or string type (those allowed by [IDL_IDLBridge::SetVar](#)) to a child process.

Child Processing Distillation Example

This simple widget application (`idlbridge_simple_doc.pro`) launches the `idlbridge_img_processing.pro` procedure in a child process just as the previous tiling application does, but provides streamlined code and a simplified interface so that it is easier to follow execution and status retrieval for the `IDL_IDLBridge` object. Run the example and click **Process Image** to launch `idlbridge_img_processing.pro` in a child process.

Example Code

This example, `idlbridge_simple_doc.pro`, is located in the `examples/doc/bridges` subdirectory of the IDL distribution and calls `idlbridge_img_processing.pro`. Run the example procedure by entering `idlbridge_img_processing` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT idlbridge_img_processing.pro`.

In this simplified example, it is easier to see how the progress bar (created in the child process) can be controlled from the parent IDL session. Typically, the progress bar base is destroyed when the image processing program finishes. However, if the user aborts the process or if an error halts execution, the end of the image processing program is never reached.

To kill the widget in the child process, you need the widget ID. You could create and update a widget ID variable in the child process, and then destroy the specific widget from a call in the parent process. However, this ties the two programs together. The parent program must know information that is internal to the child process.

Instead of requiring such a connection, you can use a common block. When you assign the value of the widget ID to a common block variable in the child process, you can access this value without having to pass it in from anywhere (either from the parent process or from the child process `pState` variable). This compartmentalizes processing. The parent process simply calls a routine in the child process to tell it that its operation was terminated abruptly by the master process and that it should clean up any state related to it. The child process routine accesses the progress bar widget ID from the common block and cleans up. In the specified programs, notice the following relevant lines:

```

; In idlbridge_simple_doc.pro, call the child process routine if
; the user aborts execution or if it ends due to an error.
(*pState).oIDLBridge->Execute, $
    'idlbridge_img_processing_abort_cleanup'

;...
; In idlbridge_img_processing.pro, access the TLB ID,
; wChildBase, which is stored in the common block and cleanup.
PRO idlbridge_img_processing_abort_cleanup

    COMMON shareWidID, wChildBase
    WIDGET_CONTROL, wChildBase, GET_UVALUE=pState
    WIDGET_CONTROL, wChildBase, /DESTROY
    PTR_FREE, pState
END

```

Image Processing Child Procedure

The image processing procedure (`idlbridge_img_processing.pro`), which is called from the tiling application and the simple widget interface, applies a Roberts filter to a given file. It also displays a progress bar to show the completion progress. While the `IDL_IDLBridge` object can return high level status (aborted, completed, halted with error, executing or idle) for a child process that is executing a command asynchronously, it does not give any indication of what percentage of a child process has been completed.

This image processing program updates the progress bar display throughout child process execution to provide more granular user feedback. Such a display could also provide feedback in a synchronous child process where status information is not available.

Example Code

This example, `idlbridge_img_processing.pro`, is located in the `examples/doc/bridges` subdirectory of the IDL distribution. Run the example procedure by entering `idlbridge_img_processing` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT idlbridge_img_processing.pro`. It is designed to be called from the previously mentioned tiling application or simple widget interface, but can be run independently once the required JP2 file has been created.

You can use a child process executing a command asynchronously much like a batch file—one that completes processing tasks without any interaction. In such cases, a user interface that relays progress isn't needed. However, if your application completes background processing that you care about, status updates are useful. This example shows one option for displaying such information if needed.

IDL_IDLBridge Properties

IDL_IDLBridge objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDL_IDLBridge::GetProperty](#). Properties with the word “Yes” in the “Init” column of the property table can be set via [IDL_IDLBridge::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDL_IDLBridge::SetProperty](#).

Note

For more information about the “Property Type”, “Name String”, and “Registered” columns, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties:

- [CALLBACK](#)
- [OUTPUT](#)
- [USERDATA](#)

CALLBACK

The name of a user-defined callback procedure that is automatically called when an asynchronous command is completed. When an asynchronous command is done (completed, aborted, or halted due to an error) the procedure specified by the `CALLBACK` property is called.

This callback procedure must have the following signature:

```
PRO BridgeCallbackName, Status, Error, Objref [, Userdata]
```

where each argument of the *BridgeCallbackName* procedure is given the following values:

- **Status** — an integer value that contains one of the following values:

Value	Description	ERROR Keyword Contents
2	Completed command	Null string
3	Error halted execution	Descriptive error string
4	Aborted execution	Abort message

Note

Because the Callback is only called when a command ends, values of Status=0 (Idle) or Status=1 (Executing) will never be returned. (See [IDL_IDLBridge::Status](#) for a list of all possible status values.)

- **Error** — a string corresponding to any error that may have occurred while executing the command in the child process. As shown in the table above, if *Status* contains an error status (3), the *Error* argument returns a descriptive error string. If *Status* indicates an aborted status (4), *Error* returns an abort message. Otherwise, the *Error* argument will be set to a null string.
- **Objref** — the object reference to the IDL_IDLBridge object that is associated with the callback.
- **Userdata** — the value of the [USERDATA](#) property. If the USERDATA property has been set, then this argument is required for your callback procedure. If the USERDATA property has not been set, this Userdata argument is optional, and if provided, will be set to an undefined variable.

When the asynchronous command is completed, aborted, or halted due to an error, the child IDL process calls back into the main IDL process. The main IDL process puts a callback event into the callback event queue for the bridge object. The callback queue for this bridge object is flushed (and the CALLBACK procedure or OnCallback method is called) when one of the following occurs:

- The widget event queue is flushed by IDL's widget event processing
- The user calls WIDGET_EVENT
- The user calls any IDL_IDLBridge method (except Abort)
- The user calls OBJ_DESTROY

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

Note

See the IDL_IDLBridge [“Examples”](#) on page 5412 for samples of setting the CALLBACK property. Also see the [“IDL_IDLBridge::OnCallback”](#) on page 5432.

OUTPUT

A string supplying the path and name of a file to which messages generated in the child process will be written. By default, any output written by the child process is quietly discarded by the IDL_IDLBridge object, and is not seen by the user. This is useful for debugged production quality code, but can be inconvenient when the code being executed by the child encounters errors, since you cannot see the text of the error messages.

Note

Under UNIX, but not Microsoft Windows, you may also set the OUTPUT keyword to a NULL file string (e.g. `OUTPUT= ' '`). In this case, the child process output is not diverted by the IDL_IDLBridge object, and is written by the operating system directly to stdout and stderr, which is usually the user's tty.

Property Type	String		
Name String	<i>not displayed</i>		
Get: Yes	Set: No	Init: Yes	Registered: No

USERDATA

A value of any type containing any information you wish. If USERDATA is set, the value contained within the USERDATA property is passed to the [CALLBACK](#) procedure after completion of an asynchronous command.

Note

Object references or pointers contained in the USERDATA property are not automatically cleaned up when the IDL_IDLBridge object is destroyed.

Property Type	Userdef		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDL_IDLBridge::Abort

The `IDL_IDLBridge::Abort` procedure method causes the asynchronous operation currently being executed by the child IDL process to abort, returning the child to the idle state. This operation is similar to what happens when a user of interactive IDL presses Ctrl-C. If the child process is not currently executing an asynchronous command, the call to `Abort` is quietly ignored and has no effect.

Calling `Abort` returns focus to the level of the calling IDL process, but does not perform any `IDL_IDLBridge` object cleanup or destruction. The corresponding child process remains responsive to requests for further processing.

Note

An actively executing process should always be aborted before the corresponding `IDL_IDLBridge` object is destroyed. See [IDL_IDLBridge::Cleanup](#) for details.

Syntax

`Obj->[IDL_IDLBridge::]Abort`

Arguments

None.

Keywords

None.

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::Cleanup

The `IDL_IDLBridge::Cleanup` procedure method performs all cleanup when the bridge object is destroyed.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

A program should ensure that a child process executing a command asynchronously has been completed or aborted before the associated `IDL_IDLBridge` object is destroyed. If you have started a process by calling the `IDL_IDLBridge::Execute` method with the `NOWAIT` keyword, you may want to wait for the process to become idle before destroying the bridge object.

When you call Cleanup, the following steps will occur:

- If there is a currently executing asynchronous command, then `IDL_IDLBridge::Abort` is called
- If there is a pending callback, then the `IDL_IDLBridge::OnCallback` method (and the `CALLBACK` procedure) is called
- The child IDL process is destroyed

Syntax

`OBJ_DESTROY, Obj`

or

`Obj->[IDL_IDLBridge::]Cleanup` (In a lifecycle method only.)

Arguments

None.

Keywords

None.

Examples

Ideally, a program should not destroy an IDL_IDLBridge object while an asynchronous command is busy. However, a cleanup method for child process that executes commands asynchronously should still include code to ensure an executing process is aborted or completed before it is destroyed.

For an IDL_IDLBridge object named oIDLBridge, use the following code to abort an executing process:

```
IF (oIDLBridge->Status() EQ 1) THEN oIDLBridge->Abort
OBJ_DESTROY, oIDLBridge
```

If you prefer to wait for the process to reach an idle state before destroying the bridge object, you can use code similar to the following:

```
WHILE (oIDLBridge->Status() NE 0) DO WAIT, 0.5
OBJ_DESTROY, oIDLBridge
```

Note

The `IDL_IDLBridge::Status` method returns status information for child processes executing commands asynchronously. A child process executing a command synchronously will only return a value of 0 (idle).

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::Execute

The `IDL_IDLBridge::Execute` procedure method causes the child IDL process to execute a given IDL command. There are two possible modes in which this can be done:

- **Synchronous** — IDL waits until the child process completes the specified operation before `IDL_IDLBridge::Execute` returns. (Execution will halt in the main process if an error is generated. This is the default operation.
- **Asynchronous** — The call to `IDL_IDLBridge::Execute` returns immediately, and the caller can use the `IDL_IDLBridge::Status` method to track its progress. In addition, the `IDL_IDLBridge::OnCallback` method (and `CALLBACK` procedure) will be called automatically when the command is completed. This mode of overlapped execution can be used to perform expensive computations and visualizations in parallel with the main IDL process. Asynchronous operation is specified via the `NOWAIT` keyword.

Note

A process that presents a user interface (such as a dialog in the child process or the workbench interface in the main process) will typically execute time-consuming commands asynchronously to allow access to the user interface during processing. If execution requires a noticeable amount of time (which can vary depending on the process and your expectations), specify the `NOWAIT` keyword to maintain user interface responsiveness during command execution.

Once `Execute` launches the child process only the `IDL_IDLBridge::Status` method can interact with the process. You can call `IDL_IDLBridge::SetVar` or `IDL_IDLBridge::GetVar` before or after, but not during command execution. Attempting to get variables from or pass variables to a currently executing child process will generate an error.

Warning

In asynchronous mode, IDL execution will throw an error in the parent IDL process if you attempt to modify variables or execute a second command (in the same child session) before execution of the first command completes. The error “The object's associated IDL process is currently busy.” appears. A child process performs asynchronous operations in the sense that it lets you continue to interact with the parent process or other child processes, but the child process itself executes commands synchronously. For an example of how to avoid such an error, see “[Avoiding Busy Execution Errors](#)” on page 5426.

Note

This method is disabled in IDL Virtual Machine mode.

Syntax

```
Obj->[IDL_IDLBridge::]Execute, IDLStmt [, /NOWAIT]
```

Arguments

IDLStmt

A string containing an IDL command to be executed by the child IDL process.

Keywords

NOWAIT

Set this keyword to cause `IDL_IDLBridge::Execute` to return immediately, rather than waiting for the child process to complete. When `NOWAIT` is set, the parent IDL process continues to execute in parallel with the child process.

Examples

The following example creates an `IDL_IDLBridge` object and executes a simple command to display data:

```
oBridge = OBJ_NEW('IDL_IDLBridge')
oBridge->Execute, 'WINDOW, XSIZE=300, YSIZE=300'
oBridge->Execute, 'TV, DIST(300)'
```

Note that the argument to the `Execute` method is always a string containing an IDL command. This command is parsed and executed by the child IDL process in the usual way—much as if it had been entered at the IDL command line by an interactive user.

When constructing a command string to pass to the `Execute` method, it is important to clearly delineate between the parent and child IDL processes, which are separate IDL instances and do not share a common environment. For example, assume that the parent process has a variable named `curindex` containing the numeric index of the current plot. In a standard IDL session, you could use the following simple IDL command to add the index value to a window title string:

```
WINDOW, TITLE='Process ' + STRING(curindex)
```

It might be tempting to send this command to the `IDL_IDLBridge` child process in order to achieve the same effect:

```
oBridge->Execute, $
  "WINDOW, TITLE='Process ' + STRING(curindex) "
```

This will fail however: `curindex` is a variable in the *parent* IDL process, but not in the *child* process. Instead, we must make a subtle alteration such that the string concatenation is performed by the parent rather than the child process:

```
oBridge->Execute, $
  "WINDOW, TITLE='Process " + STRING(curindex) + "' "
```

Alternatively, we could use the `IDL_IDLBridge::SetVar` method to send the `curindex` variable to the child process. This might be a better choice if the value of `curindex` was needed there for other purposes in addition to constructing a window title, but in this simple example, it is better to do the work locally.

Avoiding Busy Execution Errors

Calling the `Execute`, `GetVar` or `SetVar` method on a currently executing child process causes the parent IDL process to throw an error:

The object's associated IDL process is currently busy

To avoid this condition, use the `IDL_IDLBridge::Status` method to make sure the child process is in the idle state (0) before calling the `Execute` method:

```
IF (oBridge->Status() EQ 0) THEN $
  oBridge->Execute, 'IDLStmt'
```

Executing a Batch File in a Child Process

A child process can execute batch files in the same manner as the parent IDL process. For example, the following batch file, `plot06`, is in the IDL path:

```
oBridge = OBJ_NEW('IDL_IDLBRIDGE')
oBridge->EXECUTE, '@plot06'
```

However, your startup file is *not* automatically executed when a new IDL child process is created. To manually call your startup file, use the following code:

```
oBridge->EXECUTE, '@' + PREF_GET('IDL_STARTUP')
```

Note

See “[Examples](#)” on page 5412 for addition examples of using the `Execute` method.

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::GetProperty

The IDL_IDLBridge::GetProperty procedure method retrieves a property or group of properties for this object.

Syntax

Obj->[IDL_IDLBridge::] GetProperty [, *PROPERTY=variable*]

Arguments

None

Keywords

Any property listed under “[IDL_IDLBridge Properties](#)” on page 5418 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::GetVar

The `IDL_IDLBridge::GetVar` function copies the value of a variable from the child process to the parent process. The variable must exist in the child process at the `$MAIN$` level. See “[Examples](#)” on page 5430 for more information.

`IDL_IDLBridge::GetVar` is subject to the following limitations:

- Only scalar or array variables of numeric or string type can be transferred. Structures, pointers, and object references cannot be transferred between processes using the `IDL_IDLBridge` object.
- `IDL_IDLBridge::GetVar` makes a *copy* of the data in the parent process, which may affect the performance of your application if the amount of data involved is large. In such cases, the use of shared data files or shared memory ([SHMMAP](#) and [SHMVAR](#)) may offer a more efficient way to share data.

Note

It is not possible to call `GetVar` or `SetVar` when a child process is actively executing a command (when `IDL_IDLBridge::Status` equals 1).

Note

This method is disabled in IDL Virtual Machine mode.

Syntax

Result = *Obj*->[`IDL_IDLBridge::`]GetVar(*VarName*)

Return Value

Returns the value of the variable transferred from the child process.

Arguments

VarName

A string containing the name of the variable to be transferred from the child process.

Keywords

None

Examples

The `GetVar` method can return the value of a variable that exists at the `$MAIN$` level of the child process. In the following example, `GetVar` returns image data. Note that the `mrifile` variable and `data` variable are created in the child process as a result of executing the `Execute` statement.

```
; Create a child process.
oBridge=OBJ_NEW('IDL_IDLBridge')

; Access a file and pass it to the child process in a variable
; called file.
mriFile= FILEPATH('pdthorax124.jpg', $
    SUBDIRECTORY = ['examples', 'data'])

; Extract the image data in the child process into a
; variable named data.
oBridge->Execute, "READ_JPEG,'" + mriFile + "', data"

; Access the image data using GetVar and display it.
imgData = oBridge->GetVar('data')
IIMAGE, imgData
```

You can also access information about a child process using the `HELP` procedure. For example, if you set a breakpoint in a parent IDL process at a point where `IDL_IDLBridge` object status can be obtained (such as during an `Abort`, where you can access an `IDL_IDLBridge` object that is not actively executing a command), you can use `GetVar` to return `HELP` information as follows:

```
oBridge->Execute, 'HELP, /FULL, OUTPUT=x'
PRINT, oBridge->GetVar('x')
```

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::Init

The IDL_IDLBridge::Init method initializes an IDL_IDLBridge object, which provides a means of controlling the corresponding IDL child process.

Note

A startup file is *not* automatically executed when a child process is created. To manually run a startup file, see “[Executing a Batch File in a Child Process](#)” on page 5426 for more information.

Note

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW('IDL_IDLBridge' [, *PROPERTY=value*])

or

Result = *Obj*->[IDL_IDLBridge::]Init([, *PROPERTY=value*]) (In a subclass' Init method only)

Arguments

None

Keywords

Any property listed under “[IDL_IDLBridge Properties](#)” on page 5418 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::OnCallback

The IDL_IDLBridge::OnCallback procedure method is called automatically when an asynchronous command ends. By default the IDL_IDLBridge::OnCallback method will check if the **CALLBACK** property has been set, and if so, the method will automatically call the procedure indicated by the **CALLBACK** property.

If you are using a subclass of IDL_IDLBridge, you may want to override the IDL_IDLBridge::OnCallback method to provide your own functionality.

Note

This method is only called when executing an asynchronous command (when the **NOWAIT** keyword has been set).

When the asynchronous command is completed, aborted, or halted due to an error, the child IDL process calls back into the main IDL process. The main IDL process puts a callback event into the callback event queue for the bridge object. The callback queue for this bridge object is flushed (and the **CALLBACK** procedure or **OnCallback** method is called) when one of the following occurs:

- The widget event queue is flushed by IDL's widget event processing
- The user calls **WIDGET_EVENT**
- The user calls any IDL_IDLBridge method (except **Abort**)
- The user calls **OBJ_DESTROY**

Syntax

Obj->[IDL_IDLBridge::]OnCallback, *Status*, *Error*

Arguments

Status

The Status argument will be set to one of the integer values from the following table:

Value	Description	ERROR Argument
2	Completed command	Null string
3	Error halted execution	Descriptive error string
4	Aborted execution	Abort message

Note

Because the `OnCallback` method is only called when a command ends, values of `Status=0` (Idle) or `Status=1` (Executing) will never be returned. (See [IDL_IDLBridge::Status](#) for a list of all possible status values.)

Error

The *Error* argument will be set to a string corresponding to any error that may have occurred while executing the command in the slave process. As shown in the table above, if *Status* contains an error status (3), the *Error* argument returns a descriptive error string. If *Status* indicates an aborted status (4), *Error* returns an abort message. Otherwise, the *Error* argument will be set to a null string.

Keywords

None.

Examples

Although this method does not use the `OnCallback` method directly, setting the `IDL_IDLBridge` [CALLBACK](#) property causes this method to automatically initiate your callback procedure. The following example shows how to define a simple callback procedure.

1. Create a program file that contains the following code. This is the callback procedure:

```
PRO idl_idlbridge_example_callback, status, error, $
  oBridge, userdata

  ; Get the result of the FFT command from the child
  ; process and print min and max values.
  result = oBridge->GetVar('result')
  PRINT, 'FFT finished'
  PRINT, MIN(result), MAX(result)
  OBJ_DESTROY, oBridge
END
```

2. Enter all of the following lines at the command prompt. When the FFT command is complete, the specified callback procedure will be automatically called.

```
oBridge = Obj_New('IDL_IDLBridge', $
  CALLBACK='idl_idlbridge_example_callback')
; Compute a very long FFT.
```

```
oBridge->Execute, 'result = FFT(Randomu(1,1729,1729))', $  
    /NOWAIT  
; Our program keeps going while the FFT is being computed.  
Print, 'IDL command line is still active.'
```

Note

Also see the IDL_IDLBridge [“Examples”](#) on page 5412, which provide additional callback procedure samples.

IDL_IDLBridge:: SetProperty

The IDL_IDLBridge:: SetProperty procedure method sets the properties of an IDL_IDLBridge object.

Syntax

Obj->[IDL_IDLBridge::] SetProperty [, *PROPERTY*=*variable*]

Arguments

None

Keywords

Any property listed under “IDL_IDLBridge Properties” on page 5418 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::SetVar

The IDL_IDLBridge::SetVar function copies the value of a variable from the parent IDL process to the \$MAIN\$ level of the child process under the given name.

IDL_IDLBridge::SetVar is subject to the following limitations:

- Only scalar or array variables of numeric or string type can be transferred. Structures, pointers, and object references cannot be transferred between processes using the IDL_IDLBridge object.
- IDL_IDLBridge::SetVar makes a copy of the data in the child process, which may affect the performance of your application if the amount of data involved is large. In such cases, the use of shared data files or shared memory ([SHMMAP](#) and [SHMVAR](#)) may offer a more efficient way to share data.

Note

It is not possible to call GetVar or SetVar when a child process is actively executing a command (when [IDL_IDLBridge::Status](#) equals 1).

Note

This method is disabled in IDL Virtual Machine mode.

Syntax

Obj->[IDL_IDLBridge::]SetVar, *Name*, *Value*

Arguments

Name

A string containing the name of the variable to be set in the child process.

Value

A scalar or array variable of string or numeric type containing the data to be copied to the child process.

Keywords

None

Examples

The following example accesses image data from a JPEG file and passes it to a child process using SetVar.

```
mriFile= FILEPATH('pdthorax124.jpg', $
    SUBDIRECTORY = ['examples', 'data'])
READ_JPEG, mriFile, mriImg

; Create an IDL_IDLBridge object. Pass the image data (mriImg) to
; the child process in a variable named "image." Display the
; image data in a child process.
oBridge = OBJ_NEW("IDL_IDLBridge")
oBridge->SetVar, "image", mriImg
oBridge->Execute, "TVSCL, image"
```

Note

See [“Examples”](#) on page 5412 for additional examples.

Version History

6.3	Introduced
-----	------------

IDL_IDLBridge::Status

The `IDL_IDLBridge::Status` function method queries the state of an `IDL_IDLBridge` object. When the `NOWAIT` keyword is used with the `IDL_IDLBridge::Execute` method to execute IDL commands asynchronously, `IDL_IDLBridge::Status` can track the state of the child process.

Syntax

```
Result = Obj->[IDL_IDLBridge::]Status([ERROR=ErrorString])
```

Return Value

Returns an integer value indicating the status of the bridge object's corresponding child process. Descriptive error messages are returned in the variable specified by the `ERROR` keyword. Possible values are:

Return Value	Description	What ERROR Keyword Returns
0	Idle	Null string
1	Executing command	Null string
2	Completed command	Null string
3	Error halted execution	Descriptive error string
4	Aborted execution (<code>IDL_IDLBridge::Abort</code>)	Abort message

Arguments

None

Keywords

ERROR

A named variable that will contain a string value corresponding to the error that occurred while executing the command in the child process, if any. As shown in the [Return Value](#) table above, if `IDL_IDLBridge::Status` returns an error state (3), the `ERROR` keyword returns a descriptive error string. If this method returns an aborted

status (4), ERROR contains an abort message. If any other status is returned, the ERROR keyword sets its variable to a null string.

Examples

See the example, `idlbridge_demo_object.pro`, which is located in the `examples/doc/bridges` subdirectory of the IDL distribution. This example uses a CASE statement to determine what action to take based on information returned by the Status method. Run the example procedure by entering `idlbridge_demo_object` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT idlbridge_demo_object.pro`.

Status updates in this example rely on timer events. See [“Timer Events”](#) (Chapter 3, *User Interface Programming*) for more information on timers.

Note

For examples that use a callback procedure in addition to the Status method, see [“Examples”](#) on page 5412.

Version History

6.3	Introduced
-----	------------

IDL_Savefile

The IDL_Savefile object provides complete query and restore capabilities for IDL SAVE files. IDL SAVE files are binary format files created with the SAVE procedure; they can contain data or IDL routines. Using IDL_Savefile, you can retrieve information about the user, machine, and system that created the SAVE file, as well as the number and size of the various items contained in the file (variables, common blocks, routines, *etc.*). You can also selectively restore individual items from the SAVE file.

Use IDL_Savefile instead of the RESTORE procedure when you need to obtain detailed information on the items contained within a SAVE file without first restoring it, or when you wish to restore only selected items. Use RESTORE when you want to restore everything from the SAVE file using a simple interface.

Superclasses

None

Creation

See “[IDL_Savefile::Init](#)” on page 5448.

Properties

Objects of this class have no properties of their own.

Methods

This class has the following methods:

- [IDL_Savefile::Cleanup](#)
- [IDL_Savefile::Contents](#)
- [IDL_Savefile::Init](#)
- [IDL_Savefile::Names](#)
- [IDL_Savefile::Restore](#)
- [IDL_Savefile::Size](#)

In addition, this class inherits the methods of its superclasses (if any).

Example

Use the `IDL_Savefile` object to query the contents of a SAVE file containing data and selectively restore variables.

Typically, `IDL_Savefile::Contents` is the first method called on a savefile object; the information retrieved indicates the number of different types of items contained in the file (variables, routines, *etc.*). Next, a call to `IDL_Savefile::Names` is used to obtain the names of items of a specific type. `IDL_Savefile::Size` can be used to determine the size of variables in the file, and `IDL_Savefile::Restore` can be used to restore items for use within the current IDL session.

```

; Select a SAVE file to restore. The file contains volume data.
savefile = FILEPATH('cduskcD1400.sav', $
    SUBDIRECTORY=['examples', 'data'])

; Create a savefile object.
sObj = OBJ_NEW('IDL_Savefile', savefile)

; Query the contents of the SAVE file to determine the number of
; regular variables contained therein.
sContents = sObj->Contents()
PRINT, sContents.N_VAR

; IDL Prints:
; 3

; Retrieve the names of the variables in the SAVE file.
sNames = sObj->Names()
PRINT, sNames

; IDL Prints:
; DENSITY MASSFLUX VELOCITY

; Determine the size of the DENSITY variable.
sDensitySize = sObj->Size('density')
PRINT, sDensitySize

; IDL Prints:
; 3          30          30          15          1          13500

; Restore the DENSITY variable.
sObj->Restore, 'density'

; Display the volume data.
IVOLUME, density

```

IDL_Savefile Properties

Objects of this class have no properties of their own.

IDL_Savefile::Cleanup

The IDL_Savefile::Cleanup procedure method performs all necessary cleanup when the savefile object is destroyed. The SAVE file associated with the object is closed. In addition, all in-memory data structures created by IDL when cataloging the SAVE file are released.

Note

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDL_Savefile::]Cleanup *(In a lifecycle method only.)*

Arguments

None.

Keywords

None.

Version History

6.1	Introduced
-----	------------

IDL_Savefile::Contents

The IDL_Savefile::Contents function method returns a structure variable of type IDL_SAVEFILE_CONTENTS containing information about the associated SAVE file and its contents.

Syntax

Result = *Obj*->[IDL_Savefile::]Contents()

Return Value

Returns a structure variable of type IDL_SAVEFILE_CONTENTS containing information about the associated SAVE file and its contents. The structure contains the following fields:

Field	Type	Description
FILENAME	String	The file path to the open SAVE file.
DESCRIPTION	String	A user-supplied description string for the SAVE file, as specified using the DESCRIPTION keyword to the SAVE procedure. If the SAVE file lacks a user supplied description, this field contains a null string.
FILETYPE	String	A description of SAVE file type. For a standard SAVE file, this field will contain the string "Portable (XDR)". For a compressed SAVE file, this field will contain "Portable (XDR) compressed".
USER	String	The user name of the user who issued the SAVE command that created the SAVE file.
HOST	String	The name of the computer on which the SAVE file was created.
DATE	String	The date on which the SAVE file was created.

Table 34-1: Structure returned by IDL_Savefile::Contents

Field	Type	Description
ARCH	String	The value of the <code>!VERSION.ARCH</code> system variable field of the IDL installation that created the SAVE file.
OS	String	The value of the <code>!VERSION.OS</code> system variable field of the IDL installation that created the SAVE file.
RELEASE	String	The value of the <code>!VERSION.RELEASE</code> system variable field of the IDL installation that created the SAVE file.
N_COMMON	Integer	The number of main-level common blocks contained in the SAVE file.
N_VAR	Integer	The number of variables contained in the SAVE file.
N_SYSVAR	Integer	The number of system variables contained in the SAVE file.
N_PROCEDURE	Integer	The number of procedures contained in the SAVE file.
N_FUNCTION	Integer	The number of functions contained in the SAVE file.
N_OBJECT_HEAPVAR	Integer	The number of object heap variables contained in the SAVE file.
N_POINTER_HEAPVAR	Integer	The number of pointer heap variables contained in the SAVE file.
N_STRUCTDEF	Integer	The number of named structure definitions contained in the SAVE file. Named structure definitions are saved when a variable that references them is saved.

Table 34-1: Structure returned by `IDL_Savefile::Contents` (Continued)

Arguments

None.

Keywords

None.

Example

See [“Example”](#) on page 5441.

Version History

6.1	Introduced
-----	------------

IDL_Savefile::Init

The IDL_Savefile::Init function method initializes the savefile object. The SAVE file associated with the object is opened and scanned to construct an internal data structure representing the contents. The SAVE file remains open until the savefile object is destroyed — the user is not allowed to use the CLOSE procedure to close the SAVE file.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

```
Obj = OBJ_NEW('IDL_Savefile' [, Filename ] [, FILENAME=string]  
            [, /RELAXED_STRUCTURE_ASSIGNMENT])
```

or

```
Result = Obj->[IDL_Savefile::]Init() (In a lifecycle method only.)
```

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 (one) if initialization was successful, or 0 (zero) otherwise.

Arguments

Filename

A scalar string that contains the path name of the SAVE file from which information or data is to be recovered. If *Filename* is not present but the FILENAME keyword is specified, the keyword value is used. If neither the argument or the keyword is present, the file `idlsave.dat` in IDL's current working directory is used.

Keywords

FILENAME

Set this keyword equal to a scalar string that contains the path name of the SAVE file from which information or data is to be recovered.

Note

The FILENAME keyword duplicates the functionality of the *Filename* argument. If both are provided, the value specified by the *Filename* argument is used.

RELAXED_STRUCTURE_ASSIGNMENT

Normally, the `IDL_Savefile::Restore` method is unable to restore a structure variable if the definition of its type has changed since the SAVE file was written. This commonly occurs when objects are saved and the class structures of the objects change before they are restored in another IDL session. In such cases, `IDL_Savefile::Restore` issues an error and does not restore the item.

Set the RELAXED_STRUCTURE_ASSIGNMENT keyword when creating a savefile object to cause the `IDL_Savefile::Restore` method to restore such incompatible values using “relaxed structure assignment,” in which all possible data are restored using a field-by-field copy.

See the description of the `STRUCT_ASSIGN` procedure for additional details. “Relaxed Structure Assignment” (Chapter 16, *Application Programming*) provides a more in-depth discussion of the structure-definition process.

Version History

6.1	Introduced
-----	------------

IDL_Savefile::Names

The IDL_Savefile::Names function method returns names, or heap variable identifiers, of items contained within the SAVE file. By default, this method returns the names of variables in the file; keywords can be used to obtain identifiers for other items.

Syntax

```
Result = Obj->[IDL_Savefile::]Names( [, COUNT=variable]
    [, /COMMON_BLOCK | , COMMON_VARIABLE=string | , /FUNCTION |
    , /OBJECT_HEAPVAR | , /POINTER_HEAPVAR | , /PROCEDURE |
    , /STRUCTURE_DEFINITION | , /SYSTEM_VARIABLE] )
```

Return Value

If the SAVE file contains one or more items of the specified type, the return value is a string array containing the names of the items. If no items of the specified type exist, the return value is a scalar null string.

Note

If either the OBJECT_HEAPVAR or the POINTER_HEAPVAR keyword is specified, the return value is an integer array containing integer values that can be used to recover the heap variables stored in the SAVE file. If no heap variables of the specified type exist, the return value is 0 (zero).

Arguments

None.

Keywords

Note

The Names method will only return the names of one type of item in a single call. With the exception of the COUNT keyword, specifying more than one keyword may cause the method to return unexpected results (most often a null string).

COMMON_BLOCK

Set this keyword to retrieve the names of any main-level COMMON blocks contained in the SAVE file. A main-level COMMON block item in a SAVE file consists of the name of the block and the names of the variables contained within it. (The values of the variables are saved separately, as normal variables.)

COMMON_VARIABLE

Set this keyword to a scalar string that contains the name of a main-level COMMON block. The value returned by the Names method will be a string array containing the names of the variables contained in the specified COMMON block.

COUNT

Set this keyword equal to a named variable that will contain the number of identifiers returned. A value of 0 (zero) indicates that no identifiers of the specified type exist in the SAVE file, and that the result from the function is either a scalar null string or 0 (zero). A nonzero value indicates that the result is an array with that number of elements.

FUNCTION

Set this keyword to return the names of the compiled functions contained in the SAVE file.

OBJECT_HEAPVAR

Set this keyword to return the integer heap identifiers for the object heap variables contained in the SAVE file.

Note

It is rarely (if ever) necessary to restore heap variables directly; in almost all cases, restoring the regular variable that refers to the heap variable produces the desired effect. See [“Restoring Heap Variables Directly”](#) on page 5459 for a complete discussion of this topic.

Because the heap identifiers contained in the SAVE file being queried were assigned by the IDL session that saved the variables in the file, and not (in general) by the currently executing IDL session, the integers returned when OBJECT_HEAPVAR is set are *not* valid heap identifiers within the current IDL session. Because of this, the values are returned as plain integer values, and not as object references. The returned integer values can be supplied to the [IDL_Savefile::Restore](#) method (using the OBJECT_HEAPVAR keyword) to recover the object heap variables they reference.

Warning

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP_SAVE](#) for additional details on save attributes.

POINTER_HEAPVAR

Set this keyword to return the integer heap identifiers for the pointer heap variables contained in the SAVE file.

Note

It is rarely (if ever) necessary to restore heap variables directly; in almost all cases, restoring the regular variable that refers to the heap variable produces the desired effect. See “[Restoring Heap Variables Directly](#)” on page 5459 for a complete discussion of this topic.

Because the heap identifiers contained in the SAVE file being queried were assigned by the IDL session that saved the variables in the file, and not (in general) by the currently executing IDL session, the integers returned when `POINTER_HEAPVAR` is set are *not* valid heap identifiers within the current IDL session. Because of this, the values are returned as plain integer values, and not as pointer references. The returned integer values can be supplied to the `IDL_Savefile::Restore` method (using the `POINTER_HEAPVAR` keyword) to recover the pointer heap variables they reference.

Warning

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP_SAVE](#) for additional details on save attributes.

PROCEDURE

Set this keyword to return the names of the compiled procedures contained in the SAVE file.

STRUCTURE_DEFINITION

Structure definitions are saved by IDL as a side effect of saving structure variables that use the structure definition. Set this keyword to return the names of the structure definitions contained in the SAVE file.

SYSTEM_VARIABLE

Set this keyword to return the names of system variables contained in the SAVE file.

Example

See “[Example](#)” on page 5441.

Version History

6.1	Introduced
-----	------------

IDL_Savefile::Restore

The IDL_Savefile::Restore procedure method selectively restores individual items from the associated SAVE file.

Given the *identifier* for an item within the SAVE file, this method restores the item along with any additional items (such as structure definitions or heap variables) upon which the specified item depends. Use the [IDL_Savefile::Names](#) method to retrieve valid item identifiers.

By default, this method restores variables from the SAVE file; keywords can be used to restore items of other types.

Warning

There are several issues of which you should be aware when using this method to restore pointers or object references. See “[Notes on Restored Heap Variables](#)” on page 5456 for details.

Syntax

```
Obj->[IDL_Savefile::]Restore, SaveItem [, /COMMON] [, /FUNCTION]
  [, /NEW_HEAPVAR=variable] [, /OBJECT_HEAPVAR]
  [, /POINTER_HEAPVAR] [, /PROCEDURE]
  [, /RESTORED_OBJECTS=variable] [, /STRUCTURE_DEFINITION]
  [, /VERBOSE]
```

Arguments

SaveItem

A scalar string or string array of identifiers for items to be restored from the SAVE file. Identifiers are retrieved from the SAVE file using the [IDL_Savefile::Names](#) method.

Note

If either the OBJECT_HEAPVAR keyword or the POINTER_HEAPVAR keyword is specified, *SaveItem* must be an integer or integer array.

Keywords

COMMON

Set this keyword to restore the main-level COMMON block definitions specified by *SaveItem*.

Note

To restore both a COMMON block definition and the variables it references, restore the definition first, then restore the variables.

FUNCTION

Set this keyword to restore the function(s) specified by *SaveItem*.

NEW_HEAPVAR

Set this keyword equal to a named variable that will contain valid references for heap variables.

Note

This keyword is only valid when either the OBJECT_HEAPVAR or the POINTER_HEAPVAR keyword is specified.

The returned variable will have the same structure as *SaveItem*, with each element in the returned array corresponding to the same element in the *SaveItem* array. If OBJECT_HEAPVAR is specified, the returned variable will contain an array of object references; if POINTER_HEAPVAR is specified, the returned variable will contain an array of pointers. See [“Notes on Restored Heap Variables”](#) on page 5456 for additional information on restoring heap variables.

OBJECT_HEAPVAR

Set this keyword to restore the object heap variable(s) specified by *SaveItem*. To obtain valid references to the newly restored heap variables, you must also specify the NEW_HEAPVAR keyword. See [“Notes on Restored Heap Variables”](#) on page 5456 for additional information on restoring heap variables.

Warning

Only heap variables whose *save attribute* is set to True (the default) will be saved. See [HEAP_SAVE](#) for additional details on save attributes.

POINTER_HEAPVAR

Set this keyword to restore the pointer heap variable(s) specified by *SaveItem*. To obtain valid references to the newly restored heap variables, you must also specify the `NEW_HEAPVAR` keyword. See “Notes on Restored Heap Variables” on page 5456 for additional information on restoring heap variables.

Warning

Only heap variables whose *save attribute* is set to True (the default) will be saved. See `HEAP_SAVE` for additional details on save attributes.

PROCEDURE

Set this keyword to restore the procedure(s) specified by *SaveItem*.

RESTORED_OBJECTS

Set this keyword equal to a named variable that will contain an array of object references for any objects restored. The resulting list of objects is useful for programmatically calling the objects’ own restore methods (if any). If no objects are restored, the variable will contain a null object reference.

STRUCTURE_DEFINITION

Set this keyword to restore the named structure definition(s) specified by *SaveItem*. Named structure definitions are saved by IDL when a structure variable of that type is saved, and are restored when the variable is restored. The `STRUCTURE_DEFINITION` keyword allows you to restore just the definition, without the variable. This can be useful if you simply wish to create a new variable of the same type, and have no use for the saved variable data.

VERBOSE

Set this keyword to print an informative message for each item restored.

Note

Messages are only printed for top-level named variables. Heap variable references returned by the `NEW_HEAPVAR` keyword will not generate individual messages.

Notes on Restored Heap Variables

IDL variables can contain object or pointer references to *heap variables*, and these heap variables can contain other such references, either to themselves or to other heap

variables. There is no limit to the number of references that can be made to a given heap variable. This flexible design allows the construction of arbitrary data structures. (See [“Heap Variables”](#) (Chapter 17, *Application Programming*) for a more complete discussion of heap variables.)

While the RESTORE procedure handles all details related to restoring heap variables in a way that is transparent to the IDL user, the IDL_Savefile::Restore method provides greater flexibility and thus requires greater care. In particular, you should be aware of the following when using the IDL_Savefile::Restore method to restore heap variables:

1. An IDL_Savefile object will restore a given heap variable only once. This has implications for situations in which heap variables might be freed during the IDL_Savefile object’s lifetime. See [“Caution Regarding Restored Heap Variables”](#) on page 5458 for a complete discussion of this issue.
2. The IDL_Savefile object makes it possible to restore a heap variable independently of any regular IDL variable that might refer to it. This feature is described in detail in [“Restoring Heap Variables Directly”](#) on page 5459.

Understanding How Heap Variables are Restored

When the SAVE procedure saves variables that contain object or pointer references, the referenced heap variables are also saved. Internally, heap variables are represented by unique integers called *heap identifiers*, which are not generally accessible (or useful) to the IDL user. The unique integers used to identify heap variables are assigned by IDL when the variables are created, and are therefore only unique within that IDL session. A given heap variable will typically have completely different identifiers in two different IDL sessions.

When RESTORE later restores variables containing object or pointer references, the heap variables are likewise restored. Note, however, that the unique identifiers for the restored heap variables will be different from the identifiers they had in the IDL session in which the SAVE file was created. RESTORE handles the mapping of the old identifiers to the new ones internally, in a manner that is completely transparent to the IDL user. This allows the user to save and restore very complex data structures using the simple interface provided by the SAVE and RESTORE procedures.

Notice that when using SAVE and RESTORE, the user always deals with regular named variables. Heap variables are never explicitly saved or restored; they are referenced only indirectly, through the regular variables that refer to them. Working with restored heap variables directly would be inconvenient, because heap variables lack mnemonic names that allow for easy identification, and because the original

integer identifiers assigned by IDL when the heap variables were created have no meaning in the IDL session into which the variables are restored.

The `IDL_Savefile::Restore` method duplicates the behavior of the `RESTORE` procedure with regard to heap variables. That is, when a regular IDL variable that refers to a pointer or object heap variable is restored, the heap variable is also restored automatically. In addition, although it is rarely (if ever) useful, the `IDL_Savefile::Restore` method provides the ability to restore heap variables *without* restoring the IDL variables that refer to them. To accomplish this, the `IDL_Savefile` object allows you to retrieve the integer heap identifiers stored in the `SAVE` file, using the `POINTER_HEAPVAR` and `OBJECT_HEAPVAR` keywords to the `Names` method. Note that it would be incorrect to treat these identifiers as object or pointer references, because they are not valid references in the restoring IDL session. For this reason, they are reported as simple integer values. They have no special meaning outside of that given to them by the `IDL_Savefile` object for a given object instance.

Note

Restoring heap variables independently of regular variables is not recommended; the mechanism is provided only for completeness. See [“Restoring Heap Variables Directly”](#) on page 5459, for additional information.

Caution Regarding Restored Heap Variables

A given instance of an `IDL_Savefile` object will never restore a given pointer or object heap variable more than once, regardless of the number of pointers or object references that refer to that heap variable. While this reflects the expected behavior of pointers and object references — references to the same underlying quantity should all point to the same heap variable — you must take care in situations in which heap variables can be destroyed during the lifetime of the `IDL_Savefile` object.

To make the implications of this behavior clear, consider an example in which a `SAVE` file contains two variables, `A` and `B`, each of which is a pointer reference to the same underlying pointer heap variable. After instantiating an `IDL_Savefile` object named `obj` that refers to the `SAVE` file, execute the following IDL commands:

```
obj->RESTORE, 'a'  
PTR_FREE, a  
obj->RESTORE, 'b'
```

The result is that both restored variables `A` and `B` are dangling references to a non-existent heap variable. IDL does not re-create the heap variable when `B` is restored, because the `IDL_Savefile` object knows that it already restored it once. The process of freeing the heap variable using the `PTR_FREE` procedure does not influence the behavior of the `IDL_Savefile` object — as far as the savefile object is concerned, the

heap variable referred to by the variable B has already been restored, and should not be restored again.

Tip

To force IDL to create multiple instances of a single saved heap variable, you can create multiple instances of the `IDL_Savefile` object referring to the same `SAVE` file, and use each one to create a distinct and separate instance of the heap variable. We caution you that this sort of code can become confusing very quickly.

Restoring Heap Variables Directly

The `IDL_Savefile` object is designed to provide a way to query and restore *anything* contained within a `SAVE` file. As a result, the savefile object provides a mechanism for restoring heap variables independently of any regular IDL variables that may refer to them.

Note

The ability to directly restore heap variables independently of any referring regular variable is provided for completeness only. Restoring heap variables directly as described in this section is rarely (if ever) useful. The recommended way to restore a heap variable is to restore a regular IDL variable that refers to the heap variable.

To restore a heap variable independently of any regular variable, do the following:

1. Use either the `POINTER_HEAPVAR` or the `OBJECT_HEAPVAR` keyword (as appropriate) to the `IDL_Savefile::Names` method to retrieve the integer heap identifier of the heap variable.
2. Use either the `POINTER_HEAPVAR` or the `OBJECT_HEAPVAR` keyword (as appropriate) and the `NEW_HEAPVAR` keyword to the `IDL_Savefile::Restore` method to associate the restored heap variable with a new regular variable.

The following IDL code provides an example of how this might look:

```
; First create a pointer
myPtr = PTR_NEW('99.00')

; Create a SAVE file containing the pointer reference
SAVE, myPtr, FILE='ptr.sav'

; Reset the IDL session
.FULL_RESET_SESSION
```

```

; Create a savefile object from the SAVE file
sObj = OBJ_NEW('IDL_Savefile', 'ptr.sav')

; Retrieve the heap identifier of the saved pointer heap variable
ptrName = sObj->Names(/POINTER_HEAPVAR)

; Restore the heap variable, associating it with a new regular
; variable. Note that ptrName is (in this case) a one-element
; array.
sObj->Restore, ptrName[0], /POINTER_HEAPVAR, NEW_HEAPVAR=myNewPtr

; Display the contents of the new variable
PRINT, *myNewPtr

```

IDL Prints:

```
99.00
```

Tip

The above example is presented to depict the process of restoring a heap variable directly. It would have been much easier to simply restore the `myPtr` variable contained in the SAVE file.

Example

See “[Example](#)” on page 5441 for an example that restores variable data.

-----	------------

IDL_Savefile::Size

The IDL_Savefile::Size function method returns the size and type information for the specified variable, system variable, or heap variable in the SAVE file associated with the savefile object, if no keywords are set. If a keyword is set, IDL_Savefile::Size returns only the specified quantity.

Note

This method accepts the same keywords as the SIZE function, and returns the same information using the same formats. It differs only in that the argument is a string or integer identifier that specifies an item within a SAVE file, rather than an in-memory expression.

Syntax

Result = *Obj*->[IDL_Savefile::]Size(*SaveItem* [, *Keywords*])

Return Value

If no keywords are set, the Size method returns a vector of integer type. The first element is equal to the number of dimensions of *SaveItem*. This value is 0 (zero) if *SaveItem* is scalar or undefined. The next elements contain the size of each dimension, one element per dimension (none if *SaveItem* is scalar or undefined). After the dimension sizes, the last two elements contain the type code (zero if undefined) and the number of elements in *SaveItem*, respectively.

See “[SIZE](#)” on page 2385 for a listing of IDL type codes.

If a keyword is set, the Size method returns the specified information.

Arguments

SaveItem

A scalar value that specifies the item within the SAVE file for which size information is requested. If *SaveItem* is a string, it is the name of a variable or system variable contained in the SAVE file. If *SaveItem* is an integer, it is the unique heap variable identifier for a heap variable contained in the SAVE file.

Tip

Use the [IDL_Savefile::Names](#) function method to obtain the names or heap variable identifiers contained within a SAVE file before calling this method.

Keywords

IDL_Savefile::Size method accepts all of the keywords accepted by the [SIZE](#) function. See “[SIZE](#)” on page 2385 for details.

Example

See “[Example](#)” on page 5441.

[SIZE](#)

IDLcomActiveX

The IDLcomActiveX object class creates an IDL object that encapsulates an ActiveX control. IDL provides data type and other translation services, allowing IDL programs to access the ActiveX control's methods and properties using standard IDL syntax.

Note

IDL provides ActiveX support on Microsoft Windows platforms only.

For detailed information on using the IDLcomActiveX object, see [“Using ActiveX Controls in IDL”](#) (Chapter 4, *IDL Connectivity Bridges*).

Superclasses

[IDLcomIDispatch](#)

Subclasses

When an ActiveX control is instantiated, IDL creates a dynamic subclass of the IDLcomActiveX class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See [“ActiveX Control Naming Scheme”](#) (Chapter 4, *IDL Connectivity Bridges*) for details.

Creation

IDLcomActiveX objects are always created automatically by IDL, as a result of a call to the [WIDGET_ACTIVEX](#) function. They should never be created manually.

Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Methods

The IDLcomActiveX object class is a direct subclass of the IDLcomIDispatch class, and relies entirely on the superclass methods, providing none of its own.

Version History

-----	------------

IDLcomActiveX Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

Objects of this class inherit:

- [IDLcomIDispatch](#)

IDLcomIDispatch

The IDLcomIDispatch object class creates an IDL object that encapsulates a COM object. IDL provides data type and other translation services, allowing IDL programs to access the COM object's methods and properties using standard IDL syntax.

Note

IDL provides COM support on Microsoft Windows platforms only.

Note

COM objects encapsulated by IDLcomIDispatch objects must implement an IDispatch interface.

Note

You should be aware that COM, like C, stores array data in row-major format. IDL stores array data in column-major format. See “[Columns, Rows, and Array Majority](#)” (Chapter 15, *Application Programming*) for a detailed discussion of this issue and its implications for IDL application design.

For detailed information on using the IDLcomIDispatch object, see [Chapter 3, “Using COM Objects in IDL”](#) (*IDL Connectivity Bridges*).

Superclasses

None

Subclasses

When a COM object is instantiated, IDL creates a dynamic subclass of the IDLcomIDispatch class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See “[IDLcomIDispatch Object Naming Scheme](#)” (Chapter 3, *IDL Connectivity Bridges*) for details.

ActiveX controls are instantiated within IDL as a special subclass of the IDLcomIDispatch class named IDLcomActiveX.

Creation

See [IDLcomIDispatch::Init](#)

Properties

Objects of this class have the following properties. See “[IDLcomIDispatch Properties](#)” on page 5468 for details on individual properties.

- *KEYWORD*

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

- [IDLcomIDispatch::Init](#)
- [IDLcomIDispatch::GetProperty](#)
- [IDLcomIDispatch::SetProperty](#)

In addition to these methods, you can call the underlying COM object’s methods directly. See “[Method Calls on IDLcomIDispatch Objects](#)” (Chapter 3, *IDL Connectivity Bridges*) for details.

Note

The IDL object system uses method names to identify and call object lifecycle methods (Init and Cleanup). If the COM object underlying an IDLcomIDispatch object implements Init or Cleanup methods, they will be overridden by IDL’s lifecycle methods — the COM object’s methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for the IDLcomIDispatch object, so any methods of the underlying COM object that use these names will be inaccessible from IDL.

Version History

5.5	Introduced
-----	------------

IDLcomIDispatch Properties

IDLcomIDispatch objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “[IDLcomIDispatch::GetProperty](#)” on page 5469. Properties with the word “Yes” in the “Init” column of the property table can be set via “[IDLcomIDispatch::Init](#)” on page 5470. Properties with the word “Yes” in the “Set” column in the property table can be set via “[IDLcomIDispatch::SetProperty](#)” on page 5472.

KEYWORD

KEYWORD is a string containing the name of one of the underlying COM object’s properties, and *Variable* is the name of an IDL variable that will contain the retrieved property value. You can get multiple property values in a single statement by supplying multiple *KEYWORD=Variable* pairs.

Note

KEYWORD must map exactly to the full name of the underlying COM object’s property method. The partial keyword name functionality provided by IDL is not valid with IDLcomIDispatch objects.

IDLcomIDispatch::GetProperty

The IDLcomIDispatch::GetProperty function method is used to get properties from the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See [“Managing COM Object Properties”](#) (Chapter 3, *IDL Connectivity Bridges*).

Syntax

Obj->[\[IDLcomIDispatch::\]](#)GetProperty, [, *PROPERTY=variable*] [, *arg0, arg1, ...*]

Arguments

Because some of the underlying COM object's property methods may require arguments, the GetProperty method will accept optional arguments. The values of the arguments themselves will depend on the COM object that underlies the IDLcomIDispatch object.

Note

If arguments are required, you can only specify one property to retrieve in a given call to the GetProperty method.

Keywords

Any property listed under [“IDLcomIDispatch Properties”](#) on page 5468 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

5.5	Introduced
-----	------------

IDLcomIDispatch::Init

The IDLcomIDispatch::Init function method is used to initialize a given COM object and establish a link between the resulting IDL object and the IDispatch interface of the underlying COM object.

Syntax

Obj = OBJ_NEW('IDLcomIDispatch\$*ID_type*\$*ID*')
or

Result = *Obj*->[IDLcomIDispatch\$*ID_type*\$*ID*::]Init() (*In a lifecycle method only.*)

where *ID_type* is one of the following:

- CLSID if the object is identified by its COM class ID, or
- PROGID if the object is identified by its COM program ID,

and *ID* is the COM object's actual class or program identifier string. If the COM object's class identifier string is used to create the IDLcomIDispatch object, the braces ({ }) must be removed and the hyphens replaced by underscores. See [“IDLcomIDispatch Object Naming Scheme”](#) (Chapter 3, *IDL Connectivity Bridges*) for details.

Note

While COM objects incorporated into IDL are instances of the dynamic subclass created when the COM object is instantiated, they still expose the functionality of the class IDLcomIDispatch, which is the direct superclass of the dynamic subclass. All IDLcomIDispatch methods are available to the dynamic subclass.

Arguments

None.

Keywords

None.

Version History

5.5	Introduced
-----	------------

IDLcomIDispatch:: SetProperty

The IDLcomIDispatch::SetProperty function method is used to set properties for the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See “[Managing COM Object Properties](#)” (Chapter 3, *IDL Connectivity Bridges*) for details.

Syntax

Obj->[IDLcomIDispatch::]SetProperty [, *PROPERTY=value*]

Arguments

None.

Keywords

Any property listed under “[IDLcomIDispatch Properties](#)” on page 5468 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

IDLjavaObject

The IDLjavaObject class creates an IDL object that encapsulates a Java object. IDL provides data type and other translation services, allowing IDL programs to access the Java object's methods and properties using standard IDL syntax.

For detailed information on using the IDLjavaObject class, see [Chapter 5, “Using Java Objects in IDL”](#) (*IDL Connectivity Bridges*).

Superclasses

None

Creation

See [“IDLjavaObject::Init”](#) on page 5478.

Properties

The properties of this object depends on which Java object the IDLjavaObject class encapsulates. See [“IDLjavaObject Properties”](#) on page 5475 for more details.

Methods

This class has the following methods:

- [IDLjavaObject::GetProperty](#)
- [IDLjavaObject::Init](#)
- [IDLjavaObject::SetProperty](#)

In addition to these methods, you can call the underlying Java object's methods directly. See [“Method Calls on IDL-Java Objects”](#) (Chapter 5, *IDL Connectivity Bridges*) for details.

Note

The IDL object system uses method names to identify and call object *lifecycle methods* (Init and Cleanup). If the Java object underlying IDLjavaObject implements Init or Cleanup methods, they will be overridden by IDL's lifecycle methods — the Java object's methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for IDLjavaObject, so any methods of the underlying Java object that use these names will be inaccessible

from IDL. In Java, you can wrap these methods with different named methods to work around this limitation.

When a function, procedure, or Init method is called with an array as a parameter, the array is copied from IDL into Java space according to the data conversion rules (see “IDL-Java Bridge Data Type Mapping” (Chapter 5, *IDL Connectivity Bridges*)). After the Java call returns, any Java arrays are copied back to IDL arrays. The IDL array type after the “back-copy” will be the same type as that of the IDL array before the call.

Note

The SetProperty method does *not* copy arrays back from Java.

Note that this back-copy could cause some downcasting. For example, if you have an array of IDL bytes, you can call a Java method that accepts an array of longs. When the data are back-copied, the array of longs is cast to an array of bytes. If the Java method has changed one of the longs to a value greater than 255 (the upper limit of a byte), the long will be cast to some unexpected value. To avoid downcasting issues, IDL-Java programmers should know their data and make sure types in IDL and Java match as closely as possible.

Examples

See Chapter 5, “Using Java Objects in IDL” (*IDL Connectivity Bridges*).

Version History

6.0	Introduced
-----	------------

IDLjavaObject Properties

The property name of an instance of `IDLjavaObject` is passed to the IDL Java subsystem and is used in conjunction with the Java reflection API to access the related data member on the underlying object. The data member (property) is identified through the arguments to the [IDLjavaObject::GetProperty](#) and [IDLjavaObject::SetProperty](#) methods.

IDLjavaObject::GetProperty

The IDLjavaObject::GetProperty procedure method retrieves properties (known as data members in Java) from the Java object that underlies the IDLjavaObject. The Java object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See “[Managing IDL-Java Object Properties](#)” (Chapter 5, *IDL Connectivity Bridges*).

Syntax

```
Obj->[IDLjavaObject::]GetProperty [, PROPERTY=variable]
```

Arguments

None

Keywords

PROPERTY

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

Note

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

The *variable* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See “[IDL-Java Bridge Data Type Mapping](#)” (Chapter 5, *IDL Connectivity Bridges*) for more information.

Note

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

Version History

6.0	Introduced
-----	------------

IDLjavaObject::Init

The IDLjavaObject::Init function method instantiates the given Java object and establishes a link between the resulting IDL object with the underlying Java object.

Note

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: the Init method can be called from within the Init method of a subclass.

Syntax

```
Obj = OBJ_NEW('IDLjavaObject$JAVACLASSNAME', JavaClassName[, Arg1, ...])
```

where *JAVACLASSNAME* is a case-insensitive string representing the Java class to be instantiated, see “[IDL-Java Bridge Architecture](#)” (Chapter 5, *IDL Connectivity Bridges*) for more information. All periods in *JAVACLASSNAME* must be converted to underscores.

Return Value

Returns an object reference to the newly-created object if initialization is successful, or a null object if initialization fails.

Arguments

JavaClassName

A string representing the Java class to be instantiated. See “[Java Class Names in IDL](#)” (Chapter 5, *IDL Connectivity Bridges*) for more details.

Arg1, ...

Additional arguments as required by the constructor. These arguments are passed to the underlying Java constructor. Arguments may be IDL primitive types, IDL strings, IDLJavaObjects, and arrays of the previous types. See “[IDL-Java Bridge Data Type Mapping](#)” (Chapter 5, *IDL Connectivity Bridges*) for more information.

Keywords

None

Version History

6.0	Introduced
-----	------------

IDLjavaObject:: SetProperty

The IDLjavaObject::SetProperty procedure method sets properties (known as data members in Java) for the Java object that underlies an instance of IDLjavaObject. The Java object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See “[Managing IDL-Java Object Properties](#)” (Chapter 5, *IDL Connectivity Bridges*) for more details.

Syntax

```
Obj->[IDLjavaObject::]SetProperty [, PROPERTY=value]
```

Arguments

None

Keywords

PROPERTY

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

Note

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

The *value* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See “[IDL-Java Bridge Data Type Mapping](#)” (Chapter 5, *IDL Connectivity Bridges*) for more information.

Note

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

Version History

-----	------------

Overview of Multi-Monitor Support

The `IDLsysMonitorInfo` object returns information about display monitors available to IDL. This information allows you to create applications that can run in single- or multi-monitor environments.

Information returned by the `IDLsysMonitorInfo` object can be used by any IDL application to control window position.

Monitor information is collected for the default display system. On UNIX systems, you can direct the object to collect the information on a specific X Display connection. Information in the `IDLsysMonitorInfo` object is read-only, except for the X Display name.

The following sections provide useful information in dealing with monitor and multi-monitor support and configuration.

Arrays of Monitor Information

The `IDLsysMonitorInfo` class provides function methods that return arrays containing monitor information. Each row in an array contains information for a specific monitor. Use a particular row index when accessing each array to retrieve information for a particular monitor.

For example, if there are at least two monitors on the system and monitor number 1 (0-based) is the monitor the application wishes to use to display a GUI:

```
res = oMonitorInfo->GetResolutions()
rect = oMonitorInfo->GetRectangles()
GUIMonitorResolution = res[* ,1]
GUIMonitorRectangle = rect[* ,1]
```

If there is only one monitor on the system, the function methods return a single-row array or vector whose length depends on the particular method.

Restoring Monitor Information Objects

When a monitor information object is restored from a SAVE file, it collects monitor information from the system that is restoring the object, taking into account any saved display name in the `DISPLAY_NAME` property. Thus, the object updates itself to reflect the monitor information for the system restoring the object. Applications performing the restore will likely need to retrieve the monitor information for the current system and reconfigure themselves accordingly.

Configuration Changes and Active IDL Applications

On Windows systems it is possible to reconfigure the operating system to add or remove monitors while an IDL application is running. `IDLsysMonitorInfo` returns monitor information for the configuration that is in effect at the time the information is requested. If an IDL application wishes to take into account any monitor configuration changes made while the application is running, it should re-query the information from this class immediately prior to creating any windows that require this information for positioning.

On UNIX systems, IDL does not detect configuration changes. You will need to restart IDL if you change the configuration.

X Windows and XINERAMA Awareness

On some UNIX systems, the XINERAMA X Windows extension is used by X servers to present multiple Screens/monitors to the X client application as a single X Screen that covers all the monitors, much like the extended desktop on Windows systems. Because the XINERAMA extension is not available on all UNIX platforms, the `IDLsysMonitorInfo` class returns different information depending on the available XINERAMA support (in IDL 6.3, only Mac OS X and some Linux distributions support XINERAMA). Additionally, XINERAMA includes queries that the X client application can use to learn about the location and size of the monitors. XINERAMA-aware client applications have access to additional information about the monitor configuration. Thus, you can retrieve the maximum amount of monitor

configuration information if both client and server support XINERAMA. Table 10.2 details the information available in all possible client-server combinations.

Client supports XINERAMA?	Server supports XINERAMA?	
	Yes	No
Yes — IDL running on Linux, OS X	IDL detects extended desktop with monitor information for each physical monitor.	IDL detects independent desktops with monitor information for each physical monitor.
No — IDL running on other UNIX platforms	IDL detects extended desktop with monitor information for single desktop spanning all monitors. Individual monitor information is not available.	IDL detects independent desktops with monitor information for each physical monitor

Table 34-2: Possible XINERAMA Client/Server Combinations

For more information on multi-monitor support and various platforms, see [“Multi-Monitor Configurations”](#) (*Using IDL*).

IDLsysMonitorInfo Properties

IDLsysMonitorInfo objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via [IDLsysMonitorInfo::GetProperty](#).

Properties with the word “Yes” in the “Init” column of the property table can be set via [IDLsysMonitorInfo::Init](#). Properties with the word “Yes” in the “Set” column in the property table can be set via [IDLsysMonitorInfo::SetProperty](#).

Note

For a discussion of the property description tables shown below, see [“About Object Property Descriptions”](#) on page 3255.

Objects of this class have the following properties.

- [DISPLAY_NAME](#)

DISPLAY_NAME

This property contains the X Windows server display name string of the monitor that this object queries for monitor information. The default value is the empty string (“”). This property may be stored and retrieved on Windows systems, but has no effect on the object. On UNIX systems, if the value of the property is an empty string, the object retrieves the monitor information from the default X Display connection in effect for IDL. If the object cannot contact the X server specified by this property, no error is issued, but all the “Get” methods for this class return no data, as detailed in the description for each method.

Property Type	Scalar string		
Name String	<i>not displayed</i>		
Get: Yes	Set: Yes	Init: Yes	Registered: No

IDLsysMonitorInfo::Cleanup

The IDLsysMonitorInfo::Cleanup procedure method performs all cleanup on the object.

Note

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object creation and destruction. This means that in most cases, you cannot call the Cleanup method directly. One exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Init or Cleanup method of the subclass.

Syntax

OBJ_DESTROY, *Obj*

or

Obj->[IDLsysMonitorInfo::]Cleanup *(In a lifecycle method only.)*

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::GetMonitorNames

The `IDLsysMonitorInfo::GetMonitorNames` function method retrieves, into an array, the X Window System Display name strings associated with each monitor on the system. There is one name string in the array for each monitor. The contents of the array of strings depends on the X server configuration. If the server is configured as an extended desktop, the same X Display name string is returned in each string in the array. If the server is configured to use multiple X Screens, the X Display name corresponding to each X Screen is returned in the array. The function returns a one-element array containing an empty IDL string if there are no monitors available on the system, or if the `DISPLAY_NAME` property does not refer to a valid X server connection. On Windows systems, this function returns an array of empty strings, one for each monitor, since display name strings are not useful on Windows.

Syntax

Result = *Obj*->[IDLsysMonitorInfo::]GetMonitorNames()

Return Value

Returns an array of strings, one for each monitor.

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::GetNumberOfMonitors

The IDLsysMonitorInfo::GetNumberOfMonitors function method retrieves the number of monitors available on the system. The function returns zero if there are no monitors available on the system, or if the DISPLAY_NAME property does not refer to a valid X server connection.

Syntax

Result = *Obj*->[IDLsysMonitorInfo::]GetNumberOfMonitors()

Return Value

Returns the number of monitors available on the system.

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::GetPrimaryMonitorIndex

The `IDLsysMonitorInfo::GetPrimaryMonitorIndex` function method retrieves the index of the monitor that is considered the system's primary monitor. This index can be used to index the arrays returned by other function methods in this class that return monitor information.

A monitor is considered *primary* if the system specifically designates it as the primary monitor. If no such designation is made, the monitor containing the desktop origin (0, 0) is considered the primary monitor. On UNIX systems that use multiple X Screens, the primary monitor is the one that is associated with the default Screen of the X Display connection.

Syntax

Result = *Obj*->[IDLsysMonitorInfo::]GetPrimaryMonitorIndex()

Return Value

Returns the index of the primary monitor as an integer, or -1 if there are no monitors available on the system, or if the `DISPLAY_NAME` property does not refer to a valid X server connection.

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::GetProperty

The IDLsysMonitorInfo::GetProperty procedure method retrieves the value of a property or group of properties.

Syntax

Obj->[IDLsysMonitorInfo:]GetProperty [, PROPERTY=*variable*]

Arguments

None

Keywords

Any property listed under [IDLsysMonitorInfo Properties](#) that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::GetRectangles

The IDLsysMonitorInfo::GetRectangles function method retrieves the monitor coordinate rectangles.

Syntax

Result = *Obj*->[IDLsysMonitorInfo::]GetRectangles([, /EXCLUDE_TASKBAR])

Return Value

Returns the monitors' coordinate rectangles. A coordinate rectangle refers to a 4-element array of the form $[x,y,w,h]$, where x and y are the origin at the upper-left corner of the rectangle and where w and h are the width and height of the rectangle.

There is one row returned in the array for each monitor, each column in the array contains a value for a component of each monitor (see Table 10-3 for the array columns).

Array Column	Content
First Column	Contains the x coordinate of the upper-left pixel of the monitor
Second Column	Contains the y coordinate of the upper-left pixel
Third Column	Contains the monitor width (w) in pixels
Fourth Column	Contains the monitor height (h) in pixels

Table 34-3: Array Columns of the Monitor's Coordinate Rectangles

If no monitors are available on the system, or if the DISPLAY_NAME property does not refer to a valid X server connection, IDLsysMonitorInfo::GetRectangles returns a four-element IDL long array containing zero values.

Arguments

None

Keywords

EXCLUDE_TASKBAR

Set this keyword to cause the returned monitor rectangle information to *not* include the region of the monitor occupied by the Windows task bar. This keyword is supported on the Windows platform only and is ignored on all other platforms.

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::GetResolutions

The IDLsysMonitorInfo::GetResolutions function method retrieves the monitor resolutions (pixel sizes) as a $[2, n]$ single-precision floating-point array in terms of centimeters per pixel. There is one row in the array for each monitor.

Syntax

Result = *Obj*->[IDLsysMonitorInfo::]GetResolutions()

Return Value

Returns the monitor resolutions. The first column is the x resolution and the second column is the y resolution. The function returns a two-element single-precision floating-point array containing zero values if there are no monitors available on the system, or if the DISPLAY_NAME property does not refer to a valid X server connection.

Arguments

None

Keywords

None

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::Init

The IDLsysMonitorInfo::Init function method initializes a monitor information object.

Note

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means in most cases, you cannot call the Init method directly. One exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

Syntax

Obj = OBJ_NEW([IDLsysMonitorInfo](#) [PROPERTY=*value*])

or

Result = *Obj*->[[IDLsysMonitorInfo::](#)]Init([PROPERTY=*value*]) (Only in a subclass' Init method)

Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

Arguments

None

Keywords

Any property listed under [IDLsysMonitorInfo Properties](#) that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

IDLsysMonitorInfo::IsExtendedDesktop

The IDLsysMonitorInfo::IsExtendedDesktop function method returns a Boolean value (0 or 1 as an IDL integer) that indicates if the display system is configured as an extended desktop across two or more monitors. An extended desktop uses a single coordinate system to address pixels across two or more monitors.

Syntax

Result = *Obj*->[IDLsysMonitorInfo::]IsExtendedDesktop()

Return Value

The return values is true (1) if:

- the desktop is extended across two or more monitors

The return value is false (0) if:

- there are fewer than two monitors on the system
- on an X Windows configuration that uses multiple X Screens

For X Windows configurations, the return value is false (0) if:

- there are no monitors available on the system
- the DISPLAY_NAME property does not refer to a valid X server connection

Arguments

None

Keywords

None

Version History

-----	------------

IDLsysMonitorInfo:: SetProperty

The IDLsysMonitorInfo:: SetProperty procedure method sets the value of a property or group of properties for the object.

Syntax

Obj->[[IDLsysMonitorInfo::](#) SetProperty[, PROPERTY=*value*]

Arguments

None

Keywords

Any property listed under [IDLsysMonitorInfo Properties](#) that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

6.3	Introduced
-----	------------

TrackBall

A TrackBall object translates widget events from a draw widget (created with the WIDGET_DRAW function) into transformations that emulate a virtual trackball (for transforming object graphics in three dimensions).

This object class is implemented in the IDL language. Its source code can be found in the file `trackball__define.pro` in the `lib` subdirectory of the IDL distribution.

Superclasses

None

Creation

See “[TrackBall::Init](#)” on page 5504.

Properties

Objects of this class have the following properties. See “[TrackBall Properties](#)” on page 5502 for details on individual properties.

- [AXIS](#)
- [CONSTRAIN](#)
- [MOUSE](#)

In addition, objects of this class inherit the properties of all superclasses of this class.

Methods

This class has the following methods:

- [TrackBall::Init](#)
- [TrackBall::Reset](#)
- [TrackBall::Update](#)

In addition, this class inherits the methods of its superclasses (if any).

Version History

5.0	Introduced
-----	------------

TrackBall Properties

TrackBall objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Init” column of the property table can be set via “[TrackBall::Init](#)” on page 5504.

Note

For a discussion of the property description tables shown below, see “[About Object Property Descriptions](#)” on page 3255.

Objects of this class have the following properties.

- [AXIS](#)
- [CONSTRAIN](#)
- [MOUSE](#)

AXIS

An integer value that indicates the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.
- 2 = Rotate only around the *Z* axis (this is the default).

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

CONSTRAIN

A boolean value that indicates whether the trackball transformations are to be constrained about the axis specified by the **AXIS** keyword. The default is not to constrain the transformations.

Property Type	Boolean		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

MOUSE

An integer value that indicates which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

Property Type	Integer		
Name String	<i>not displayed</i>		
Get: No	Set: No	Init: Yes	Registered: No

TrackBall::Init

The `TrackBall::Init` function method initializes the `TrackBall` object.

Syntax

```
Obj = OBJ_NEW('TrackBall', Center, Radius [, PROPERTY=value])
```

or

```
Result = Obj->[TrackBall::]Init( Center, Radius )    (In a lifecycle method only.)
```

Note

Keywords can be used in either form. They are omitted in the second form for brevity.

Arguments

Center

A two-element vector, $[X, Y]$, specifying the center coordinates of the trackball. X and Y should be specified in device units.

Radius

The radius of the trackball, specified in device units.

Keywords

Any property listed under “[TrackBall Properties](#)” on page 5502 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

Version History

5.0	Introduced
-----	------------

TrackBall::Reset

The TrackBall::Reset procedure method resets the state of the TrackBall object.

Syntax

```
Obj->[TrackBall::]Reset, Center, Radius [, AXIS={0 | 1 | 2}] [, /CONSTRAIN]  
[, MOUSE={1 | 2 | 4}]
```

Arguments

Center

A two-element vector, [X, Y], specifying the center coordinates of the trackball. X and Y should be specified in device units.

Radius

The radius of the trackball, specified in device units.

Keywords

AXIS

Set this keyword to an integer value to indicate the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the X axis.
- 1 = Rotate only around the Y axis.
- 2 = Rotate only around the Z axis (this is the default).

CONSTRAIN

Set this keyword to indicate that the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

Version History

5.0	Introduced
-----	------------

TrackBall::Update

The `TrackBall::Update` function method updates the state of the `TrackBall` object based on the information contained in the input widget event structure. The return value is nonzero if a transformation matrix is calculated as a result of the event, or zero otherwise.

Syntax

```
Result = Obj->[TrackBall::]Update( sEvent [, MOUSE={1 | 2 | 4}]  
    [, TRANSFORM=variable] [, TRANSLATE] )
```

Arguments

sEvent

The widget event structure.

Keywords

MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

TRANSFORM

Set this keyword to a named variable that will contain a 4 x 4 element floating-point array if a new transformations matrix is calculated as a result of the widget event.

TRANSLATE

Set this keyword to indicate that the trackball movement should be constrained to translation in the *X-Y* plane rather than rotation about an axis.

Example

The example code below provides a skeleton for a widget-based application that uses the `TrackBall` object to interactively change the orientation of graphics.

Create a trackball centered on a 512x512 pixel drawable area, and a view containing the model to be manipulated:

```

xdim = 512
ydim = 512
wBase = WIDGET_BASE()
wDraw = WIDGET_DRAW(wBase, XSIZE=xdim, YSIZE=ydim, $
    GRAPHICS_LEVEL=2, /BUTTON_EVENTS, $
    /MOTION_EVENTS, /EXPOSE_EVENTS, RETAIN=0 )
WIDGET_CONTROL, wBase, /REALIZE
WIDGET_CONTROL, wDraw, GET_VALUE=oWindow

oTrackball = OBJ_NEW('Trackball', [xdim/2.,ydim/2.], xdim/2.)
oView = OBJ_NEW('IDLgrView')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
XMANAGER, 'TrackEx', wBase

```

You must handle the trackball updates in the widget event-handling code. As the trackball transformation changes, update the transformation for the model object, and redraw the view:

```

PRO TrackEx_Event, sEvent
...
bHaveXform = oTrackball->Update( sEvent, TRANSFORM=TrackXform )
IF (bHaveXform) THEN BEGIN
oModel->GetProperty, TRANSFORM=ModelXform
oModel->SetProperty, TRANSFORM=ModelXform # TrackXform
oWindow->Draw, oView
ENDIF
...
END

```

Example Code

For a complete example, see the file `surf_track.pro`, located in the `examples/doc/objects` subdirectory of the IDL distribution. Run the example procedure by entering `surf_track` at the IDL command prompt or view the file in an IDL Editor window by entering `.EDIT surf_track.pro`.

The `SURF_TRACK` procedure uses IDL widgets to create a graphical user interface to an object tree, creates a surface object from user-specified data (or from default data, if none is specified), and places the surface object in an IDL draw widget. The

SURF_TRACK interface allows the user to specify several attributes of the object hierarchy via pulldown menus.

Part III: Appendices

Appendix A

IDL Direct Graphics Devices

The following topics are covered in this appendix:

Supported Devices	5514	The PCL Device	5572
Devices with Scalable Pixels	5516	The Printer Device	5574
Keywords Accepted by the IDL Devices	5517	The PostScript Device	5575
Window Systems	5559	The Regis Terminal Device	5589
Printing Graphics Output Files	5562	The Tektronix Device	5590
The CGM Device	5565	The Microsoft Windows Device	5592
The HP-GL Device	5567	The X Windows Device	5593
The Metafile Display Device	5569	The Z-Buffer Device	5603
The Null Display Device	5571		

Supported Devices

IDL Direct Graphics support graphic output to the devices listed below:

Device Name	Description
CGM	Computer Graphics Metafile
HP	Hewlett-Packard Graphics Language (HP-GL)
METAFILE	Windows Metafile Format (WMF)
NULL	No graphics output
PCL	Hewlett-Packard Printer Control Language (PCL)
PRINTER	System printer
PS	PostScript
REGIS	Regis graphics protocol (DEC systems only)
TEK	Tektronix compatible terminal
WIN	Microsoft Windows
X	X Window System
Z	Z-buffer pseudo device

Table A-4: IDL Graphics Output Devices

Each of these devices is described in a section of this chapter. The `SET_PLOT` procedure can be used to select the graphic device to which IDL directs its output. IDL Object Graphics does not rely on the concept of a current graphics device.

The `DEVICE` procedure controls the graphic device-specific functions. An attempt has been made to isolate all device-specific functions in this procedure. `DEVICE` controls the graphics device currently selected by `SET_PLOT`. When using `DEVICE`, it is important to make sure that the current graphics device is the one you intend to use. This is because most of the devices have different keywords—you will most likely get a “keyword ... not allowed in call to: Device” error if you call `DEVICE` when the wrong device is selected.

Obsolete Graphics Devices and Device Keywords

The following graphics devices are obsolete:

- LJ
- MAC

For information on obsolete graphics devices, See [Appendix I, “IDL API History”](#).

The following graphics device keywords are obsolete:

- DEPTH
- FONT

For information on obsolete keywords, see [Appendix I, “IDL API History”](#).

Devices with Scalable Pixels

For most direct graphics display devices, pixels are of a fixed size and the number of pixels available depends on the display resolution of the device. For such devices, the array of pixels written to the screen will be the same size as the image array.

Some direct graphics devices have the ability to place an image with any number of pixels into an area of arbitrary size. Such devices are said to have scalable pixels, because there is no direct connection between the number of pixels in the image and the physical space it occupies in the displayed image. The Computer Graphics Metafile (CGM) and PostScript (PS) devices fall into this category.

When the current image device has scalable pixels, IDL sets the first bit of the `!D.FLAGS` system variable field. The following IDL statement can be used to determine if the current device has scalable pixels:

```
SP = !D.FLAGS AND 1
```

SP will be nonzero if the device has scalable pixels. When displaying an image on a device with scalable pixels, the default is to use the entire display surface for the image. The `XSIZE` and `YSIZE` keywords can be used to override this default and specify the width and height of the desired display area.

The `XSIZE` and `YSIZE` keywords should also be used when positioning images with the *Position* argument to the `TV` or `TVSCL` routines. The *Position* argument normally uses the size of the image in pixels to determine the placement of the image, but this is not possible for devices with scalable pixels. Instead, the default for such devices is to fill the entire available display area. However, if `XSIZE` and `YSIZE` are specified along with the *Position* argument, `TV` or `TVSCL` will use them to determine image placement.

Keywords Accepted by the IDL Devices

The following table indicates which keywords are accepted by the DEVICE procedure. The NULL device is not listed as it accepts no keywords. Details of the various keywords (listed alphabetically) can be found in the following pages.

Note

Most keywords to the DEVICE procedure are sticky — that is, once you set them, they remain in effect until you explicitly change them again, or end your IDL session. The exceptions are keywords used to return a value from the system (GET_FONTNAMES, for example) and those that perform a one-time-only operation (CLOSE_FILE, for example).

Table A-5: Keywords accepted by the IDL devices (Continued)

Keywords accepted by the DEVICE command are described below. A list of devices that accept the keyword is included in parentheses below the keyword name.

AVANTGARDE

(PS)

Set this keyword to select the ITC Avant Garde PostScript font.

AVERAGE_LINES

(REGIS)

Controls the method of writing images to the VT240. If this keyword is set, (default setting), even and odd pairs of image lines are averaged and written to a single line. If clear, each image line is written to the screen. See the discussion below. This keyword has no effect when using a VT300 series terminal.

BINARY

(CGM)

Set this keyword to set the encoding type for the CGM output file to binary.

BITS_PER_PIXEL

(PS)

Set this keyword to an integer that specifies the number of bits used to represent a pixel in a bitmap image included in a PostScript file. Allowed values are 1, 2, 4, or 8 bits per pixel, representing 2, 4, 16, or 256 shades. By default, BITS_PER_PIXEL is set to 4.

Note

Using more bits per pixel gives higher resolution at the cost of generating larger files.

When writing TrueColor images to a PostScript file, the BITS_PER_PIXEL value applies to each *channel* of the image. Thus, to write a 24-bit image, which consists of three 8-bit image planes, set BITS_PER_PIXEL=8.

See [“TrueColor Images”](#) on page 5578 for additional details and an example.

BKMAN

(PS)

Set this keyword to select the ITC Bookman PostScript font.

BOLD

(PS)

Set this keyword to specify that the bold version of the current PostScript font should be used.

BOOK

(PS)

Set this keyword to specify that the book version of the current PostScript font should be used.

BYPASS_TRANSLATION

(WIN, X)

Set this keyword to bypass the translation tables, allowing direct specification of color indices. See [“Color Translation”](#) on page 5598. Pixel values read via the TVRD function are not translated if this keyword is set, and the result contains the byte value of the actual pixel values present in the display.

By default, the color translation tables are bypassed if the visual type is TrueColor or the visual type is DirectColor with a private colormap.

This keyword is accepted by the WIN device (for compatibility with the X device), but has no effect when set.

CLOSE

(Z)

Set this keyword to deallocate the memory used by the Z-buffer. The Z-buffer device is reinitialized if subsequent graphics operations are directed to the device.

CLOSE_DOCUMENT

(PRINTER)

Set this keyword to have IDL send any buffered output to the currently selected printer. This keyword is applicable only when the printer device is selected. See [“The Printer Device”](#) on page 5574 for details.

CLOSE_FILE

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Set this keyword to have IDL output any buffered commands and close the current graphics file.

Caution: If you close the output file and then cause IDL to produce more output (e.g., by executing a new PLOT command), IDL will open the file again, causing the contents of the recently closed file to be lost. To avoid this, use the FILENAME keyword to specify a different file name or use SET_PLOT to disable the graphics driver, or be sure to print the closed output file before creating more output.

See the discussion of printing output files in [“Printing Graphics Output Files”](#) on page 5562.

CMYK

(PS)

Set this keyword to generate PostScript output using the CMYK (cyan, magenta, yellow, and black) color model. The default PostScript color model is RGB (red, green, blue). PostScript CMYK files require a PostScript Language Level 2 interpreter. Therefore, when this keyword is set, the LANGUAGE_LEVEL keyword value is set to 2. See [“CMYK Output”](#) on page 5579 for additional information on CMYK output with a color PostScript device.

COLOR

(PCL, PS)

Set this keyword to enable color PCL or PostScript output. See [“The PCL Device”](#) on page 5572 or [“The PostScript Device”](#) on page 5575.

COLORS

(CGM, TEK)

This keyword specifies the maximum number of colors and the size of the color table used for output. The value of the system variable fields !D.N_COLORS and !D.TABLE_SIZE are set to this value and !P.COLOR is set to one less than this value.

For Tektronix Terminals Only

This keyword sets the number of colors supported by a 4100 series terminal. For example, if your terminal has 4-bit planes, the number of colors is $2^4 = 16$:

```
DEVICE, COLORS = 16
```

Valid values of this parameter are: 2, 4, 8, 16, or 64; other values will cause problems. Some Tektronix terminals will not operate properly if this parameter does not exactly match the number of colors available in the terminal hardware.

This parameter sets the field !D.N_COLORS, which affects the loading of color tables, the scaling used by the TVSCL procedure, and the number of bits output by

the TV procedure to the terminal. It also changes the default color, !P.COLOR to the number of colors minus one.

COPY

(WIN, X)

Use this keyword to copy a rectangular area of pixels from one region of a window to another. COPY should be set a six or seven element array: $[X_s, Y_s, N_x, N_y, X_d, Y_d, W]$, where: (X_s, Y_s) is the lower left corner of the source rectangle, (N_x, N_y) are the number of columns and rows in the rectangle, and (X_d, Y_d) is the coordinate of the destination rectangle. Optionally, W is the index of the window *from which the pixels should be copied to the current* window. If it is not supplied, the current window is used as both the source and destination.

COURIER

(PS)

Set this keyword to select the Courier PostScript font.

CURSOR_CROSSHAIR

(WIN, X)

Set this keyword to select the crosshair cursor type. This is the IDL default.

CURSOR_IMAGE

(WIN, X)

Specifies the cursor pattern. The value of this keyword must be a 16-line by 16-column bitmap, contained in a 16-element short integer vector. The offset from the upper left pixel to the point that is considered the hot spot can be provided via the CURSOR_XY keyword.

CURSOR_MASK

(WIN, X)

When the CURSOR_IMAGE keyword is used to specify a cursor bitmap, the CURSOR_MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the CURSOR_IMAGE that should be seen and bits that are not set are masked out.

By default, the `CURSOR_IMAGE` bitmap is used for both the image and the mask. This can cause the cursor to be invisible on a black background (because only black pixels are allowed to be displayed).

CURSOR_ORIGINAL

(WIN, X)

Set this keyword to select the window system's default cursor. Under X Windows, it is the cursor in use by the root window when IDL starts. For the Microsoft Windows device, it is the arrow pointer.

CURSOR_STANDARD

(WIN, X)

This keyword can be used to change the cursor appearance in IDL graphics windows.

For X Windows

This keyword selects one of the predefined cursors provided by the X Window system. The available cursors shapes are defined in the file `cursorfont.h` in the directory `/usr/include/X11`. In order to use one of these cursors, you select the number of the cursor and provide it as the value of the `CURSOR_STANDARD` keyword. For example, the file gives the value of `XC_CROSS` as being 30. In order to make that the current cursor, use the statement:

```
DEVICE, CURSOR_STANDARD=30
```

For Microsoft Windows

The table below shows the values for `CURSOR_STANDARD` that result in different cursor shapes. For example, to change the cursor to an "I-beam" when the cursor is in an IDL graphics window, use the command:

```
DEVICE, CURSOR_STANDARD = 32513
```

Value	Cursor Shape
32512	Arrow
32513	I-Beam
32514	Hourglass
32515	Black Crosshair

Table A-6: Values for the WIN device CURSOR_STANDARD Keyword

Value	Cursor Shape
32516	Up Arrow
32640	Size
32641	Icon
32642	Size NW-SE
32643	Size NE-SW

Table A-6: Values for the WIN device `CURSOR_STANDARD` Keyword

CURSOR_XY

(WIN, X)

A two element integer vector giving the (X, Y) pixel offset of the cursor hot spot, the point which is considered to be the mouse position, from the lower left corner of the cursor image. This parameter is only applicable if `CURSOR_IMAGE` is provided. The cursor image is displayed top-down—the first row is displayed at the top.

DECOMPOSED

(PS, WIN, X, Z)

Set this keyword to control how color values are interpreted when using displays with *decomposed color* (TrueColor or DirectColor visuals). This keyword has no effect on indexed-color devices, which generally specify color using 8 bits per pixel.

Set this keyword to 1 to cause color values to be interpreted as 24-bit color specifications. IDL interprets the specified value as three 8-bit color values, where the least-significant 8 bits contain the red value, the next 8 bits contain the green value,

and the most-significant 8 bits contain the blue value. For example, the following lines draw a plot in purple on a device capable of rendering 24-bit color:

```
DEVICE, DECOMPOSED=1, COLOR=1
PLOT, INDGEN(10), COLOR='FF00FF'x
```

Here, the color value 'FF00FF'x is hexadecimal notation for the RGB triple [255, 0, 255].

Note

Unlike IDL object graphics, IDL's direct graphics devices do not accept RGB triples as color specifications. Hexidecimal notation is generally the easiest way to specify 24-bit color values to direct graphics devices.

Set this keyword to 0 to cause color values to be interpreted as indices into a color lookup table. IDL interprets the least-significant 8 bits of the color value as the color table index. This setting allows users with decomposed color displays to use IDL programs written for indexed-color displays without modification.

```
DEVICE, DECOMPOSED=0, COLOR=1
LOADCT, 7
PLOT, INDGEN(10), COLOR=180
```

Here, the color value 180 is interpreted as an index into color table 7 (Red-Purple). Note that specifying `COLOR='0000B4'x` would produce the same result, since B4 is the hexadecimal notation of decimal 180.

In older versions of IDL, color index values higher than !D.N_COLORS-1 were clipped to !D.N_COLORS-1 in the higher level graphics routines. In some cases, this clipping caused the exclusive-OR graphics mode to malfunction with raster displays. This clipping has been removed. Programs that incorrectly specified color indices higher than !D.N_COLORS-1 will now probably exhibit different behavior.

The value of the DECOMPOSED keyword remains in effect until changed or until the IDL session ends. Use the [GET_DECOMPOSED](#) keyword to DEVICE to retrieve the current value.

DEMI

(PS)

Set this keyword to specify that the demi version of the current PostScript font should be used.

DIRECT_COLOR

(X)

Set this keyword to select the DirectColor visual. The value of the keyword represents the number of bits per pixel. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in “X Windows Visuals” on page 5594.

EJECT

(HP)

In order to perform an erase operation on a plotter, it is necessary to remove the current sheet of paper and load a fresh sheet. The ability of various plotters to do this varies, so the EJECT keyword allows you to specify what should be done. The following table describes the possible values.

Value	Meaning
0	Do nothing. Note that this is likely to cause one page to plot over the previous one, so you should limit yourself to one page of output per file. This is the default.
1	Use the sheet feeder to load the next page.
2	Put the plotter off-line at the beginning of each page after the first.

Table A-7: Values for the HP-GL Eject Keyword

Many HP-GL plotters lack a sheet feeder, and require the user to load the next page manually. Therefore, the default action is for IDL to not issue any page eject instructions. In this case, you must restrict yourself to generating only a single plot at a time. If your plotter has a sheet feeder, you will want to issue the command:

```
DEVICE, /EJECT
```

to tell IDL that it should use the sheet feeder instead of placing the plotter off-line.

If your plotter does not have a sheet feeder, but it does understand the HP-GL NR command, use the command:

```
DEVICE, EJECT=2
```

to place the plotter off-line at the start of every plot except the first one. This causes the plotter to wait between plots for the user to replace the paper. When the user puts the plotter back on-line, the graphics commands for the new page are executed by the plotter. Consult the programming manual for your plotter to determine if this instruction is provided.

ENCAPSULATED

(PS)

Set this keyword to create an encapsulated PostScript file, suitable for importing into another document (e.g., a LaTeX or FrameMaker document).

Note

You must explicitly set this keyword to zero to create “regular” PostScript output after creating encapsulated output. (That is, like most keyword settings to the DEVICE procedure, the setting “sticks” until you change it, or until you quit IDL.)

Note

IDL uses the value of this keyword to determine what type of output to generate when it starts writing to a file. Changing this keyword has no effect until a new file is started.

Normally, IDL assumes that its PostScript-generated output will be sent directly to a printer. It therefore includes PostScript commands to position the plot on the page and to eject the page from the printer. These commands are undesirable if the output is going to be inserted into the middle of another PostScript document. If ENCAPSULATED is present and non-zero, IDL does not generate these commands.

IDL follows the standard PostScript convention for encapsulated files. It assumes the standard PostScript scaling is in effect (72 points per inch). In addition, it declares the size, or *bounding box* of the plotting region at the top of the output file. This size is determined when the output file is opened (when the first graphics command is given), by multiplying the size of the plotting region (as specified with the XSIZE and YSIZE keywords) by the current scale factor (as specified by the SCALE_FACTOR keyword).

Changing the size of the plotting region or scale factor once graphics have been output will not be reflected in the declared bounding box, and will confuse programs that attempt to import the resulting graphics. Therefore, when generating encapsulated PostScript, do not change the plot region size or scaling factor once any graphics commands have been issued. If you need to change these parameters, use the FILENAME keyword to start a new file.

ENCODING

(CGM)

Set this keyword to set the CGM encoding type for the output file. Valid values are:

Value	Description
1	Binary encoding - the default.
2	Text encoding.
3	NCAR binary encoding.

Table A-8: CGM Encoding Values

The encoding type can only be changed when no CGM file is open.

FILENAME

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Normally, all generated output is sent to a file named `idl.xxx`, where `xxx` is the lowercase name of the device shown in the table under “[Supported Devices](#)” on page 5514. The `FILENAME` keyword can be used to change these defaults. If `FILENAME` is specified:

1. If the file is already open (as happens if plotting commands have been directed to the file since the call to `SET_PLOT`), then the file is completed and closed as if `CLOSE_FILE` had been specified.
2. The specified file is opened for subsequent graphics output.

HP-GL Only

Under UNIX, if you wish to send HP-GL output directly to a plotter without generating an intermediate file, you should specify the device special file for the plotter as the argument to `FILENAME`. For example, if your plotter is connected to a serial input/output port known on your system as `/dev/ttya`, you would issue the command:

```
DEVICE, FILENAME='/dev/ttya'
```

All subsequent HP-GL output is sent directly to the plotter connected to serial port `/dev/ttya`.

FLOYD

(PCL, X)

Set this keyword to select the Floyd-Steinberg method of dithering. This algorithm distributes the error, due to displaying intermediate shades in either black or white, to surrounding pixels. This method generally gives the most pleasing results but requires the most computer time.

FONT_INDEX

(PS)

An integer representing the font index to be mapped to the current PostScript font.

Normally the font specification keywords (AVANTGARDE, etc.) take effect immediately to change the current font. The FONT_INDEX keyword alters this behavior. The current font is not changed. Instead, the specified font is mapped to the specified font index. This mapping can then be used within text strings to change the font in the middle of the string. See [“Using PostScript Fonts”](#) on page 5576

FONT_SIZE

(PS)

The default height used for displayed text. FONT_SIZE is given in points (a common typesetting unit of measure). The default size is 12 point text.

GET_CURRENT_FONT

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the name of the current font is returned as a scalar string. A null string is returned if the Windows font is the default font. If the current device is PRINTER or METAFILE, the current font is returned.

GET_DECOMPOSED

(PS, WIN, X, Z)

Set this keyword to a named variable in which is returned the current state of the decomposed flag in the current direct graphics device.

GET_FONTNAMES

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which a string array containing the names of available fonts is returned. If no fonts are found, a null scalar string is returned. This keyword must be used in conjunction with the SET_FONT keyword. Set the SET_FONT keyword to a scalar string containing the name of the desired font or to a wildcard. For example, the following command will return in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

GET_FONTNUM

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the number of fonts available to your installation is returned. This keyword must be used in conjunction with the SET_FONT keyword. Set the SET_FONT keyword to a scalar string containing the name of the desired font or a wildcard. For example, the following command will return in the variable `numfonts` the number of available fonts:

```
DEVICE, GET_FONTNUM=numfonts, SET_FONT='*'
```

GET_GRAPHICS_FUNCTION

(WIN, X, Z)

Set this keyword to a named variable that will contain the value of the current graphics function (which is set with the SET_GRAPHICS_FUNCTION keyword). This can be used to remember the current graphics function, change it temporarily, and then restore it. See “[SET_GRAPHICS_FUNCTION](#)” on page 5550 keyword for an example.

GET_PAGE_SIZE

(PRINTER)

Set this keyword to a named variable that will contain a two-element vector that contains the width and height of the page size in pixels.

GET_PIXEL_DEPTH

(Z)

Set this keyword to a named variable that will contain the current pixel depth of the current direct graphics device.

GET_SCREEN_SIZE

(WIN, X)

Set this keyword to a named variable in which to return a two-word array that contains the width and height of the server's screen, in pixels.

GET_VISUAL_DEPTH

(WIN, X)

Set this keyword to a named variable into which a long integer is returned containing the depth of the visual associated with this device. Under X, if the X server is not connected when you call the DEVICE procedure with this keyword set, a new connection is made.

GET_VISUAL_NAME

(WIN, X)

Set this keyword equal to a named variable in which a string containing the name of the current visual class IDL is using is returned. Possible return values are:

- StaticGray (X only)
- GrayScale (X only)
- StaticColor (X only)
- PseudoColor
- TrueColor
- DirectColor (X only)

Under X, if no connection to the X server has been established when the DEVICE procedure is called with this keyword set, a new connection is made.

GET_WINDOW_POSITION

(WIN, X)

Set this keyword to a named variable that returns a two-element array containing the (X,Y) position of the lower left corner of the current window on the screen. The origin is also in the lower left corner of the screen.

GET_WRITE_MASK

(WIN, X, Z)

Specifies the name of a variable that will contain the current value of the write mask.

GIN_CHARS

(TEK)

The number of characters IDL is to read when accepting a GIN (Graphics INput) report. The default is 5. If your terminal is configured to send a carriage return at the end of each GIN report, set this parameter to 6. If the number of GIN characters is too large, the IDL CURSOR procedure will not respond until two or more keys are struck. If it is too small, the extra characters sent by the terminal will appear as input to the next IDL prompt.

GLYPH_CACHE

(METAFILE, PRINTER, PS, WIN, Z)

Set this keyword to a scalar specifying the maximum number of glyphs to cache at any given time. The first time a glyph from a TrueType font is used, it is tessellated into triangles. These triangles are cached so that the tessellation step is not repeated for each use of that glyph. If the glyph cache fills, the least used glyph will be released before a new glyph is generated and cached. The default is 256.

HELVETICA

(PS)

Set this keyword to select the Helvetica PostScript font.

INCHES

(HP, METAFILE, PCL, PRINTER, PS)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if INCHES is present and non-zero, they are taken to be in inches instead.

INDEX_COLOR

(METAFILE, PRINTER)

Set this keyword to place the printer or MetaFile device in index color mode. This is the default. This keyword is applicable only when the printer or MetaFile device is selected.

ISOLATIN1

(PS)

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters.

ITALIC

(PS)

Set this keyword to specify that the italic version of the current PostScript font should be used.

LANDSCAPE

(HP, PCL, PRINTER, PS)

IDL normally generates plots with portrait orientation (the abscissa is along the short dimension of the page). If the LANDSCAPE keyword is set, landscape orientation (abscissa along the long dimension of the page) is used instead. Note that explicitly setting LANDSCAPE=0 is the same as setting the **PORTRAIT** keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to landscape layout is started.

Note

The ability to set a printer to landscape mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

LANGUAGE_LEVEL

(PS)

Set this keyword to indicate the language level of the PostScript output that is to be generated by the device. Valid values include 1 (the default) and 2 (required for some features, such as filled patterns for polygons).

LIGHT

(PS)

Set this keyword to specify that the light version of the current PostScript font should be used.

MEDIUM

(PS)

Set this keyword to specify that the medium version of the current PostScript font should be used.

NARROW

(PS)

Set this keyword to specify that the narrow version of the current PostScript font should be used.

NCAR

(CGM)

Set this keyword to set the encoding type for the CGM output file to NCAR binary.

The NCAR Binary Encoding

The NCAR binary encoding is used exclusively by the NCAR graphics package. Version 3.01 of NCAR View (`ctrans`, `ictrans`, and `cgm2ncgm`) does not correctly handle the following graphic elements:

- Cell arrays (raster images) with an odd number of pixels in the X dimension. Solution: specify an even number of pixels for the X dimension or make the image one column wider and fill with zeros.
- Raster images drawn in top down order. Solution: invert the image prior to using `TV` or `TVSCL` and do not use the `/ORDER` keyword. For example:

```
TV, image
; Draw image top to bottom:
TV, ROTATE(image, 7)
```

OBLIQUE

(PS)

Set this keyword to specify that the oblique version of the current PostScript font should be used.

OPTIMIZE

(PCL)

It is desirable, though not always possible, to compress the size of the PCL output file. Such optimization reduces the size of the output file, and improves I/O speed to the printer. There are three levels of optimization:

Value	Description
0	No optimization is performed. This is the default because it will work with any PCL device. However, users of devices which can support optimization should use one of the other optimization levels.
1	Optimization is performed using PCL optimization primitives. This gives the best output compression and printing speed. Unfortunately, not all PCL devices support it. On those that can't, the result will be garbage printed on the page. Consult the programmers manual for your printer to determine if it supports the required escape sequences. The required sequences are: <ESC>*b0M (select full graphics mode), <ESC>*b1M (select compacted graphics mode 1), and <ESC>*b2M (select compacted graphics mode 2). The HP LaserJet II does not support this optimization level. The DeskJet PLUS does.
2	IDL attempts to optimize the output by explicitly moving the left margin and then outputting non-blank sections of the page. This is primarily intended for use with the LaserJet II, which does not support optimization level 1. Note: This optimization can be very slow on some devices (such as the DeskJet PLUS). On such devices, it is best to avoid this optimization level.

Table A-9: PCL Optimization Values

ORDERED

(PCL, X)

Set this keyword to select the ordered dither method. This introduces a pseudo-random error into the display by using a 4 by 4 “dither” matrix, yielding 16 apparent intensities. This is the default method.

OUTPUT

(HP, PS)

Specifies a scalar string that is sent directly to the graphics output file without any processing, allowing the user to send arbitrary commands to the file. Since IDL does not examine the string, it is the user's responsibility to ensure that the string is correct for the target device.

PALATINO

(PS)

Set this keyword to select the Palatino PostScript font.

PIXELS

(PCL)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if the PIXELS keyword is set, they are taken to be in pixels instead. Note that the selected resolution will determine how large a region is actually written on the page.

PLOT_TO

(REGIS, TEK)

Directs the Tektronix graphic output that would normally go to the user's terminal to the specified I/O unit. The logical unit specified should be open with write access to a device or file. Graphic output may be saved in files for later playback, redirected to other terminals, or to devices that can accept Tektronix graphic commands.

Do not use the interactive graphics cursor when graphic output is not directed to your terminal.

To direct the graphic data to both the terminal and the file, set the unit to the negative of the actual unit number. Alternatively, you can use the TTY keyword, described below.

If the specified unit number is zero then Tektronix output to the file is stopped.

PLOTTER_ON_OFF

(HP)

There are some configurations in which a HP-GL plotter is connected between the computer and a terminal. In this mode (known as eavesdrop mode), the plotter

ignores everything it is sent and passes it through to the terminal—the plotter is logically off. This state continues until an escape sequence is sent that turns the plotter logically on. At this point the plotter interprets and executes all input as HP-GL commands. Another escape sequence is sent at the end of the HP-GL commands to return the plotter to the logically off state.

Most configurations do not use eavesdrop mode, and the plotter is always logically on. However, if you are using this style of connection, you must use `PLOTTER_ON_OFF` to instruct IDL to generate the necessary on/off commands. If present and non-zero, `PLOTTER_ON_OFF` causes each output page to be bracketed by device control commands that turn the plotter logically on and off. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

POLYFILL

(HP)

Some plotters (e.g., HP7550A) can perform polygon filling in hardware, while others (e.g., HP7475) cannot. IDL therefore assumes that the plotter cannot, and generates all polygon operations in software using line drawing. Specifying a non-zero value for the `POLYFILL` keyword causes IDL to use the hardware polygon filling. Setting it to zero reverts to software filling.

Different implementations of HP-GL plotters may have different limits for the number of vertices that can be specified for a polygon region before the plotter runs out of internal memory. Since this limit can vary, the HP-GL driver cannot check for calls to `POLYFILL` that specify too many points. Therefore, it is possible for the user to produce HP-GL output that causes an error when sent to the plotter. To avoid this situation, minimize the number of points used. On the HP7550A, the limit is about 127 points. If you do generate output that exceeds the limit imposed by your plotter, you will have to break that polygon filling operation into multiple smaller operations.

PORTRAIT

(HP, PCL, PRINTER, PS)

Set the `PORTRAIT` keyword to generate plots using portrait orientation. Portrait orientation is the default. Note that explicitly setting `PORTRAIT=0` is the same as setting the `LANDSCAPE` keyword.

If the current device is `PRINTER`, and a page is open in the printer, it is closed and a new page set to portrait layout is started.

Note

The ability to set a printer to portrait mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

PRE_DEPTH

(PS)

Set this keyword to a value indicating the bit depth to be used for the preview in the PostScript file. Valid values are 1 (for black and white preview) and 8 (for 8-bit grayscale preview). This keyword applies only if the PREVIEW keyword is nonzero. The default depth is 8.

PRE_XSIZE

(PS)

Set this keyword to the width to be used for the preview in the PostScript file. PRE_XSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, [“A Note About Preview Dimensions”](#).

PRE_YSIZE

(PS)

Set this keyword to the height to be used for the preview in the PostScript file. PRE_YSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, [“A Note About Preview Dimensions”](#).

PREVIEW

(PS)

Set this keyword to 1 to add a platform-independent preview to the PostScript output file in encapsulated PostScript interchange format (EPSI). EPSI is an ASCII format. Set this keyword to 2 to write the EPS file in EPSF format, including an on-screen preview that is supported by many Windows applications, e.g. MSWord. The default (0) is to not include a preview.

Note

EPSF is not an ASCII format and cannot be sent directly to a Postscript printer, unlike the EPSI format. It must be imported into an application for printing.

A Note About Preview Dimensions

Different applications may utilize the information within a PostScript file in different ways when displaying a screen preview. Some applications will ignore the preview contents entirely, and simply use the primary PostScript contents to generate a screen preview. Other applications will use the preview data and its corresponding dimensions for screen display. Still others will use the preview data and stretch it to the dimensions of the primary PostScript contents. It is therefore recommended that the target application (into which the encapsulated PostScript file is to be loaded) be considered when selecting an appropriate XSIZE, YSIZE, PRE_XSIZE, and PRE_YSIZE.

PRINT_FILE

(WIN)

Set this keyword to the name of a file (e.g., PostScript or PCL) to be sent to the currently-selected Windows printer. IDL performs no type checking on this file before sending it to the printer. Therefore, if you have a PostScript printer selected and you send a file that contains no valid PostScript information, you'll simply get text output.

To send the file `myfile.ps` to the currently-selected Windows printer, enter:

```
DEVICE, PRINT_FILE='myfile.ps'
```

PSEUDO_COLOR

(X)

If this keyword is present, the PseudoColor visual is used. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 5594.

RESET_STRING

(TEK)

The string used to place the terminal back into the normal interactive mode after drawing graphics. Use this parameter, in conjunction with the SET_STRING keyword, to control the mode switching of your terminal.

For example, the GraphON 200 series terminals require the string <ESC>2 to activate the alphanumeric window after drawing graphics. The call to set this is:

```
DEVICE, RESET = string(27b) + '2'
```

If the 4100 series mode switch is set, using the keyword TEK4100, the default mode resetting string is <ESC>%!1, which selects the ANSI code mode.

RESOLUTION

(PCL)

PCL Only

The resolution at which the PCL printer will work. PCL supports resolutions of 75, 100, 150, and 300 dots per inch. The default is 300 dpi. Lower resolution gives smaller output files, while higher resolution gives superior quality.

RETAIN

(WIN, X)

Use this keyword to specify the default method used for backing store when creating new windows. This is the method used when the RETAIN keyword is not specified with the WINDOW procedure. Backing store is discussed in more detail under [“Backing Store”](#) on page 5559, along with the possible values for this keyword. If RETAIN is not used to specify the default method, method 1 (server-supplied backing store) is used.

The initial value of this parameter is taken from the [IDL_GR_WIN_RETAIN](#) preference (Microsoft Windows) or the [IDL_GR_X_RETAIN](#) preference (UNIX).

A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See [“Unexpected Results Using TVRD with X Windows”](#) on page 2670.

SCALE_FACTOR

(PRINTER, PS)

Specifies a scale factor applied to the entire plot. The default value is 1.0, allowing output to appear at its normal size. `SCALE_FACTOR` is used to magnify or shrink the resulting output.

The `SCALE_FACTOR` keyword behaves slightly differently in the context of the `PRINTER` device than it does in the context of the `PS` device.

When the current device is `PRINTER`, the `SCALE_FACTOR` keyword is designed to emulate a scalable resolution setting on the printer. For example, if you have a 300 x 300 pixel image—stored in the variable *image*—the following IDL commands will print *image* in a 0.5 inch square on a 600 dpi printer:

```
SET_PLOT, 'printer'
TV, image
```

Setting `SCALE_FACTOR` to 2 will scale the image to a 1 inch square on the same 600 dpi printer:

```
SET_PLOT, 'printer'
DEVICE, SCALE_FACTOR=2
TV, image
```

The output of IDL's Direct Graphics routines (`CONTOUR`, `PLOT`, `SURFACE`, etc.) is automatically scaled to fill the available drawing area. As a result, the following IDL commands will produce two identical copies of the same output on any printer:

```
SET_PLOT, 'printer'
PLOT, data
DEVICE, SCALE_FACTOR=2
PLOT, data
```

SCHOOLBOOK

(PS)

Set this keyword to select the New Century Schoolbook PostScript font.

SET_CHARACTER_SIZE

(CGM, HP, METAFILE, PCL, PRINTER, PS, REGIS, TEK, WIN, X, Z)

Set this keyword equal to a two-element vector to specify the font size and line spacing (leading) of vector and TrueType fonts, and the line spacing of device fonts. The way that the value of this vector determines character size is not completely intuitive.

The vector specified to the `SET_CHARACTER_SIZE` keyword sets the values of the `X_CH_SIZE` and `Y_CH_SIZE` fields in the `!D` structure. These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width fits in the specified rectangle. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines (baseline to baseline) is determined explicitly by the height of the rectangle.

For device fonts, the character size is fixed. When the device font system is in use, the first element of the vector specified to `SET_CHARACTER_SIZE` is silently ignored, and only the line-spacing value is used.

Note

Changing between font systems (and sometimes changing from one font to another within the same font system) can also change the `!D` structure, so do not assume that the character size you have set is preserved when you change fonts.

SET_COLORMAP

(PCL)

Set this keyword to a 14,739 ($= 3 \cdot 17^3$) element byte vector containing the RGB-to-printer color translation table for a color PCL printer. The default table is for an HP Deskjet 500C printer.

The translation table is divided into red, green, and blue planes of 4913 ($=17^3$) elements each. For a given RGB triple, the offset into each plane is calculated as follows:

$$\text{Offset} = (\text{Red}/16) * 289 + (\text{Green}/16) * 17 + (\text{Blue}/16)$$

Thus, if the RGB triple is [16,32,160], the offset into each plane is 333. The printer will use the value at element 332 of the translation table as the red value, the value at element 5245 ($=4913+332$) as the green value, and the value at element 10158 ($=9826+332$) as the blue value.

The following example shows how to scale an existing colortable for use by a PCL printer.

```

; Set the plot window to the X device:
SET_PLOT, 'X'
; Create a window:
WINDOW,0,XS=300,YS=300
; Load a color table:
LOADCT,13
; Read color table values into variables:
TVLCT,r,g,b,/GET
; Re-size color table variables:
r2=CONGRID(r,4913)
g2=CONGRID(g,4913)
b2=CONGRID(b,4913)
; Create 14,739-element color map:
colormap=[r2,g2,b2]
; Change to the PCL device:
SET_PLOT, 'PCL'
; Set file name, resolution, color, and color map:
DEVICE, FILE = 'pcl.pcl', RESOLUTION = 300, $
    /COLOR, SET_COLORMAP = colormap
; Display an image:
TVSCL,DIST(900)
; Close the device:
DEVICE,/CLOSE

```

Note

The color table used need not be one of IDL's predefined tables.

SET_COLORS

(Z)

Sets the number of pixel values, !D.N_COLORS and !D.TABLE_SIZE. This value is used by a number of IDL routines to determine the scaling of pixel data and the default drawing index. Allowable values range from 2 to 256, and the default value is 256. Use this parameter to make the Z-buffer device compatible with devices with fewer than 256 colors indices.

SET_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to a scalar string specifying the name of the font used when a hardware or TrueType font is selected. Note that hardware fonts cannot be rotated, scaled, or projected, and that the “!” commands for formatting may not work. When generating three-dimensional plots, it is best to use the vector-drawn or TrueType characters.

Note

On some platforms, GET_FONT returns an empty string. When SET_FONT is passed an empty string, the first font that can be successfully loaded will be used. This is the first available font found in the user's resource file (\$HOME/.Xdefaults) or the app-defaults file (\$IDL_DIR/resource/X11/lib/app-defaults/Idl).

Note on the FONT Keyword

The SET_FONT keyword was introduced with IDL version 5.1 and replaces the FONT and USER_FONT keywords used in previous versions.

Using TrueType Fonts

For TrueType fonts, the specified font name must exactly match one of the names in the first column of the `ttfont.map` file in the `resource/fonts/tt` directory or (on Windows platforms) the name of an installed font. See [“About TrueType Fonts”](#) on page 5732 for details on the `ttfont.map` file and for a listing of TrueType fonts distributed with IDL. Note that you must include the TT_FONT keyword to indicate that the font specified is a TrueType font. For example, the following sets the font to the font to the TrueType font Helvetica Bold Italic:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

Note

You can append additional TrueType fonts to the `ttfont.map` file if desired; on Windows platforms, additional fonts can also be added via the normal font installation procedures for your system. There is no guarantee that TrueType fonts you add will be satisfactorily tessellated or displayed. See [“About TrueType Fonts”](#) on page 5732 for details.

Using Hardware Fonts

Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. X Windows users can use the `xlsfonts` command to list available X Windows fonts.

On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

Microsoft Windows

The SET_FONT keyword should be set to a string with the following form:

```
DEVICE, SET_FONT='font*modifier1*modifier2*...modifiern'
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = 'GARAMOND*ITALIC*24'
PLOT, FINDGEN(10), TITLE = 'IDL Plot'
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

Note

If you set the output device to PostScript (SET_PLOT, 'PS'), attempting to use the (*) delimiter with SET_PLOT will cause an error. You must use SET_PLOT with specific PostScript font strings as described in [“Fonts and the PostScript Device”](#) on page 5738.

SET_GRAPHICS_FUNCTION

(WIN, X, Z)

Most window systems allow applications to specify the graphics function. This is a logical function which specifies how the source pixel values generated by a graphics operation are combined with the pixel values already present on the screen. The complete list of possible values is given in the following table:

Logical Function	Code	Definition
GXclear	0	0
GXand	1	source AND destination
GXandReverse	2	source AND (NOT destination)
GXcopy	3	source
GXandInverted	4	(NOT source) AND destination
GXnoop	5	destination
GXxor	6	source XOR destination
GXor	7	source OR destination
GXnor	8	(NOT source) AND (NOT destination)
GXequiv	9	(NOT source) XOR destination
GXinvert	10	(NOT destination)
GXorReverse	11	source OR (NOT destination)
GXcopyInverted	12	(NOT source)
GXorInverted	13	(NOT source) OR destination
GXnand	14	(NOT source) OR (NOT destination)
GXset	15	1

Table A-10: Graphic Function Codes

The default graphics function is GXcopy, which causes new pixels to completely overwrite any previous pixels. Not all functions are available on all window systems.

For example, the following code segment inverts the bottom bit in the rectangle defined by its diagonal corners (x_0, y_0) and (x_1, y_1) :

```

; Set graphics function to exclusive or (GXor), and save the
; old function:
DEVICE, GET_GRAPHICS_FUNCTION = oldg, SET_GRAPHICS_FUNCTION = 6
; Use POLYFILL to select the area to be inverted. The source
; pixel value is 1:
POLYFILL, [[x0,y0], [x0,y1], [x1,y1], [x1,y0]], $
    /DEVICE, COLOR=1
; Restore the previous graphics function:
DEVICE, SET_GRAPHICS_FUNCTION=oldg

```

SET_PIXEL_DEPTH

(Z)

Set this keyword equal to a value specifying the desired pixel depth. Allowed values are 8 (the default) and 24. IDL clears the frame and depth buffers when the value of this keyword changes.

SET_RESOLUTION

(Z)

Set this keyword to a two-element vector that specifies the width and height of the Z-buffers. The default size is 640 by 480. If this size is not the same as the existing buffers, the current buffers are destroyed and the device is reinitialized.

SET_STRING

(TEK)

The string used to place the terminal into the graphics mode from the normal interactive terminal mode. If the 4100 series mode switch is set, using the keyword TEK4100, the default graphic mode setting string is `<ESC>%!0`, which selects the Tektronix code mode.

SET_TRANSLATION

(X)

This keyword can be used to allow multiple, simultaneous IDL sessions to use the same colors from a shared colormap. Use this keyword before the X connection is established (i.e., before a window is created), IDL will use the shared color map without allocating any additional colors, and will not load a grayscale ramp as is

usually done when the X server starts up. The following example shows two cooperating IDL processes sharing the same colormap:

Execute the following commands in the first IDL session:

```
WINDOW, GET_X_ID = a
DEVICE, TRANSLATION = t
OPENW, 1, 'junk.dat'
WRITEU, 1, a, !D.N_COLORS, t[0:!D.N_COLORS-1]
CLOSE, 1
LOADCT, 3
```

Execute the following commands in the second IDL session:

```
OPENR, 1, 'junk.dat'
a=0L
n=0L
READU, 1, a, n
t = BYTARR(n)
READU, 1, t
CLOSE, 1
DEVICE, SET_TRANSLATION = t
WINDOW, COLORS=n, SET_X_ID=a
TV, DIST(256)
```

SET_WRITE_MASK

(WIN, X, Z)

Sets the write mask to the specified value. For an n -bit system, the write mask can range from 0 to 2^n-1 .

STATIC_COLOR

(X)

Use this keyword to select the X Windows StaticColor visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 5594.

STATIC_GRAY

(X)

Use this keyword to select the X Windows StaticGray visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in [“X Windows Visuals”](#) on page 5594.

SYMBOL

(PS)

Set this keyword to select the Symbol PostScript font.

TEK4014

(TEK)

Set this keyword to specify that coordinates are to be output with full 12-bit resolution. If this keyword is not present or is zero, 10-bit coordinates are output. Normally, IDL sends 10-bit coordinates. 12-bit coordinates are compatible with most terminals, even those without the full resolution, but require more characters to send.

Note

The 4014 and the 4100 modes can be used together. The coordinate system IDL uses for the Tektronix is 0 to 4095 in the X direction and 0 to 3120 in the Y direction, even when not in the 4014 mode. In the 10-bit case the internal coordinates are divided by 4 prior to output.

TEK4100

(TEK)

Set this keyword to indicate that the terminal is a 4100 or 4200 series terminal. The use of color, ANSI and Tektronix mode switching, hardware line styles, and pixel output with the TV procedure is supported with these terminals. Also, text is output differently.

TEXT

(CGM)

Set this keyword to set the encoding type for the CGM output file to text.

THRESHOLD

(PCL, X)

Set this keyword to select the threshold algorithm—the simplest dithering method. The value of this keyword is the threshold to be used. This algorithm simply compares each pixel against the given threshold, usually 128. If the pixel equals or exceeds the threshold the display pixel is set to white, otherwise it is black.

TIMES

(PS)

Set this keyword to select the Times-Roman PostScript font.

TRANSLATION

(WIN, X)

As discussed in “[Shared Colormaps](#)” on page 5597, using the shared colormap (normally recommended) causes IDL to translate between IDL color indices (which always start with zero and are contiguous) and the pixel values actually present in the display. The TRANSLATION keyword specifies the name of a variable to receive the translation vector. To read the translation table, use the command:

```
DEVICE, TRANSLATION=TRANSARR
```

where TRANSARR is a named variable into which the translation array is stored. The result is a 256-element byte vector. Element zero of the vector contains the pixel value allocated for the first color in the IDL colormap, and so forth.

Microsoft Windows Only

This keyword is accepted by the WIN device, for compatibility with the X Windows driver, but simply returns a 256-element vector where each element has the value of its subscript (0 to 255).

TRUE_COLOR

(METAFILE, PRINTER, X)

Use this keyword to select TrueColor visuals for the output device.

For the METAFILE and PRINTER Devices:

Set this keyword to a value greater than zero to place the output device in in RGB or 24-bit TrueColor mode. The number of bits per pixel specified is ignored.

For the X Device:

Set this keyword equal to the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes for the X Windows device are discussed in more detail in “[X Windows Visuals](#)” on page 5594.

TT_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to indicate that the font set via the `SET_FONT` keyword (either to set the fontname or to retrieve fontnames in conjunction with the `GET_FONTNAMES` or `GET_FONTNUM` keywords) should be treated as a TrueType font.

TTY

(REGIS, TEK)

Set this keyword to specify that output should be sent to the terminal at the same time that it is being sent to a file due to the `FILENAME` or `PLOT_TO` keywords. A zero value causes output to go only to the file. If no output file is in use, this keyword has no effect.

USER_FONT

(PS)

This keyword is now obsolete and has been replaced by the `SET_FONT` keyword. Code that uses the `USER_FONT` keyword will continue to function as before, but we suggest that all new code use `SET_FONT`.

VT240

VT241

(REGIS)

Set this keyword to configure the REGIS device for VT240 series terminals.

VT340

VT341

(REGIS)

Set this keyword to configure the REGIS device for VT340 series terminals.

WINDOW_STATE

(WIN, X)

Set this keyword to a named variable that returns an array containing one element for each possible window. Array element i contains a 1 if window i is open, otherwise it contains a 0.

XOFFSET

(HP, PCL, PRINTER, PS)

Specifies the X position, on the page, of the lower left corner of output generated by IDL. XOFFSET is specified in centimeters, unless INCHES is specified. See [“Positioning Graphics Output”](#) on page 5564.

PostScript Only

SCALE does not affect the value of XOFFSET.

XON_XOFF

(HP)

If present and non-zero, XON_XOFF causes each output page to start with device control commands that instruct the plotter to obey xon/xoff (^S/^Q) style flow control. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

Such handshaking is the default. To turn it off, use the command

```
DEVICE, XON_XOFF=0
```

Often, it is not necessary to tell the plotter to obey flow control because the printing facilities on the system handle such details for you, but it is usually harmless.

XSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the width of output generated by IDL. XSIZE is specified in centimeters, unless INCHES is specified.

Note

For PCL and PS devices, this keyword’s value is effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

PostScript Only

SCALE modifies the value of XSIZE. Hence, the following statement:

```
DEVICE, /INCHES, XSIZE=7.0, SCALE_FACTOR=0.5
```

results in a real width of 3.5 inches.

Also see [“A Note About Preview Dimensions”](#) on page 5543.

YOFFSET

(HP, PCL, PRINTER, PS)

Specifies the Y position, on the page, of the lower left corner of output generated by IDL. YOFFSET is specified in centimeters, unless INCHES is specified. See [“Positioning Graphics Output”](#) on page 5564.

Note

The corner of the page from which the Y offset is measured (lower or upper left) differs on various devices. Read the device specific information in the following sections to determine how this is handled for your device.

PostScript Only

SCALE does not affect the value of YOFFSET.

YSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the height of output generated by IDL. YSIZE is specified in centimeters, unless INCHES is specified.

Note

For PCL and PS devices, this keyword’s value is effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

PostScript Only

SCALE modifies the value of YSIZE. Hence, the following statement:

```
DEVICE, /INCHES, YSIZE=5.0, SCALE_FACTOR=0.5
```

results in a real width of 2.5 inches.

Also see [“A Note About Preview Dimensions”](#) on page 5543.

ZAPFCHANCERY

(PS)

Set this keyword to select the ITC Zapf Chancery PostScript font.

ZAPFDINGBATS

(PS)

Set this keyword to select the ITC Zapf Dingbats PostScript font.

Z_BUFFERING

(Z)

This keyword enables and disables the Z-buffering. If this keyword is specified with a zero value, the driver operates as a standard 2-D device, the Z-buffering is disabled, and the Z-buffer (if any) is deallocated. Setting this keyword to one (the default value), enables the Z-buffering.

To disable Z-buffering enter:

```
DEVICE, Z_BUFFERING = 0
```

Window Systems

The different window systems supported by IDL have many features in common. This section describes those features. See the individual descriptions of each system later in this chapter for additional information about each one.

IDL utilizes the window system by creating and using one or more largely independent windows, each of which can be used for the display of graphics and/or images. One color map table is shared among all these windows. Multiple windows can be active simultaneously. Windows are referenced using their index which is a non-negative integer.

“Dithering” or halftoning techniques are used to display images with multiple shades of gray on monochrome displays—displays that can only display white or black. This topic is discussed in [“Image Display On Monochrome Devices”](#) on page 5561.

Graphic and image output is always directed to the current window. When a window system is selected as the current IDL graphics device, the index number of the current window is found in the `!D.WINDOW` system variable. This variable contains -1 if no window is open or selected. The `WSET` procedure is used to change the current window. `WSHOW` hides, displays, and iconifies windows. `WDELETE` deletes a window.

The `WINDOW` procedure creates a new window with a given index. If a window already exists with the same index, it is first deleted. The size, position, title, and number of colors, may also be specified. If you access the display before creating the first window, IDL automatically creates a window with an index number of 0 and with the default attributes.

Backing Store

One of the features that distinguishes various window systems is how they handle the issue of backing store. When part of a window that was previously not visible is exposed, there are two basic approaches that a window system can take. Some keep track of the current contents of all windows and automatically repair any damage to their visible regions (retained windows). This saved information is known as the backing store. Others simply report the damage to the program that created the

window and leave repairing the visible region to the program (non-retained windows).

Value	Description
0	No backing store.
1	Request the server or window system to perform backing store.
2	Make IDL perform backing store.

Table A-11: Allowed Values for the RETAIN Keyword

There are convincing arguments for and against both approaches. It is generally more convenient for IDL if the window system handles this problem automatically, but this often comes at a performance penalty. The actual cost of retained windows varies between systems and depends partially on the application.

The X Window system does not by default keep track of window contents. Therefore, when a window on the display is obscured by another window, the contents of its obscured portion is lost. Re-exposing the window causes the X server to fill the missing data with the default background color for that window, and request the application to redraw the missing data. Applications can request a backing store for their windows, but servers are not required to provide it. Many X servers do not provide backing store, and even those that do cannot necessarily provide it for all requesting windows. Therefore, requesting backing store from the server might help, but there is no certainty.

The IDL window system drivers allow you to control the issue of backing store using the RETAIN keyword to the DEVICE and WINDOW procedures. Using it with DEVICE allows you to set the default action for all windows, while using it with WINDOW lets you override the default for the new window. The possible values for this keyword are summarized under “[Backing Store](#)” on page 5559, and are described below:

- Setting the RETAIN keyword to 0 specifies that no backing store is kept. In this case, exposing a previously obscured window leaves the missing portion of the window blank. Although this behavior can be inconvenient, it usually has the highest performance because there is no need to keep a copy of the window contents.
- Setting the RETAIN keyword to 1 causes IDL to request that a backing store be maintained. If the window system decides to accept the request, it will automatically repair the missing portions when the window is exposed. X

Windows may or may not provide backing store when requested, depending on the capabilities of the server and the resources available to it.

- Setting the RETAIN keyword to 2 specifies that IDL should keep a backing store for the window itself, and repair any window damage when the window system requests it. This option exists for X Windows. In this case, a pixmap (off-screen display memory) the same size as the window is created at the same time the window is created, and all graphics operations sent to the window are also sent to the pixmap. When the server requests IDL to repair freshly exposed windows, this pixmap is used to fill in the missing contents. Pixmap is a precious resource in the X server, so backing pixmaps should only be requested for windows with contents that must absolutely be preserved.

If the type of backing store to use is not explicitly specified using the RETAIN keyword, IDL assumes option 1 and requests the window system to keep a backing store.

A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See [“Unexpected Results Using TVRD with X Windows”](#) on page 2670.

Image Display On Monochrome Devices

Images are automatically dithered when sent to some monochrome devices. Dithering is a technique which increases the number of apparent brightness levels at the expense of spatial resolution. Images with 256 gray levels are displayed on a display with only two colors, black and white, using halftoning techniques. PostScript handles dithering directly. IDL supports dithering for other devices if their DEVICE procedures accept the FLOYD, ORDERED, or THRESHOLD keywords.

Printing Graphics Output Files

For Direct Graphics printer and plotter devices (e.g., PCL, PostScript, and HP-GL), IDL creates a file containing output commands. This file can be sent to the printer via the normal methods provided by the local operating system. When attempting to output the file before exiting IDL, the user must be sure that the graphics output file is complete. For example, the following IDL commands (executed under UNIX) will not produce the desired result:

```
SET_PLOT, 'PS'
PLOT, x, y
SPAWN, 'lpr idl.ps'
```

These commands fail because the attempt to print the file is premature—the file is still open within IDL and is not yet complete.

Note

Use of SET_PLOT and the direct graphics commands is not required when creating graphical output files or printing to a printer using the iTools or other object-graphics routines.

The following lines of code are an IDL procedure called OUTPUT_PLOT which closes the current graphics file and sends it to the printer. This routine assumes that the graphics output file is named `idl.xxx`, where `xxx` represents the name of the graphics driver. For example, PostScript output file is assumed to be `idl.ps`. It also assumes that the graphics output to be printed is from the current graphics device, as selected with SET_PLOT.

```
; Close the current graphics file, and print it. If the
; New_file parameter is present, rename the file to the given
; name so it won't be overwritten:
Pro OUTPUT_PLOT, New_file
; Close current graphics file:
DEVICE, /CLOSE
; Build the default output file name by using the idl name for
; the current device (!D.NAME):
file = 'idl.' + STRLOWCASE(!D.NAME)
; Build shell commands to send file to the printer.
; You will probably have to change this command in accordance
; with local usage:
cmd = 'lpr ' + file
; Concatenate rename command if new file specified:
IF N_ELEMENTS(New_file) GT 0 THEN $
  cmd = cmd + '; mv' + file + ' ' + New_file
; Issue shell commands to print/rename file:
```

```
SPAWN, cmd  
END
```

The call to `DEVICE` causes IDL to finish the file and close it, which makes it available for printing.

Setting Up The Printer

In order for IDL generated output files to work properly with printers and plotters, it is necessary for the device to be configured properly. This usually involves configuring both the device hardware and the operating system printing software.

When setting up your system, keep the following points in mind:

- The device and computer must use some form of flow control to prevent the computer from sending data faster than the printing device can handle it. The most common form of flow control is known as XON/XOFF, and involves the sending of Control-S (off) and Control-Q (on) characters from the device to the printer to manage the flow of data.

Many printers have a large buffer into which they store incoming data they haven't yet processed. This reduces the need to invoke flow control. When testing your configuration to ensure flow control is actually enabled, you must be sure to print a document long enough to fill any such buffer, or flow control may never occur, giving a false impression that the setup is correct. A common source of problems stem from attempting to print long IDL generated output files without proper flow control.

- Some devices (such as PCL) require an eight-bit data path, while others (such as PostScript) do not. For devices that do, it is important to ensure that the printer port and system printing software provide such a connection.

If you are having problems printing on a PostScript printer, the `ehandler.ps` file in the `resource/fonts/ps` subdirectory of the IDL distribution can help you to debug your problem. Sending this file to your PostScript Printer causes it to print any subsequent errors it encounters on a sheet of paper and eject it. The effect of this file lasts until the printer is reset.

Setting Up Printers Under UNIX

Printers are configured in the `/etc/printcap` file. This file describes to the system which printers are connected to it, the characteristics of each printer, and how the printer port should be configured. Managing the `printcap` file is usually discussed in the system management documentation supplied with the system by the manufacturer.

Positioning Graphics Output

The difference between the XOFFSET and YOFFSET keywords to the DEVICE procedure, and the higher level plot positioning keywords and system variables (discussed in [Appendix B, “Graphics Keywords”](#)) can lead to confusion. A common misunderstanding is to attempt to use the DEVICE procedure “offset” and “size” keywords multiple times in an attempt to produce multiple plots on a single output page.

The DEVICE keywords are intended to specify the size and position of the entire output area on the page, not to move the plotting region for multiple plots. The driver does not monitor their values continuously, but only when initializing a new page or ejecting the current one.

The proper way to produce multiple plots is to use the high level positioning abilities. The !P.MULTI, !P.POSITION, and !P.REGION system variables can be used to position individual plots on the page. The plotting routines also accept the POSITION, MARGIN and REGION keywords.

Image Background Color

Graphical output that is displayed with a black background on a monitor frequently look better if the background is changed to white when printed on white paper. This is easily done using the **BACKGROUND** graphics keyword or (if the only values displayed in black are in the background) with a statement like:

```
a(WHERE(a EQ 0B)) = 255B
```

The CGM Device

Device Keywords Accepted by the CGM Device:

`BINARY`, `CLOSE_FILE`, `COLORS`, `ENCODING`, `FILENAME`, `NCAR`,
`SET_CHARACTER_SIZE`, `TEXT`

The CGM, Computer Graphics Metafile, standard describes a device independent file format used for the exchange of graphic information. The IDL CGM driver produces CGM files encoded in one of three methods: *Text*, *Binary* or *NCAR Binary*. To direct graphics output to a CGM file, issue the command:

```
SET_PLOT, 'CGM'
```

This causes IDL to use the CGM driver for producing graphical output. Once the CGM driver is selected, the `DEVICE` procedure controls its actions, as described below. Typing `HELP, /DEVICE` displays the current state of the CGM driver. The CGM driver defaults to the binary encoding using 256 colors.

Abilities and Limitations

This section describes details specific to IDL's CGM implementation:

- IDL uses the CGM default integer encoding for graphic primitives. Coordinate values range from 0 to 32767. It is advisable to use the values stored in `!D.X_SIZE` and `!D.Y_SIZE` instead of assuming a fixed coordinate range.
- Color information is output with a resolution of 8 bits (color indices and intensity values range from 0 to 255).
- The definition of background color in the CGM standard is somewhat ambiguous. According to the standard, color index 0 and the background color are the same. Because background color is specified in the metafile as a color value (RGB triple), not an index, it is possible to have the background color not correspond with the color value of index 0.
- The CGM `BACKGROUND_COLOUR` attribute is explicitly set by IDL only during an erase operation: changing the value of the color map at index 0 does not cause IDL to generate a `BACKGROUND_COLOUR` attribute until the next `ERASE` occurs. An `ERASE` command sets the background color to the value in the color map at index 0. The command `ERASE, INDEX` (where `INDEX` is not 0) generates the message "Value of background color is out of allowed range." For consistent results, modify the color table before any graphics are output.

- The CGM standard uses scalable (variable size) pixels for raster images. By default, the TV and TVSCL procedures output images, regardless of size, using the entire graphics output area. To output an image smaller than the graphics output area, specify the XSIZE and YSIZE keywords with the TV and TVSCL procedures. For example:

```
; Select the CGM driver:
SET_PLOT, 'CGM'
; Create a 64 x 64 element array:
X = DIST(64)
; Display the image (fills entire screen):
TVSCL, X
; Now display 4 images on the screen:
ERASE
XS = !D.X_SIZE / 2 ; Size of each image, X dimension
YS = !D.Y_SIZE / 2 ; Size of each image, Y dimension
TVSCL, X, 0, XSIZE=XS, YSIZE=YS ; Upper left
TVSCL, X, 1, XSIZE=XS, YSIZE=YS ; Upper right
TVSCL, X, 2, XSIZE=XS, YSIZE=YS ; Lower left
TVSCL, X, 3, XSIZE=XS, YSIZE=YS ; Lower right
```

The HP-GL Device

Device Keywords Accepted by the HP-GL Device:

`CLOSE_FILE`, `EJECT`, `FILENAME`, `INCHES`, `LANDSCAPE`, `OUTPUT`,
`PLOTTER_ON_OFF`, `POLYFILL`, `PORTRAIT`, `SET_CHARACTER_SIZE`,
`XOFFSET`, `XON_XOFF`, `XSIZE`, `YOFFSET`, `YSIZE`

HP-GL (Hewlett-Packard Graphics Language) is a plotter control language used to produce graphics on a wide family of pen plotters. To use HP-GL as the current graphics device, issue the IDL command:

```
SET_PLOT, 'HP'
```

This causes IDL to use HP-GL for producing graphical output. Once the HP-GL driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, as described below. The default settings for the HP-GL driver are shown in the following table. Use the statement:

```
HELP, /DEVICE
```

to view the current state of the HP-GL driver.

Feature	Value
File	idl.hp
Orientation	Portrait
Erase	No action
Polygon filling	Software
Turn plotter logically on/off	No
Specify xon/xoff flow control	Yes
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.

Table A-12: Default HP-GL Driver Settings

Abilities And Limitations

IDL is able to produce a wide variety of graphical output using HP-GL. The following is a list of what is and is not supported:

- All types of vector graphics can be generated, including line plots, contours, surfaces, etc.
- HP-GL plotters can draw lines in different colors selected from the pen carousel. It should be noted that color tables are not used with HP-GL. Instead, each color index refers directly to one of the pens in the carousel.
- Some HP-GL plotters can do polygon filling in hardware. Others can rely on the software polygon filling provided by IDL.
- It is possible to generate graphics using the hardware generated text characters, although such characters do not give much improvement over the standard vector fonts. To use hardware characters, set the !P.FONT system variable to zero, or set the FONT keyword to the plotting routines to zero.
- Since HP-GL is designed to drive pen plotters, it does not support the output of raster images. Therefore, TV and TVSCL do not work with HP-GL.
- Since pen plotters are not interactive devices, they cannot support such operations as cursors and windows.

HP-GL Linestyles

The LINSTYLE graphics keyword allows specifying any of 6 linestyles. HP-GL does not support all of these linestyles, and styles 3 and 4 differ from the definition in [Appendix B, “Graphics Keywords”](#). The following table summarizes the differences:

Index	Normal Line Style	HP-GL Line Style
0	Solid	same
1	Dotted	same
2	Dashed	same
3	Dash Dot	Relative size of dash and dot are different.
4	Dash Dot Dot Dot	Dash Dot Dot
5	Long Dashes	same

Table A-13: Linestyles for the HP-GL Device

The Metafile Display Device

Device Keywords Accepted by the Metafile Device:

`CLOSE_FILE`, `FILENAME`, `GET_CURRENT_FONT`, `GET_FONTNAMES`, `GET_FONTNUM`, `GLYPH_CACHE`, `INCHES`, `INDEX_COLOR`, `SET_CHARACTER_SIZE`, `SET_FONT`, `TRUE_COLOR`, `TT_FONT`, `XSIZE`, `YSIZE`

The Windows Metafile Format (WMF) is used by Windows to store vector graphics in order to exchange graphics information between applications. This format is only available on the Windows platforms. To direct graphics to a file in the WMF format, use the `SET_PLOT` procedure:

```
SET_PLOT, 'METAFILE'
```

This causes IDL to use the Metafile driver for producing graphical output. Once the Metafile driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions. The default settings are given in the following table:

Feature	Value
File	idl.emf
Mode	N/A
Horizontal offset	N/A
Vertical offset	N/A
Width	7 in.
Height	5 in.
Resolution	Screen

Table A-14: Default Metafile Driver Settings

For example, the following will create a WMF file for a simple plot:

```
;Create X and Y Axis data
x=findgen(10)
y=findgen(10)

;Save current device name
mydevice=!D.NAME
```

```
;Set the device to Metafile
SET_PLOT, 'METAFILE'

;Name the file to be created
DEVICE, FILE='test.emf'

;Create the plot
PLOT, x, y

;Close the device which creates the Metafile
DEVICE, /CLOSE

;Set the device back to the original
SET_PLOT, mydevice
```

The Null Display Device

Device Keywords Accepted by the Null Device:

No keywords are accepted by the DEVICE procedure when the NULL device is selected.

To suppress graphics output entirely, use the null device:

```
SET_PLOT, 'NULL'
```

The PCL Device

Device Keywords Accepted by the PCL Device:

CLOSE_FILE, COLOR, FILENAME, FLOYD, INCHES, LANDSCAPE, OPTIMIZE, ORDERED, PIXELS, PORTRAIT, RESOLUTION, SET_CHARACTER_SIZE, SET_COLORMAP, THRESHOLD, XOFFSET, XSIZE, YOFFSET, YSIZE

PCL (Printer Control Language) is used by Hewlett-Packard laser and ink jet printers to produce graphics output. To direct graphics output to a PCL file, issue the command:

```
SET_PLOT, 'PCL'
```

This causes IDL to use the PCL driver for producing graphical output. Once the PCL driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings for the PCL driver are listed in the following table:

Feature	Value
File	idl.pcl
Mode	Portrait
Optimization level	0 (None)
Dither method	Floyd-Steinberg
Resolution	300 dpi
Horizontal offset	1/2 in.
Vertical offset	1 in.
Width	7 in.
Height	5 in.

Table A-15: Default PCL Driver Settings

The PCL device draws into a memory buffer of the specified size (or the default size, if the XSIZE and YSIZE keywords to DEVICE are not specified). Anything drawn outside this buffer will be silently discarded.

Note

Unlike monitors where white is the most visible color, PCL writes black on white paper. Setting the output color index to 0, the default when PCL output is selected, writes in black. A color index of 255 writes white which is invisible on white paper.

Color tables are not used with PCL unless the color mode has been enabled using the **COLOR** keyword to the **DEVICE** procedure. For images, color dithering produces realistic color image output even though PCL printers only produce eight output colors. In most cases, simply choosing an appropriate color table (using **LOADCT** or **XLOADCT**), or creating a color table from an image (via **TVLCT**) will work fine. If you need finer control over the colors used, see the **SET_COLORMAP** keyword for additional information. For vector graphics, only eight colors are supported—no line dithering is implemented. Any RGB component that is not zero is treated as 255. The correct RGB definitions for each color are shown in the following table. Use the **HELP, /DEVICE** command to view the current options for PCL output.

Color	Red Value	Green Value	Blue Value
Red	255	0	0
Green	0	255	0
Blue	0	0	255
Cyan	0	255	255
Magenta	255	0	255
Yellow	255	255	0
Black	0	0	0
White	255	255	255

Table A-16: PCL RGB Color Definitions

Note

The values of **XSIZE** and **YSIZE** for this device are effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

The Printer Device

Device Keywords Accepted by the PRINTER Device:

`CLOSE_DOCUMENT`, `GET_CURRENT_FONT`, `GET_FONTNAMES`,
`GET_FONTNUM`, `GET_PAGE_SIZE`, `INDEX_COLOR`, `PORTRAIT`,
`SCALE_FACTOR`, `SET_CHARACTER_SIZE`, `TRUE_COLOR`, `XOFFSET`,
`XSIZE`, `YOFFSET`, `YSIZE`

The PRINTER device allows IDL Direct Graphics to be output to a system printer. To direct graphics output to a printer, issue the command:

```
SET_PLOT, 'printer'
```

This causes IDL to use a printer driver to produce graphical output. By default, the default system printer is used for output. Use the `DIALOG_PRINTERSETUP` function to define the printing parameters for the printer device. Use the `DIALOG_PRINTJOB` function to control the print job itself.

Note that the printer device is an IDL Direct Graphics device. Like other Direct Graphics devices, you must change to the new device and then issue the IDL commands that send output to that device. With the printer device, you must use the `CLOSE_DOCUMENT` keyword to the `DEVICE` routine to actually initiate the print job and make something come out of your printer.

The PostScript Device

Device Keywords Accepted by the PS Device:

AVANTGARDE, BITS_PER_PIXEL, BKMAN, BOLD, BOOK, CLOSE_FILE, CMYK, COLOR, COURIER, DECOMPOSED, DEMI, ENCAPSULATED, FILENAME, FONT_INDEX, FONT_SIZE, HELVETICA, INCHES, ISOLATIN1, ITALIC, LANDSCAPE, LIGHT, MEDIUM, NARROW, OBLIQUE, OUTPUT, PALATINO, PORTRAIT, PRE_DEPTH, PRE_XSIZE, PRE_YSIZE, PREVIEW, SCALE_FACTOR, SCHOOLBOOK, SET_CHARACTER_SIZE, SET_FONT, SYMBOL, TIMES, TT_FONT, XOFFSET, XSIZE, YOFFSET, YSIZE, ZAPFCHANCERY, ZAPFDINGBATS

PostScript is a programming language designed to convey a description of a page containing text and graphics. Many laser printers and high-resolution, high-quality photo typesetters support PostScript. Color output or direct color separations can be produced with color PostScript. To direct graphics output to a PostScript file, issue the command:

```
SET_PLOT, 'PS'
```

This causes IDL to use the PostScript driver for producing graphical output. Once the PostScript driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings are given in the following table:

Feature	Value
File	idl.ps
Mode	Portrait, non-encapsulated, no color
Horizontal offset	3/4 in.
Vertical offset	5 in.
Width	7 in.
Height	5 in.
Scale factor	1.0
Font size	12 points

Table A-17: Default PostScript Driver Settings

Feature	Value
Font	Helvetica
# Bits / Image Pixel	4

Table A-17: Default PostScript Driver Settings (Continued)

Note

Unlike monitors where white is the most visible color, PostScript writes black on white paper. Setting the output color index to 0, the default when PostScript output is selected, writes black. A color index of 255 writes white which is invisible on white paper. Color tables are not used with PostScript unless the color mode has been enabled using the DEVICE procedure. See “[Indexed Color Images](#)” on page 5577

To obtain adequate resolution, the device coordinate system used for PostScript output is expressed in units of 0.001 centimeter (i.e., 1000 pixels/cm).

Use the HELP, /DEVICE call to view the current font, file, and other options set for PostScript output.

Using PostScript Fonts

Information necessary for rendering a set of 35 standard PostScript fonts are included with IDL. (The standard 35 fonts are the fonts found on the Apple Laserwriter II PostScript printer; the same fonts are found on almost any PostScript printer made in the time since the LaserWriter II appeared.) Use of PostScript fonts is discussed in detail in “[About Device Fonts](#)” on page 5736.

Color PostScript

If you have a color PostScript device you can enable the use of either indexed color or TrueColor for plotting.

Indexed Color Plots

Set the PostScript device to use indexed color with the statement:

```
DEVICE, DECOMPOSED=0, COLOR=1
```

In indexed color mode, color values are interpreted as indices into IDL’s current color table. For example, to draw a plot using the color specified by color index 160, use a statement like:

```
PLOT, INDGEN(10), COLOR = 160
```

TrueColor Plots

Set the PostScript device to use 24-bit color (often referred to as TrueColor) with the statement:

```
DEVICE, DECOMPOSED=1, COLOR=1
```

In Decomposed color mode, 24-bit color specifications are interpreted as three 8-bit color values, where the least-significant 8 bits contain the red value, the next 8 bits contain the green value, and the most-significant 8 bits contain the blue value. 24-bit color values are most commonly specified using hexadecimal notation, in which the blue, green, and red values are encoded in a string with the following format:

```
'bbgrr'x
```

where *bb* is a hexadecimal number specifying the blue value, *gg* is a hexadecimal number specifying the green value, and *rr* is a hexadecimal number specifying the red value.

For example, to draw a plot using pure blue on a device that uses 24-bit color, use the following statement:

```
PLOT, INDGEN(10), COLOR = 'FF0000'x
```

Indexed Color Images

Set the PostScript device to use color with the statement:

```
DEVICE, COLOR=1, BITS_PER_PIXEL=n
```

where the value of the `BITS_PER_PIXEL` keyword can be 1, 2, 4, or 8 bits, yielding 2, 4, 16, or 256 possible colors. In an indexed color image, each pixel value is used as an index into the current color table, thereby obtaining an RGB value for each possible pixel value. To allow pixels in the image to map to a full 256-entry color table, specify `BITS_PER_PIXEL=8`.

Note

In the case of indexed color images of fewer than 8 bits, the number of columns in the image should be an exact multiple of the number of pixels per byte (i.e., when displaying 4 bit images the number of columns should be even, and 2 bit images should have a column size that is a multiple of 4). If the image column size is not an exact multiple, extra pixels with a value of 255 are output at the end of each row. This causes no problems if the color white is loaded into the last color table entry, otherwise a stripe of the last (index 255) color is drawn to the right of the image.

TrueColor Images

Set the PostScript device to use color with the statement:

```
DEVICE, COLOR=1, BITS_PER_PIXEL=8
```

A TrueColor image consists of an array with three dimensions, one of which has a size of three, containing the three color components. It may be considered as three two dimensional images, one each for the red, green and blue components. Each two-dimensional channel uses eight bits per pixel, which combine to create the 24-bit (TrueColor) image.

Use the TRUE keyword to the TV and TVSCL procedures to indicate that the image is a TrueColor image and to specify the dimension over which color is interleaved. RGB data can be interleaved by pixel, by line, or by image. Use the TRUE keyword to specify the method of interleaving. A c column by l line TrueColor image is dimensioned as follows:

TRUE Value	Dimensions	Interleaving
1	$(3, c, l)$	Pixel
2	$(c, 3, 1)$	Line or Row
3	$(c, l, 3)$	Image

Table A-18: Values for the TRUE Keyword to TV and TVSCL

The following example writes a 24-bit image, interleaved over the first dimension, to a PostScript file:

```
; Save the original graphics device.
old_device = !D.NAME

; Change to the PostScript device.
SET_PLOT, 'PS'

; Specify an output filename.
outfile = DIALOG_PICKFILE(FILE='24bit.ps', /WRITE, $
    PATH=GETENV('IDL_TMPDIR'))

; Set the PostScript device to create the output file in
; color. Use *8* bits per pixel, not 24.
DEVICE, FILE=outfile, /COLOR, BITS_PER_PIXEL=8

; Get some truecolor image data.
image = READ_IMAGE(FILEPATH('rose.jpg', SUBDIRECTORY=['examples',
    'data']))
```

```

; Write the 24-bit image and close the file.
TV, image, TRUE=1
DEVICE, /CLOSE

; Return plotting to the original graphics device:
SET_PLOT, old_device

```

Unlike TrueColor plots using the DECOMPOSED keyword, TrueColor images are routed through IDL's color tables. The red color table array contains the intensity translation table for the red image, and so forth. Assuming that the color tables have been loaded with the vectors R , G , and B , a pixel with a color value of (r, g, b) is displayed with a color of (R_r, G_g, B_b) . As with other devices, a color table value of 255 represents maximum intensity, while 0 indicates an absence of the color. To pass the RGB pixel values without change, load the red, green and blue color tables with a ramp with a slope of 1.0:

```
TVLCT, INDGEN(256), INDGEN(256), INDGEN(256)
```

or with the LOADCT procedure:

```

; Load standard black/white table:
LOADCT, 0

```

Image Background Color

Images that are displayed with a black background on a monitor frequently look better if the background is changed to white when displayed with PostScript. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

CMYK Output

When the CMYK keyword is set, IDL converts the PostScript output to the CMYK color model as a final step. The indexed or RGB data is mapped to the cyan, magenta, yellow, and black color model just prior to output.

The CMYK format is a subtractive color model that is better suited for color printing. This color model allows some document processing applications and printer control software to easily adjust the overall brightness of an image by manipulating a single channel (K). PostScript files created with the CMYK color model must be processed by an interpreter capable of interpreting PostScript Language Level 2 or higher.

PostScript Positioning

Using the XOFFSET and YOFFSET Keywords

Often, IDL users are confused by the use of the XOFFSET and YOFFSET keywords to the PostScript DEVICE routine. These keywords control the position of IDL plots on the page. XOFFSET specifies the “X” position of the lower left corner of the output generated by IDL. This offset is always taken relative to the lower left-hand corner of the page when viewed in portrait orientation. YOFFSET specifies the “Y” position of the lower left corner of the output generated by IDL. This offset is also taken relative to the lower left-hand corner of the page when viewed in portrait orientation.

The following figure shows how the XOFFSET and YOFFSET keywords are interpreted by the PostScript device in the Portrait (left) and Landscape (right) modes. Note that the landscape plot uses the same origin for determining the effect of the XOFFSET and YOFFSET keywords, but that the output is rotated 270 degrees clockwise.

Figure A-1: Interpretation of the XOFFSET and YOFFSET Keywords

The page on the left shows an IDL plot printed in “portrait” orientation. Note that the X and Y offsets work just as we expect them to—increasing the XOFFSET moves the plot to the right and increasing the YOFFSET moves the plot up the page. The page on the right shows an IDL plot printed in “landscape” orientation. Here, the X and Y offsets are still taken relative to the same points even though the orientation of the

plot has changed. This happens because IDL moves the origin of the plot *before* rotating the PostScript coordinate system 270 degrees clockwise for the landscape plot.

Note

The XOFFSET and YOFFSET keywords have no effect when you generate ENCAPSULATED PostScript output.

Encapsulated PostScript Output

Another form of PostScript output is Encapsulated PostScript. This is the format used to import PostScript files into page layout and desktop publishing programs. An Encapsulated PostScript (EPS) file is similar to a regular PostScript file except that it contains only one page of PostScript output contained in a “bounding box” that is used to tell other programs about the size and aspect ratio of the encapsulated image.

Most of the time, output from IDL to an EPS file is properly scaled into the EPS bounding box because commands such as PLOT take full advantage of the plotting area made available to them. Sometimes, however, the default bounding box is inappropriate for the image being displayed.

As an example, suppose you have an image that is narrow and tall that, when TV’ed to an IDL window, fills only a small portion of the plotting window. Similarly, when output to an EPS file, this image will only fill a small portion of the bounding box. When the resulting EPS file is brought into a desktop publishing program, it becomes very hard to properly scale the image since the aspect ratio of the bounding box bears no relation to the aspect ratio of the image itself.

To solve this problem, use the XSIZE and YSIZE keywords to the DEVICE procedure to make the bounding box just large enough to contain the image. Since IDL uses a resolution of 1000 dots per centimeter with the PostScript device, the correct XSIZE and YSIZE (in centimeters) can be computed as:

- $XSIZE = \text{Width of image in pixels} / 1000.0 \text{ pixels per cm}$
- $YSIZE = \text{Height of image in pixels} / 1000.0 \text{ pixels per cm}$

Note

The values of XSIZE and YSIZE for this device are effectively limited to a maximum of 11 inches due to the size of the memory map employed to render the graphics information.

The following IDL procedure demonstrates this technique. This procedure reads an X Windows Dump file and writes it back out as a properly-sized, 8-bit-color Encapsulated PostScript file:

```

PRO XWDTOEPS, filename
; Read the XWD file. Pixel intensity information is stored
; in the variable 'array'. Values to reconstruct the color
; table are stored in 'r', 'g', and 'b':
array = READ_XWD(filename, r, g, b)
; Reconstruct the color table:
TVLCT, r,g,b
; Display the image in an IDL window:
TV, array
; Find the size of the picture. The width of the picture
; (in pixels) is stored in s[1]. The height of the picture
; is stored in s[2]:
s = SIZE(array)
; Take the 'xwd' (for X Windows Dump) extension off of
; the old filename and replace it with 'eps':
fl = STRLEN(filename)
filename = STRMID(filename, 0, fl-4)
filename = filename + '.eps'
PRINT, 'Making file: ', filename
PRINT, s
; Set the plotting device to PostScript:
SET_PLOT, 'ps'
; Use the DEVICE procedure to make the output encapsulated,
; 8 bits, color, and only as wide and high as it needs to
; be to contain the XWD image:
DEVICE, /ENCAPSUL, BITS_PER_PIXEL=8, /COLOR, $
    FILENAME=filename, XSIZE=S[1]/1000., $
    YSIZE=S[2]/1000.
; Write the image to the file:
TV, array
; Close the file:
DEVICE, /CLOSE
; Return plotting to X Windows:
SET_PLOT, 'x'
END

```

Multiple Plots on the Same Page

To put multiple plots on the same PostScript page, use the `!P.MULTI` system variable (described in more detail in “!P” on page 5669). `!P.MULTI` is a 5-element integer array that controls the number of rows and columns of plots to make on a page or in a graphics window.

The first element of !P.MULTI is a counter that reports how many plots remain on the page. The second element of !P.MULTI is the number of columns per page. The third element is the number of rows per page.

For example, the following lines of code create a PostScript file, `multi.ps`, with 6 different plots arranged as 2 columns and 3 rows:

```
; Set plotting to PostScript:
SET_PLOT, 'PS'
; Set the filename:
DEVICE, FILENAME='multi.ps'
; Make IDL's plotting area hold 2 columns and 3 rows of plots:
!P.MULTI = [0, 2, 3]
; Create a simple dataset:
A = FINDGEN(10)
; Make 6 different plots:
PLOT, A
PLOT, SIN(A)
PLOT, COS(A)
PLOT, TAN(A)
PLOT, TANH(A)
PLOT, SINH(A)
; Close the file:
DEVICE, /CLOSE
; Return plotting to Windows:
SET_PLOT, 'win'
; Reset plotting to 1 plot per page:
!P.MULTI = 0
```

The resulting file produces a set of plots as shown in the following figure:

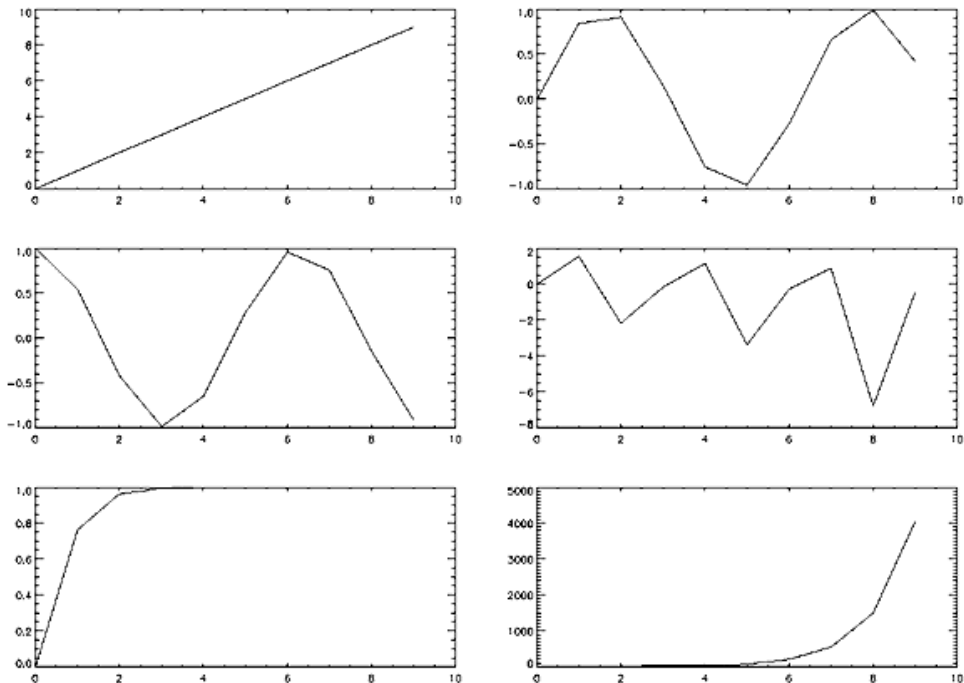

Figure A-2: Multiple plots on a single page produced by setting the !P.MULTI system variable.

Importing IDL Plots into Other Documents

This section shows how to generate IDL PostScript graphics so that they can be inserted into other documents. It also provides several examples of how the PostScript graphics device is used. Simply omit the `ENCAPSULATED` keyword from the calls to `DEVICE` if you wish to produce plots that can be printed directly. The following figure is an encapsulated PostScript file suitable for inclusion in other documents. The figure was produced with the following IDL statements. Note the use of the `ENCAPSULATED` keyword in the call to `DEVICE`:

```

; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic1.ps'
x = FINDGEN(200)

```

```

; Plot the sine wave:
PLOT, 10000 * SIN(x/5) / EXP(x/100), $
      LINESTYLE = 2, TITLE = 'IDL PostScript Plot', $
      XTITLE = 'Point Number', YTITLE='Y Axis Title', $
      FONT = 0
; Add the cosine:
OPLOT, 10000 * COS(x/5) / EXP(x/100), LINESTYLE = 4
; Annotate the plot:
XYOUTS, 100, -6000, 'Sine', FONT = 0
OPLOT, [120, 180], [-6000, -6000], LINESTYLE = 2
XYOUTS, 100, -8000, 'Cosine', FONT = 0
OPLOT, [120, 180], [-8000, -8000], LINESTYLE = 4

```

Figure A-3: Sample PostScript plot using Helvetica font.

The following figure is a more complicated plot. It demonstrates some of the three-dimensional plotting capabilities of IDL. It was produced with the following IDL statements:

```

; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic2.ps'
; Access the data:
OPENR, 1, FILEPATH('abnorm.dat', SUBDIR=['examples', 'data'])
aa = ASSOC(1, BYTARR(64, 64, /NOZERO))
; Get a smoothed version:
a = SMOOTH(aa[0], 3)

```

```

; Generate the surface:
SURFACE, a, /SAVE, ZAXIS = 1, XSTYLE = 1, YSTYLE = 1
; Add the contour:
CONTOUR, a, /T3D, /NOERASE, ZVALUE = 1, $
    XSTYLE = 1, YSTYLE = 1, C_LINestyle = [0,1,2], $
    TITLE = 'IDL PostScript Plot'
CLOSE, 1

```

Figure A-4: Three-Dimensional Plot with Vector-Drawn Characters

The following figure illustrates polygon filling. It was produced with the following IDL statements:

```

SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic3.ps'
x = FINDGEN(200)
; Upper sine wave:
a = 10000 * sin(x / 5) / exp(x / 100)
PLOT, a, /NODATA, TITLE = 'IDL PostScript Plot', $
    XTITLE='Point Number', YTITLE='Y Axis Title', $
    FONT = 0
; Vector of X vertices for polygon filling. Note that the
; ROTATE(V,2) function call returns the vector V in reverse order:
C = [X, ROTATE(X, 2)]

```

```

; Vector of Y vertices for polygon filling:
D = [A, ROTATE(A-2000, 2)]
; Fill the region using an intensity of about 75% white:
POLYFILL, C, D, COLOR=192

```

Figure A-5: Polygon Filling Example

The following figure illustrates IDL PostScript images. In this case, the same image is reproduced four times. In each case, a different number of bits are used per image pixel. It was produced with the following IDL statements:

```

SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic4.ps'
; Open image file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
; Variable to hold image:
a = BYTARR(192, 192, /NOZERO)
; Input the image:
READU, 1, a
; Done with the file:
CLOSE, 1
; Add a color table ramp to the bottom of the image:
A[0,0] = BYTSCL(INDGEN(192))#REPLICATE(1,16)
; Output the image four times:
FOR i = 0,3 DO BEGIN
    ; Use 1, 2, 4, and 8 bits per pixel:
    DEVICE, BITS_PER_PIXEL=2^i

```

```
; Output using TV with position numbers 0, 1, 2, and 3:  
TV, a, i, XSIZE=2.5, YSIZE=2.5, /INCHES  
ENDFOR
```

Figure A-6: 1, 2, 4, and 8-bit PostScript Images

The Regis Terminal Device

Device Keywords Accepted by the REGIS Device:

[AVERAGE_LINES](#), [CLOSE_FILE](#), [FILENAME](#), [PLOTTER_ON_OFF](#),
[SET_CHARACTER_SIZE](#), [TTY](#), [VT240](#), [VT340](#)

IDL provides Regis graphics output for the DEC VT240, VT330, and VT340 series of terminals. To output graphics to such terminals, issue the IDL command:

```
SET_PLOT, 'REGIS'
```

This causes IDL to use the Regis driver for producing graphical output.

Defaults for Regis Devices

The default setting for Regis output is: VT340, 16 colors, 4 bits per pixel.

Regis Limitations

- Four colors are available with VT240 and VT241 terminals, sixteen colors are available with the VT330 and VT340.
- Thick lines are emulated by filling polygons. There may be a difference in linestyle appearance between thick and normal lines.
- Image output is slow and is of poor quality, especially on the VT240 series. The VT240 is only able to write pixels on even numbered screen lines. IDL offers two methods of writing images to the 240:
 - Even and odd pairs of rows are averaged and written to the screen. An n, m image will occupy n columns and m screen rows. If this method is selected, graphics and image coordinates coincide. This method is the default (`AVERAGE_LINES = 1`). Routines that rely on a uniform graphics and image coordinate system, such as `SHADE_SURF`, work only in this mode.
 - Each line of the image is written to the screen, displaying every image pixel. An n, m image occupies $2m$ lines on the screen. (`AVERAGE_LINES = 0`). Graphics and image coordinates coincide only at the lower left corner of the image.
- Pixel values cannot be read back from the terminal, rendering the `TVRD` function inoperable.

The Tektronix Device

Device Keywords Accepted by the REGIS Device:

`CLOSE_FILE`, `COLORS`, `FILENAME`, `GIN_CHARS`, `PLOT_TO`,
`RESET_STRING`, `SET_CHARACTER_SIZE`, `SET_STRING`, `TEK4014`, `TEK4100`,
`TTY`

The Tektronix 4000 (4010, 4014, etc.), 4100 and 4200 series of graphics terminals (and the multitude of terminals and microcomputers that emulate them) are among the most common graphics devices available. To use IDL graphics with such terminals, issue the command:

```
SET_PLOT, 'TEK'
```

This causes IDL to use the Tektronix driver for producing graphical output. Once the Tektronix driver is enabled via `SET_PLOT`, the `DEVICE` procedure is used to control its actions, and to configure IDL for the specific features of your terminal. If you never call the `DEVICE` procedure, IDL assumes a plain vanilla Tektronix 4000 series compatible terminal. The 4200 series is upwardly compatible with the 4100 series; all references to the 4100 series also include the 4200 series. To set up IDL for use with a 4100 series compatible terminal with n colors, enter the following commands:

```
SET_PLOT, 'TEK'  

DEVICE, /TEK4100, COLORS = n
```

The number of colors should be set to 2^B where B is the number of bit planes in your terminal. If you use a Tektronix compatible terminal that requires calling the `DEVICE` procedure for configuration, you should probably create and use a start-up procedure that calls the `DEVICE` procedure, as described in “[Startup File](#)” (Chapter 1, *Using IDL*). Because of the tremendous variation among the requirements and abilities of these terminals, it is crucial that you configure IDL properly for your terminal. In particular, the mode switching character sequences, set by the keyword parameters `SET_STRING` and `RESET_STRING` must be set correctly.

The DEVICE Procedure For Tektronix Terminals

The default setting for Tektronix output is: 10-bit coordinates, 4000 series terminals, and no use of color. The `DEVICE` keywords can be used to modify these defaults.

Tektronix Limitations

- The line drawing procedures work with all models. Line style and color capabilities vary greatly among terminal models and/or emulation programs.

- Color and the display of images (albeit very slowly and frequently of a poor quality because of the small number of colors) is usable only with 4100 series terminals. Hardware polygon fill and thick lines do not work with the 4000 series.
- The image coordinate system does not match the graphics coordinate system. The graphics coordinates range from 0 to 3071 in Y, and from 0 to 4095 in X. Image coordinates vary according to terminal model. A typical range is from 0 to 479 in Y, and 0 to 639 in X. Because of this, the SHADE_SURF procedure does not work with Tektronix terminals.

Warning

Not all 4100 series terminals are capable of displaying images—the Tektronix pixel operations option is required. Many terminal emulators do not emulate this option. The Tektronix commands used to output images are: RU, begin pixel operations, RS, set pixel viewport, and RP, raster write. If your terminal or emulator does not accept these commands, you will not be able to display images.

- The Tektronix graphics protocol does not allow the specification of line thickness. Lines with a thickness more than 1.0 are drawn using polygon filling in the case of 4100 series terminals. With 4000 series terminals, thick lines are emulated by drawing multiple thin lines. This scheme will produce artifacts on some Tektronix emulating devices because of differing resolutions, normal line thicknesses and inexact coordinate conversions.

Tektronix Device Limitations

Usage of Tektronix and Tektronix-compatible terminals with IDL has the following limitations:

- Image coordinates do not match the coordinates used by the rest of the graphic procedures. This is because no two models of Tektronix terminals are compatible. The graphics procedures utilize the default coordinate system of 1024 by 780, or 4096 by 3120 in the 12-bit mode. The size of the pixel memory and coordinate system vary widely between models. The *Position* parameter of the TV and TVSCL procedures does not work.
- The cursor can not be positioned from the computer meaning that the TVCRS procedure cannot be used with the Tektronix driver.
- Pixel values may not be read back from the terminal, rendering the TVRD function inoperable.

The Microsoft Windows Device

Device Keywords Accepted by the WIN Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR,
CURSOR_ORIGINAL, CURSOR_STANDARD, DECOMPOSED,
GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM,
GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE,
GET_WINDOW_POSITION, PRINT_FILE, RETAIN, SET_CHARACTER_SIZE,
SET_FONT, SET_GRAPHICS_FUNCTION, TRANSLATION, WINDOW_STATE

The Microsoft Windows version of IDL uses the “WIN” device by default. This device is similar to the X Windows device described below. The “WIN” device is only available in IDL for Windows.

To set plotting to the Microsoft Windows device, use the command:

```
SET_PLOT, 'WIN'
```

The X Windows Device

Device Keywords Accepted by the X Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR, CURSOR_IMAGE, CURSOR_MASK, CURSOR_ORIGINAL, CURSOR_STANDARD, CURSOR_XY, DECOMPOSED, DIRECT_COLOR, FLOYD, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE, GET_VISUAL_NAME, GET_WINDOW_POSITION, GET_WRITE_MASK, ORDERED, PSEUDO_COLOR, RETAIN, SET_CHARACTER_SIZE, SET_FONT, SET_GRAPHICS_FUNCTION, SET_TRANSLATION, SET_WRITE_MASK, STATIC_COLOR, STATIC_GRAY, THRESHOLD, TRUE_COLOR, TTY, WINDOW_STATE

X Windows is a network-based windowing system developed by MIT's project Athena. IDL uses the X System (often referred to simply as "X"), to provide an environment in which the user can create one or more independent windows, each of which can be used for the display of graphics and/or images.

In the X system, there are two basic cooperating processes: *clients* and *servers*. A server consists of a display, keyboard, and pointer (such as a mouse) as well as the software that controls them. Client processes (such as IDL) display graphics and text on the screen of a server by sending X protocol requests across the network to the server. Although in the most common case, the server and client reside on the same machine, this network based design allows much more elaborate configurations.

To use X Windows as the current graphics device, issue the IDL command:

```
SET_PLOT, 'X'
```

This causes IDL to use the X Window System for producing graphical output. Once the X driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the X Windows driver.

Multi-Monitor Configurations and X Windows

IDL supports multiple monitor configurations on X Windows in two ways:

- **X Multi-Screen** — The core method for an X server to handle more than one monitor. Each monitor is assigned a *screen* or separate and independent drawing surface. You can move the pointing device from one monitor to another, but cannot drag windows between monitors. Each screen is addressed by the final digit in the X Display name (e.g. the 1 in `ajax:0.1`). IDL applications use the `DISPLAY_NAME` keyword on `WIDGET_BASE` to specify on which monitor to open the widget.
- **X with XINERAMA Extension** — XINERAMA is a popular extension used to make multiple monitors appear as one logical screen to the application. IDL applications simply use offsets or locations to specify the desired monitor.

Direct Graphics Limitations

In an X Multi-Screen configuration you can open a Direct Graphics window only on the default Display connection. This applies both to stand-alone Direct Graphics windows (e.g., `PLOT`) and `WIDGET_DRAW` widgets created with the `GRAPHICS_LEVEL` keyword set equal to any value other than 2.

In an XINERAMA configuration you can draw Direct Graphics on any monitor. This is because the extended desktop is one logical connection and is addressed with one X Display Name.

See the [IDLsysMonitorInfo](#) object for more information.

X Windows Visuals

Visuals specify how the hardware deals with color. The X Window server (your display) may provide colors or only gray scale (black and white), or both. The color tables may be changeable from within IDL (read-write), or may be fixed (read-only). The value of each pixel value may be mapped to any color (Un-decomposed Colormap), or certain bits of each pixel are dedicated to the red, green, and blue primary colors (Decomposed Colormap).

There are six X Windows visual classes—read-write and read-only visuals for three types of displays: Gray Scale, Pseudo Color, and Decomposed Color. The names of the visuals are shown in the following table:

Visual Name	Writable	Description
StaticGray	no	Gray scale
GrayScale	yes	Gray scale

Table A-19: X Windows Visual Classes

Visual Name	Writable	Description
StaticColor	no	Undecomposed color
PseudoColor	yes	Undecomposed color
TrueColor	no	Decomposed color
DirectColor	yes	Decomposed color

Table A-19: X Windows Visual Classes

IDL supports all six types of visuals, although not at all possible depths. UNIX X Window System users can use the command `xdpypinfo` to determine which visuals are supported by their systems.

Each X Window server has a default visual class. Many servers may provide multiple visual classes. For example, a server with display hardware that supports an 8-bit-deep, un-decomposed, writable color map (PseudoColor), may also easily provide StaticColor, StaticGray, and GrayScale visuals.

You can select the visual used by IDL using the DEVICE procedure before a window is created, or by including the resource `idl.gr_visual` in your X defaults file, as explained in [“Setting the X Window Defaults”](#) on page 5602.

How IDL Selects a Visual Class

When opening the display, IDL asks the display for the following visuals, in order, until a supported visual class is found:

1. TrueColor, 24-bit, then 16-bit, then 15-bit
2. PseudoColor, 8-bit, then 4-bit
3. DirectColor, 24-bit
4. StaticColor, 8-bit, then 4-bit
5. GrayScale, any depth
6. StaticGray, any depth

You can override this behavior by using the DEVICE routine to specify the desired visual class and depth before you create a window. For example, if you are using a display that supports both the TrueColor, 24-bit-deep visual, and an 8-bit-deep PseudoColor visual, IDL will select the 24-bit-deep TrueColor visual. To instead use PseudoColor, issue the following command before creating a window:

```
DEVICE, PSEUDO_COLOR = 8
```

The colormap/visual class combination is chosen when IDL first connects with the X Window server. Note that if you connect with the X server by creating a window or using the `DEVICE` keyword to the `HELP` procedure, the visual class will be set; it then cannot be changed until IDL is restarted. If you wish to use a visual class other than the default, be sure to set it with a call to the `DEVICE` procedure *before* creating windows or otherwise connecting with the X Window server.

Windows are created in two ways:

1. Using the `WINDOW` procedure. `WINDOW` allows you to explicitly control many aspects of how the window is created.
2. If no windows exist and a graphics operation requiring a window is executed, IDL implicitly creates window 0 with the default characteristics.

Once the visual class is selected, all subsequently-created windows share the same class and colormap. The number of simultaneous colors available is stored in the system variable `!D.N_COLORS`. The visual class and number of colors, once initialized, cannot be changed without first exiting IDL.

How IDL Obtains a Colormap

IDL chooses the type of colormap in the following manner:

- By default, the shared colormap is used whenever possible (i.e., whenever IDL is using the default visual for the system). All available colors from the shared colormap are allocated for use by IDL. This is what happens when no window currently exists and a graphics operation causes IDL to implicitly create one.
- If the number of colors to use is explicitly specified using the `COLORS` keyword with the `WINDOW` procedure, IDL attempts to allocate the number of colors specified from the shared colormap using the default visual of the screen. If there aren't enough colors available, a private colormap with that number of colors is used instead.
- Specifying a negative value for the `COLORS` keyword to the `WINDOW` procedure causes IDL to attempt to use the shared colormap, allocating all but the specified number of colors. For example:

```
WINDOW, COLORS = -8
```

allocates all but 8 of the currently available colors. This allows other applications that might need their own colors to run in tandem with IDL.

- If a visual type and depth is specified, via the `DEVICE` procedure, which does not match the default visual of the screen, a new, private, colormap is created.

Using Color Under X

Colormaps define the mapping from color index to screen color. Two attributes of colormaps are important to the IDL user: they may be *private* or *shared*; and they may be *static* or *writable*. These different types of colormaps are described below.

Shared Colormaps

The window manager creates a colormap when it is started. This is known as the default colormap, and can be shared by most applications using the display. When each application requires a colormap entry (i.e., a mapping from a color index to a color), it allocates one from this shared table. Advantages and disadvantages of shared colormaps include:

- Using the shared colormap ensures that all applications share the available colors without conflict. A given application will not change a color that is allocated to a different application. In the case of IDL it means that IDL can change the colors it has allocated without changing the colors in use by the window manager or other applications.
- The window system interface routines must translate between the actual and allocated pixel values, significantly slowing the transfer of images.
- The shared colormap might not have enough colors available to perform the desired operations with IDL.
- The number of available colors in the shared colormap depends on the window manager in use and the demands of other applications. Thus, the number of available colors can vary.
- The allocated colors in a shared colormap do not generally start at zero and they are not necessarily contiguous. This makes it difficult to use the write mask for certain operations.

Private Colormaps

An application can create its own private color map. Most hardware can only display a single colormap at a time, so these private colormaps are called virtual color maps, and only one at a time is actually in use and visible. When the window manager gives the color focus to a window with a private colormap, the X window system loads its virtual colormap into the hardware colormap.

- Every color index supported by the hardware is available to IDL, improving the quality of images.

- Allocated colors always start at zero and are contiguous. This simplifies using the write mask.
- No translation between internal pixel values and the values required by the server is required, making the transfer of images more efficient.
- When the IDL colormap is loaded, other applications are displayed using the wrong colors. Furthermore, colors from the shared colormap are usually allocated from the lower end of the map first. These are the colors allocated by the window manager for such things as window borders, the color of text, and so forth. Since most IDL colormaps have very dark colors in the lower entries, the end effect with the IDL colormap loaded is that the non-IDL portions of the screen go blank.

Static Colormaps

As mentioned above, the contents of static colormaps are determined outside of IDL and cannot be changed. When using a static colormap, the TVLCT procedure simulates writable colormaps by finding the closest RGB color entry in the colormap to the requested color. The colormap translation table is then set to map IDL color indices to those of the closest colors in the colormap.

The colors present in the colormap may, and probably will, *not* match the requested colors exactly. For example, with a typical static color map, loading the IDL standard color table number 0, which consists of 256 intensities of gray, results in only 8 or 16 distinct intensities.

With static colormaps, loading a new color table does not affect the appearance of previously written objects. The internal translation tables are modified, which only affects objects that are subsequently written.

Color Translation

As mentioned above, colors from the shared colormap do not necessarily start from index zero, and are not necessarily contiguous. IDL preserves the illusion of a zero based contiguous colormap by maintaining a translation table between user color indices, which range from 0 to !D.TABLE_SIZE, and the actual pixel values allocated from the X server. Normally, the user need not be concerned with this translation table, but it is available using the statement:

```
DEVICE, TRANSLATION=T
```

This statement stores the current translation table, a 256 element byte vector, in the variable T. Element zero of the vector contains the value pixel allocated for the zeroth color in the IDL colormap, and so forth. In the case of a private colormap, each

element of the translation vector contains its own index value, because private colormaps start at zero and are contiguous.

The translation table may be bypassed, allowing direct access to the display's color indices, by setting the `BYPASS_TRANSLATION` keyword in the `DEVICE` procedure.

```
DEVICE, /BYPASS_TRANSLATION
```

Translation can be reestablished by setting the keyword to zero:

```
DEVICE, BYPASS_TRANSLATION=0
```

By default, the color translation tables are bypassed if the visual type is `TrueColor` or the visual type is `DirectColor` with a private colormap.

Using Pixmaps

X Windows can direct graphics to *windows* or *pixmap*s. Windows are the usual windows that appear on the screen and contain graphics. Pixmap are invisible graphics memory contained in the server. Drawing to a window produces a viewable result, while drawing to a pixmap simply updates the pixmap memory.

Pixmap are useful because it is possible to write graphics to a pixmap and then copy the contents of the pixmap to a window where it can be viewed. Furthermore, this copy operation is very fast because it happens entirely within the server. Provided enough pixmap memory is available, this technique works very well for animating a series of images by placing the images into pixmap memory and then sequentially copying them to a visible window.

To create a pixmap, use the `PIXMAP` keyword with the `WINDOW` procedure. For example, to create a square pixmap with 128 pixels per side as IDL window 1, use the command:

```
WINDOW, 1, /PIXMAP, XSIZE=128, YSIZE=128
```

Once they are created, pixmaps are treated just like normal windows, although some operations (`WSHOW` for instance) don't do anything useful when applied to a pixmap.

The following procedure shows how animation can be done using pixmap memory. It uses a series of 15 heart images taken from the file `abnorm.dat`. This file is supplied with all IDL distributions in the `examples/data` subdirectory of the main IDL directory. It creates a pixmap and writes the heart images to it. It then uses the `COPY` keyword of the `DEVICE` procedure to copy the images to a visible window.

Note

Pressing any key causes the display process to halt. If you are using the IDL Workbench interface, make sure the IDL Command Line view has the focus before pressing a key.

```

; Animate heart series:
PRO animate_heart
; Open the file containing the images:
OPENR, u, FILEPATH('abnorm.dat', SUBDIR = ['examples','data']), $
    /GET_LUN
; Associate a file variable with the file. Each heart image
; is 64x64 pixels:
frame = ASSOC(u, BYTARR(64,64, /NOZERO))
; Window 0 is a pixmap which is 4 images tall and 4
; images wide. The images will be placed in this pixmap:
WINDOW, 0, /PIXMAP, XSIZE = 512, YSIZE = 512
; Write each image to the pixmap. SMOOTH is used to improve
; the appearance of each image and REBIN is used to
; enlarge/shrink each image to the final display size:
FOR i=0, 15-1 DO TV, REBIN(SMOOTH(frame[i],3), 128, 128),i
; Close the image file and free the file unit:
FREE_LUN, u
; The visible window will be used to display the animated heart
; cycle:
WINDOW, XSIZE = 128, YSIZE=128, TITLE='Heart', /FREE
; Current frame number:
i = 0L
; Display frames until any key is pressed:
WHILE GET_KBRD(0) EQ '' DO BEGIN
; Compute x and y locations of pixmap image's lower left corner:
    x = (i mod 4) * 128 & y = 384 - (i/4) * 128
; Copy the next image from the pixmap to the visible window:
DEVICE, COPY = [x, y, 128, 128, 0, 0, 0]
; Keep track of total frame count:
i = (i + 1) MOD 15
ENDWHILE
END

```

Animation sequences with more and/or larger images can be made. See the documentation for the XANIMATE procedure, which is a more generalized embodiment of the above procedure.

Note

Some X Windows servers will refuse to create a pixmap that is larger than the physical screen in either dimension.

Note

Excessive pixmap allocation can exhaust virtual storage, causing some X Windows servers to become unresponsive.

How Color is Interpreted for a TrueColor Visual

How a color (such as !P.COLOR) is interpreted by IDL (when a TrueColor visual is being utilized) depends in part upon the decomposed setting for the device.

To retrieve the decomposed setting:

```
DEVICE, GET_DECOMPOSED = currentDecomposed
```

To set the decomposed setting:

```
DEVICE, DECOMPOSED = newDecomposed
```

If the decomposed value is zero, colors (like !P.COLOR) are interpreted as indices into IDL's color table. A color should be in the range from 0 to !D.TABLE_SIZE - 1. The IDL color table contains a red, green, and blue component at a given index; each of these components is in the range of 0 up to 255.

Note

IDL's color table does not map directly to a hardware color table for a TrueColor visual. If IDL's color table is modified, for example using the LOADCT or TVLCT routines, then the new color table will only take effect for graphics that are drawn after it has been modified.

If the decomposed value is non-zero, colors (like !P.COLOR) are interpreted as a combination of red, green, and blue settings. The least significant 8 bits contain the red component, the next 8 bits contain the green component, and the most significant 8 bits contain the blue component.

In either case, the most significant bits of each of the resulting red, green, and blue components are utilized. The number of bits utilized per component depends upon the red, green, and blue masks for the visual. On UNIX systems, a new field (Bits Per RGB) has been added to the output from HELP, /DEVICE. This Bits Per RGB field indicates the amount of bits utilized for each component.

Tip

The UNIX command `xdpinfo` also provides information about each of the visuals.

Setting the X Window Defaults

You can set the initial default value of the following parameters by setting resources in the file `.Xdefaults` file in your home directory as follows:

Resource Name	Description
<code>idl.colors</code>	The number of colors used by IDL.
<code>idl.gr_depth</code>	The depth, in bits, of the visual used by IDL.
<code>idl.retain</code>	The default setting for the <i>retain</i> parameter: 0=none, 1= by server, 2=by IDL.
<code>idl.gr_visual</code>	The type of visual: StaticGray, GrayScale, StaticColor, PseudoColor, TrueColor, or DirectColor.

Table A-20: IDL/ X Window Defaults

For example, to set the default visual to PseudoColor, and to allocate 100 colors, insert the following lines in your defaults file:

```
idl.gr_visual: PseudoColor
idl.colors: 100
```

The Z-Buffer Device

Device Keywords Accepted by the Z Device:

[CLOSE](#), [DECOMPOSED](#), [GET_DECOMPOSED](#), [GET_GRAPHICS_FUNCTION](#), [GET_PIXEL_DEPTH](#), [GET_WRITE_MASK](#), [SET_CHARACTER_SIZE](#), [SET_COLORS](#), [SET_FONT](#), [SET_GRAPHICS_FUNCTION](#), [SET_PIXEL_DEPTH](#), [SET_RESOLUTION](#), [SET_WRITE_MASK](#), [Z_BUFFERING](#)

The IDL Z-buffer device is a pseudo device that draws 2-D or 3-D graphics in a buffer contained in memory. This driver implements the classic Z buffer algorithm for hidden surface removal. Although primarily used for 3-D graphics, the Z-buffer driver can be used to create 2-D objects in a frame buffer in memory. The resolution (dimensions) of this device can be set by the user.

All of the IDL plotting and graphics routines work with the Z-buffer device driver. In addition, the POLYFILL procedure has a few keyword parameters, allowing Gouraud shading and warping images over 3-D polygons, that are only effective when used with the Z-buffer.

When used for 3-D graphics, two buffers are present: an 8-bit-deep or 24-bit deep frame buffer that contains the picture; and a 16-bit-deep Z-buffer of the same resolution, containing the z-value of the visible surface of each pixel. The Z-buffer is initialized to the depth at the back of the viewing volume. When objects are drawn, the z-value of each pixel is compared with the value at the same location in the Z-buffer, and if the z-value is greater (closer to the viewer), the new pixel is written in the frame buffer and the Z-buffer is updated with the new z-value.

The frame buffer is 8 bits deep by default, but can be configured to be 24 bits deep using the [SET_PIXEL_DEPTH](#) keyword to the DEVICE routine. In 8-bit mode, the low-order 8 bits of any color specification are written to the 8-bit frame buffer. In 24-bit mode, the behavior depends on the value of the [DECOMPOSED](#) keyword to the DEVICE routine. When DECOMPOSED=1 (the default), the 24-bit color specification is stored in the 24-bit frame buffer, providing TrueColor functionality. When DECOMPOSED=0, the lower 8 bits of the color specification are used to index the current color lookup table to obtain 3-channel color information to store in the 24-bit frame buffer. Use the [SET_COLORS](#) keyword to the DEVICE routine to limit the maximum color index value used in this process.

The Z-buffer device is a “pseudo device” in that drawing commands update buffers in memory rather than sending commands to a physical device or file. The TVRD

function reads the contents of either buffer to an IDL array. This array may then be further processed, written to a file, or output to a raster-based graphics output device.

The Z-buffer driver can be used for 2-D graphics by disabling the depth computations.

To use the Z-buffer as the current graphics device, issue the IDL command:

```
SET_PLOT, 'Z'
```

Once the Z-buffer driver is enabled, the `DEVICE` procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the Z-buffer driver and the amount of memory used for the buffers.

Reading and Writing Buffers

The contents of both frame and depth buffers are directly accessed by the `TV` (or `TVSCL`) and `TVRD` routines via the `CHANNEL` keyword. Access the buffers as follows, depending on the device pixel depth:

8-bit Pixel Depth

When the Z buffer device pixel depth is 8 bits (the default), the assignments for the `CHANNEL` keyword are:

CHANNEL	Buffer	Data Type
0	8-bit Frame Buffer (color indices)	byte
1	16-bit Depth Buffer	signed integer

Use `CHANNEL=1` and set the `WORDS` keyword when reading or writing the depth buffer in 8-bit mode.

The Z buffer device ignores the `TRUE` keyword in 8-bit mode.

24-bit Pixel Depth

When the device pixel depth is 24 bits, the assignments for the CHANNEL keyword are:

CHANNEL	Buffer	Data Type
0	3 8-bit Frame Buffer channels (Red, Green, Blue)	byte
1	8-bit Frame Buffer (Red channel)	byte
2	8-bit Frame Buffer (Green channel)	byte
3	8-bit Frame Buffer (Blue channel)	byte
4	16-bit Depth Buffer	signed integer

Use CHANNEL=4 and set the WORDS keyword when reading or writing the depth buffer in 24-bit mode.

In 24-bit mode, the interleave is controlled by the value of the TRUE keyword:

TRUE	Interleave
0	None (see below)
1	Pixel
2	Row
3	Band

If TRUE=0:

- The TV and TVSCL routines replicate the single channel of input data into each of the three frame buffer channels.
- The TVRD routine returns a one-channel image where each pixel is the maximum of the three pixel components in the frame buffer.

Using the Z Buffer

The normal procedure is to set the graphics device to “Z”, draw the objects, read the frame buffer, and then select another graphics device and write the image. For example, to create an image with the Z-buffer driver and then display it on an X-Window display:

```
; Select Z-buffer device:
```

```

SET_PLOT, 'Z'
; Write objects to the frame buffer using normal graphics
; routines, e.g. PLOT, SURFACE, POLYFILL
... ..
; Read back the entire frame buffer:
a=TVRD()
; Select X Windows:
SET_PLOT, 'X'
; Display the contents of the frame buffer:
TV, a

```

To read the depth values in the Z-buffer, use the command:

```
a = TVRD(CHANNEL=1, /WORDS)
```

To write the depth values, use the command:

```
TV, a, /WORDS, CHANNEL=1
```

The TV, TVSCL, and TVRD routines write or read pixels directly to a rectangular area of the designated buffer without affecting the other buffer.

Z-Axis Scaling

The values in the depth buffer are short integers, scaled from -32765 to +32765, corresponding to normalized Z-coordinate values of 0.0 to 1.0, where 1.0 represents the plane closest to the viewer.

Polyfill Procedure

The Z device draws patterns specified via the PATTERN keyword to the POLYFILL procedure using one of two methods:

- The default method treats the pattern image as a background pattern, drawing it only inside the boundaries of the polygons. All graphics devices that render POLYFILL patterns can use this method.
- The alternate method emulates *texture mapping*, in which the pattern image is “warped” between the vertices of the polygons. This method is used when the IMAGE_COORDINATES keyword to POLYFILL is present, specifying which part of the image is warped to each vertex. This method is only available when using the Z device.

The following POLYFILL keywords are active only with the Z-buffer device: IMAGE_COORDINATES, IMAGE_INTERPOLATE, and TRANSPARENT. These parameters allow images, specified via the PATTERN keyword, to be warped over 2-D and 3-D polygons. The values of the IMAGE_INTERPOLATE and

TRANSPARENT keywords apply only when IMAGE_COORDINATES are specified.

The Z device converts all image data specified with the PATTERN keyword to BYTE.

Image data can be supplied in either an $[m \times n]$ array (a single-channel image), or as an $[3 \times m \times n]$ array (a three-channel image). Table A-21 describes how different types of image data interact with the device pixel depth and the DECOMPOSED setting of the device.

Z Device Pixel Depth	Number of PATTERN Channels	DECOMPOSED Setting	Resulting Pattern Image
8	1	n/a	Grayscale
8	3	n/a	Grayscale, created from first (red) channel
24	1	0	Color table applied
24	1	1	Single image channel replicated to grayscale
24	3	n/a	True color

Table A-21: Z Device Pixel Depth vs. Depth of POLYFILL Pattern

The IMAGE_COORDINATES keyword specifies a $[2 \times n]$ array containing the image space coordinates that correspond to each of the n vertices of the polygon.

The IMAGE_INTERPOLATE keyword indicates that bilinear interpolation is to be used, rather than the default nearest neighbor sampling.

Pixels less than the value of the TRANSPARENT keyword are not drawn, simulating transparency. The TRANSPARENT keyword is a byte value. A three-channel image pixel is not drawn only when all three components are less than the TRANSPARENT value. If performing color table lookup (Z device pixel depth is 24, PATTERN is one channel, and DECOMPOSED=0), the pixel is not drawn if the single-channel pixel is less than the transparent value.

For Gouraud shading of polygons, the COLOR keyword can contain an array specifying the color index for each polygon vertex.

Examples Using the Z-Buffer

This example forms a Bessel function, draws its shaded surface and overlays its contour, using the Z-buffer as shown in the following figure. The final output is directed to a PostScript file.

```
; Store the original display device
oldDevice = !D.NAME

; Select the Z-buffer:
SET_PLOT, 'Z'
n = 50 ; Size of array for Bessel

; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)

; Draw the surface, label axes in black, background in white:
SHADE_SURF, a, /SAVE, COLOR=1, BACKGROUND=255
nlev = 8 ; Number of contour levels

; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
    LEVELS=FINDBGEN(nlev)*1.5/nlev-.5, COLOR=1

; Read image:
b=TVRD()

; Select PostScript output:
SET_PLOT, 'PS'

; Select a file name for the output file
DEVICE, FILENAME = DIALOG_PICKFILE(FILE='zbuffer-1.ps')

; Output the image:
TV, b

; Close the new PostScript file:
DEVICE, /CLOSE

; Select the original device:
SET_PLOT, oldDevice
```

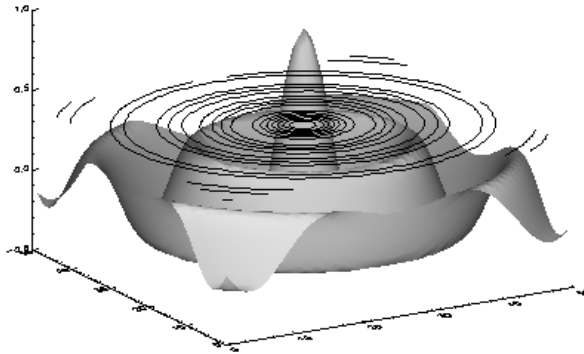

Figure A-7: Combined Shaded Surface and Contour Plot

If we use a 24-bit Z device, we can prepare a true color image that can then be displayed on a 24-bit display. (Here, we assume that the display monitor is a TrueColor device):

```

; Store the original display device
oldDevice = !D.NAME
DEVICE, GET_DECOMPOSED=oldDecomposed

; Select the Z-buffer:
SET_PLOT, 'Z'
DEVICE, SET_PIXEL_DEPTH=24, DECOMPOSED=0
LOADCT, 5
n = 50 ; Size of array for Bessel

; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)

; Draw the surface, label axes in black, background in white:
SHADE_SURF, a, /SAVE, COLOR=1, BACKGROUND=255
nlev = 8 ; Number of contour levels

; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
    LEVELS=FINDGEN(nlev)*1.5/nlev-.5, COLOR=1

; Read image:
b=TVRD(/TRUE)

; Select the original device and set window size:
SET_PLOT, oldDevice

```

```

DEVICE, DECOMPOSED=oldDecomposed
WINDOW, XSIZE=(SIZE(b))[2], YSIZE=(SIZE(b))[3]

; Output the image:
TV, b, /TRUE

```

Using the 24-bit Z device, we can also modify the example to use full 24-bit color specifications, rather than picking colors from a color table:

```

; Store the original display device
oldDevice = !D.NAME
DEVICE, GET_DECOMPOSED=oldDecomposed

SET_PLOT, 'Z'
DEVICE, SET_PIXEL_DEPTH=24, DECOMPOSED=1
n = 50 ; Size of array for Bessel

; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)

; Draw the surface and axes in red, background in purple:
SHADE_SURF, a, /SAVE, COLOR='00000d2'x, BACKGROUND='00ff80c0'x
nlev = 8 ; Number of contour levels

; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
  LEVELS=FINDGEN(nlev)*1.5/nlev-.5, $
  C_COLORS=['00ffff00'x, '0000ffff'x, '00ff00ff'x]

; Read image:
b=TVRD(/TRUE)

; Select original output and set window size:
SET_PLOT, oldDevice
DEVICE, DECOMPOSED=oldDecomposed
WINDOW, XSIZE=(SIZE(b))[2], YSIZE=(SIZE(b))[3]

; Output the image:
TV, b, /TRUE

```

The 24-bit Z buffer device is useful for creating a TrueColor image from an 8-bit display. The following example creates (and then displays) an image file from a display window that uses an 8-bit color lookup table.

```

; Read an image file containing elevation data
file = FILEPATH('worldelv.dat', $
  SUBDIRECTORY = ['examples', 'data'])
image = READ_BINARY(file, DATA_DIMS = [360, 360])

```

```

; Store the original display device
oldDevice = !D.NAME
DEVICE, GET_DECOMPOSED=oldDecomposed

; Write the image to the 24-bit Z buffer device, using a
; color lookup table. Note that we must set the DECOMPOSED
; keyword to zero to create the color image.
SET_PLOT, 'Z'
ERASE
DEVICE, SET_PIXEL_DEPTH=24
DEVICE, SET_RESOLUTION=[360,360]
DEVICE, DECOMPOSED=0
LOADCT, 33
TVLCT, 255,255,255, !D.TABLE_SIZE - 1
TVSCL, image

; Read the image array back from the Z buffer device
; and write it to a TIFF file.
new_image = TVRD(/TRUE)
new_file = GETENV('IDL_TMPDIR')+'world.tif'
WRITE_TIFF, new_file, new_image

; Change back to the original device
SET_PLOT, oldDevice
DEVICE, DECOMPOSED=oldDecomposed

; Read in the TIFF file and display it.
tif_image = READ_TIFF(new_file)
WINDOW, XSIZE=360, YSIZE=360, TITLE='Image read from TIFF file'
TV, tif_image, /TRUE

```

The following example warps an image to a cube as shown in the figure below. The lower two quadrants of the image are warped to the front two faces of the cube. The upper-right quadrant is warped to the top face of the cube.

```

; Read an image from a JPEG file and resize it to
; 100 by 100 pixels.
READ_JPEG, FILEPATH('rose.jpg', $
    SUBDIRECTORY=['examples', 'data']), rose
nx = 100
ny = 100
rose = CONGRID(rose, 3, nx, ny)

; Store the original display device
oldDevice = !D.NAME

; Change to the Z buffer device

```

```

SET_PLOT, 'Z'
DEVICE, SET_PIXEL_DEPTH=24, SET_RESOLUTION=[400,400]

; Make a greenish background:
ERASE, '80ff80'x

; Establish 3-D scaling as (0,1) cube:
SCALE3, XRANGE=[0,1], YRANGE=[0,1], ZRANGE=[0,1]

; Define vertices of cube. Vertices 0-3 are bottom, 4-7 are top:
verts = [[0,0,0], [1,0,0], [1,1,0], [0,1,0], $
         [0,0,1], [1,0,1], [1,1,1], [0,1,1]]

; Fill lower left face:
POLYFILL, verts[*], [3,0,4,7]], /T3D, PATTERN=rose, $
         IMAGE_COORD=[[0,0], [nx/2,0], [nx/2,ny/2], [0,ny/2]]

; Fill lower right face:
POLYFILL, verts[*], [0,1,5,4]], /T3D, PATTERN=rose, $
         IMAGE_COORD=[[nx/2,0], [nx-1,0], $
         [nx-1,ny/2], [nx/2,ny/2]]

; Fill top face:
POLYFILL, verts[*], [4,5,6,7]], /T3D, PATTERN=rose, $
         IMAGE_COORD = [[nx/2,ny/2], [nx-1,ny/2], $
         [nx-1,ny-1], [nx/2,ny-1]]

; Draw edges of cube in black:
PLOTS, verts[*], [0,4]], /T3D, COLOR=0

; Edges of top face:
PLOTS, verts[*], [4,5,6,7,4]], /T3D, COLOR=0
img = TVRD(/TRUE)

; Change back to the original device and display:
SET_PLOT, oldDevice
WINDOW, XSIZE=400, YSIZE=400
TV, img, /TRUE

```

Figure A-8: TrueColor Image Warped to a Cube Using the Z-Buffer

Appendix B

Graphics Keywords

The IDL Direct Graphics routines, `CURSOR`, `ERASE`, `PLOTS`, `POLYFILL`, `TV` (and `TVSCL`), `TVCRS`, `TVRD`, and `XYOUTS`, and the plotting procedures, `AXIS`, `CONTOUR`, `PLOT`, `OPLOT`, `SHADE_SURF`, and `SURFACE`, accept a number of common keywords. Therefore, instead of describing each keyword along with the description of each routine, this section contains a brief summary of each graphics keyword. Routine-specific keywords are documented in the description of the routine. The graphics keywords are described below. The name of each keyword is followed by a list of routines that accept that keyword. Keywords that have a direct correspondence to fields in a system variable (usually `!P`) are also indicated.

The keywords that control the plot axes are prefixed with the character ‘X’, ‘Y’, or ‘Z’ depending on the axis in question. These keywords correspond to fields in the axis system variables: `!X`, `!Y`, and `!Z`, and are described in more detail in [“Graphics System Variables”](#) on page 5664. The axis keywords are shown in the form `[XYZ]NAME`. For example, `[XYZ]CHARSIZE` refers to the three keywords `XCHARSIZE`, `YCHARSIZE`, and `ZCHARSIZE`, which control the size of the characters annotating the three axes.

The system variable fields that control this are !X.CHAR.SIZE, !Y.CHAR.SIZE, and !Z.CHAR.SIZE.

The following graphics keywords are discussed in this appendix:

BACKGROUND	ORIENTATION	[XYZ]STYLE
CHANNEL	POSITION	[XYZ]THICK
CHARSIZE	PSYM	[XYZ]TICK_GET
CHARTHICK	SUBTITLE	[XYZ]TICKFORMAT
CLIP	SYMSIZE	[XYZ]TICKINTERVAL
COLOR	T3D	[XYZ]TICKLAYOUT
DATA	THICK	[XYZ]TICKLEN
DEVICE	TICKLEN	[XYZ]TICKNAME
FONT	TITLE	[XYZ]TICKS
LINestyle	[XYZ]CHARSIZE	[XYZ]TICKUNITS
NOCLIP	[XYZ]GRIDSTYLE	[XYZ]TICKV
NODATA	[XYZ]MARGIN	[XYZ]TITLE
NOERASE	[XYZ]MINOR	Z
NORMAL	[XYZ]RANGE	ZVALUE

BACKGROUND

Accepted by: **CONTOUR**, **PLOT**, **SURFACE**.

System variable equivalent: !P.**BACKGROUND**.

The background color index or 24-bit color value to which all pixels are set when erasing the screen or page. The default is 0 (black). Not all devices support erasing the background to a specified color.

For example, to produce a black plot with a white background on an indexed-color display:

```
PLOT, Y, BACKGROUND = 255, COLOR = 0
```

Warning

If the **NOERASE** keyword (or **!P.NOERASE**) is set, the value of the **BACKGROUND** keyword (or **!P.BACKGROUND**) is ignored.

CHANNEL

Accepted by: **ERASE**, **TV**, **TVRD**, **TVSCL**. System variable equivalent: **!P.CHANNEL**.

This keyword specifies the memory channel for the operation. This parameter is ignored on display systems that have only one memory channel. When using a “decomposed” display system, the red channel is 1, the green channel is 2, and the blue channel is 3. Channel 0 indicates all channels. If omitted, **!P.CHANNEL** contains the default channel value.

Note

CONTOUR, **PLOT**, **SHADE_SURF**, and **SURFACE** also accept the **CHANNEL** keyword, but simply pass it to **ERASE**.

TrueColor Images

Images can be transferred to and from the display in either 8-bit or 24-bit mode. The **CHANNEL** parameter specifies the source or destination channel number for 8-bit images, and the **TRUE** keyword (see “**TrueColor Images**” on page 5578) indicates for 24-bit images the method of channel interleaving. If neither keyword parameter is present, the 8-bit image is written to all three-color channels, yielding the same effect as if the channel parameter is specified as 0.

For example, to transfer three 8-bit images contained in the arrays **R**, **G**, and **B** to their respective channels, use the following statements:

```

;Load red in channel 1:
TV, R, 0, 0, 1
;Load green in channel 2:
TV, G, 0, 0, 2
;Load blue in channel 3:
TV, B, 0, 0, 3

```

The position parameters (0, 0 above) can be altered to write to any location in the window.

The Z Buffer Device

When using the Z buffer device with a pixel depth of 8 bits per pixel:

- channel 0 is the 8-bit frame buffer
- channel 1 is the 16-bit depth buffer

When using the Z buffer device with a pixel depth of 24 bits per pixel:

- channel 0 specifies three 8-bit frame buffers containing the red, green, and blue channels
- channel 1 is the 8-bit frame buffer containing the red channel
- channel 2 is the 8-bit frame buffer containing the green channel
- channel 3 is the 8-bit frame buffer containing the blue channel
- channel 4 is the 16-bit depth buffer

CHARSIZE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#).
System variable equivalent: `!P.CHARSIZE`.

The overall character size for the annotation when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. A CHARSIZE of 1.0 is normal. The size of the annotation on the axes may be set, relative to CHARSIZE, with `xCHARSIZE`, where *x* is X, Y, or Z. The main title is written with a character size of 1.25 times this parameter.

CHARTHICK

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#).
System variable equivalent: `!P.CHARTHICK`.

An integer value specifying the line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

CLIP

Accepted by: [CONTOUR](#), [DRAW_ROI](#), [OPLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: `!P.CLIP`.

The coordinates of a rectangle used to clip the graphics output. The rectangle is specified as a vector of the form $[X_0, Y_0, X_1, Y_1]$, giving coordinates of the lower left and upper right corners, respectively. The default clipping rectangle is the plot window, the area enclosed within the axes of the most recent plot. Coordinates are specified in data units unless an overriding coordinate unit specification keyword is

present (i.e., NORMAL or DEVICE). If the clipping is provided in data or normalized units, the actual clipping rectangle is computed by converting those values to device units. The clipping itself always occurs in device space.

Note

The default is not to clip the output of PLOTS and XYOUTS. To enable clipping include the keyword parameter NOCLIP = 0. With PLOTS, POLYFILL, and XYOUTS, this keyword controls the clipping of vectors and vector-drawn text.

For example, to draw a vector using normalized coordinates with its contents clipped within a rectangle covering the upper left quadrant of the display:

```
PLOTS, X, Y, CLIP=[0.,.5,.5,1.0], /NORM, NOCLIP=0
```

COLOR

Accepted by: [AXIS](#), [CONTOUR](#), [DRAW_ROI](#), [ERASE](#), [OPLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: !P.COLOR.

Indexed Color Mode

Set this keyword to specify the color index of the data, text, line, or solid polygon fill to be drawn. If this keyword is omitted, !P.COLOR specifies the color index.

For example, to draw using the color of entry 160 in the current color table, set

```
!P.COLOR=160
```

TrueColor Mode

Set this keyword to a hexadecimal 24-bit RGB color specification ('bbggrr'x). Note that IDL's Direct Graphics system uses a different specification format than the Object Graphics system.

For example to draw using a pure blue line, set

```
!P.COLOR='FF0000'x
```

PLOTS, POLYFILL, XYOUTS

When used with the PLOTS, POLYFILL, or XYOUTS procedure, this keyword parameter can be set to a vector to specify multiple color specifications.

Z-Buffer Graphics

Gouraud shading of polygons is performed with the Z-buffer graphics output device and POLYFILL procedure when COLOR contains an array of color specifications, one for each vertex.

DATA

Accepted by: [AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the data coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

DEVICE

[AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the device coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

For example, the following code displays an image contained in the variable A and then draws a contour plot of pixels [100:499, 100:399] over the correct section of the image:

```

;Display the image.
TV,A

;Draw the contour plot, specify the coordinates of the plot, in
;device coordinates, do not erase, set the X and Y axis styles to
;EXACT.
CONTOUR, A[100:499, 100:399], $
      POS = [100,100, 499,399], /DEVICE, $
      /NOERASE, XSTYLE=1, YSTYLE=1

```

Note that in the above example, the keyword specification /DEVICE is equivalent to DEVICE = 1.

FONT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#), [XYOUTS](#).
System variable equivalent: !P.FONT.

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to select the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See [Appendix H, “Fonts”](#) for a complete description of IDL’s font systems.

LINestyle

Accepted by: [DRAW_ROI](#), [Oplot](#), [PLOT](#), [PLOTS](#), [SURFACE](#). System variable equivalent: `!P.LINestyle`.

This keyword indicates the line style used to draw lines; it indicates the line style of the lines used to connect the data points. This keyword should be set to the appropriate index for the desired linestyle as described in the following table.

Index	Linestyle
0	Solid
1	Dotted
2	Dashed
3	Dash Dot
4	Dash Dot Dot
5	Long Dashes

Table B-22: IDL Linestyles

NOCLIP

Accepted by: [CONTOUR](#), [DRAW_ROI](#), [Oplot](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SURFACE](#), [XYOUTS](#). System variable equivalent: `!P.NOCLIP`.

Set this keyword to suppress clipping of the plot. The clipping rectangle is contained in `!P.CLIP`. By default, the plot is clipped within the plotting window.

Note

The default value is clipping-disabled for `PLOTS`, `POLYFILL`, and `XYOUTS`. For all other routines, the default is to enable clipping.

With `PLOTS`, `POLYFILL`, and `XYOUTS`, this keyword controls the clipping of vectors and vector-drawn text. The default is to disable clipping, so to enable clipping

include the parameter `NOCLIP = 0`. To explicitly disable clipping set this parameter to one.

NODATA

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#).

If this keyword is set, only the axes, titles, and annotation are drawn. No data points are plotted.

For example, to draw an empty set of axes between some given values:

```
PLOT, [XMIN, XMAX], [YMIN, YMAX], /NODATA
```

NOERASE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SURFACE](#). System variable equivalent: `!P.NOERASE`.

Specifies that the screen or page is not to be erased. By default, the screen is erased, or a new page is begun, before a plot is produced.

Warning

If the `NOERASE` keyword (or `!P.NOERASE`) is set, the value of the [BACKGROUND](#) keyword (or `!P.BACKGROUND`) is ignored.

NORMAL

Accepted by: [AXIS](#), [CONTOUR](#), [CURSOR](#), [DRAW_ROI](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [XYOUTS](#).

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the normalized coordinate system, and range from 0.0 to 1.0. The default coordinate system is `DATA` if no other coordinate-system specifications are present.

ORIENTATION

Accepted by: [DRAW_ROI](#), [POLYFILL](#), [XYOUTS](#).

Specifies the counterclockwise angle in degrees from horizontal of the text baseline and the lines used to fill polygons. When used with the `POLYFILL` procedure, this keyword forces the “linestyle” type of fill, rather than solid or patterned fill.

POSITION

Accepted by: [CONTOUR](#), [MAP_SET](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: !P.POSITION.

Allows direct specification of the plot window. POSITION is a 4-element vector giving, in order, the coordinates $[(X_0, Y_0), (X_1, Y_1)]$, of the lower left and upper right corners of the data window. Coordinates are expressed in normalized units ranging from 0.0 to 1.0, unless the DEVICE keyword is present, in which case they are in actual device units. The value of POSITION is never specified in data units, even if the DATA keyword is present.

When setting the position of the window, be sure to allow space for the annotation, which resides outside the window. IDL outputs the message “% Warning: Plot truncated.” if the plot region is larger than the screen or page size. The plot region is the rectangle enclosing the plot window and the annotation.

When plotting in three dimensions, the POSITION keyword is a 6-element vector with the first four elements describing, as above, the XY position, and with the last two elements giving the minimum and maximum Z coordinates. The Z specification is always in normalized coordinate units.

When making more than one plot per page it is more convenient to set !P.MULTI than to manipulate the position of the plot directly with the POSITION keyword.

For example, the following statement produces a contour plot with data plotted in only the upper left quarter of the screen:

```
CONTOUR, Z, POS=[0., 0.5, 0.5, 1.0]
```

Because no space on the left or top edges was allowed for the axes or their annotation, the above described warning message results.

See “[Specifying the Location of the Plot](#)” on page 1909 for more information.

Note

For information on window placement and multi-monitor configurations, see “[Multi-Monitor Configurations](#)” (*Using IDL*).

PSYM

Accepted by: [DRAW_ROI](#), [OPLOT](#), [PLOT](#), [PLOTS](#). System variable equivalent: !P.PSYM.

The symbol used to mark each data point. Normally, PSYM is 0, data points are connected by lines, and no symbols are drawn to mark the points. Set this keyword, or

the system variable !P.PSYM, to the symbol index as shown in the table below to mark data points with symbols. When a positive value is supplied for PSYM, no lines are used to connect the data points (except when PSYM=10). The keyword SYMSIZE is used to set the size of the symbols.

PSYM Value	Plotting Symbol
1	Plus sign (+)
2	Asterisk (*)
3	Period (.)
4	Diamond
5	Triangle
6	Square
7	X
8	User-defined. See USERSYM procedure.
9	Undefined
10	Histogram mode. Horizontal and vertical lines connect the plotted points, as opposed to the normal method of connecting points with straight lines. See “Histogram Mode” on page 5625 for an example.

Table B-23: Values for the PSYM Keyword

Negative values of PSYM cause the symbol designated by PSYM to be plotted at each point with solid lines connecting the symbols. For example, a value of -5 plots triangles at each data point and connects the points with lines. Histogram mode is the exception to this rule; since the points are already connected when PSYM=10, specifying the value -10 is meaningless, and will result in an error.

The following IDL code plots an array using points, and then overplots the smoothed array, connecting the points with lines:

```
;Plot using points.
PLOT, A, PSYM=3

;Overplot smoothed data.
OPLOT, SMOOTH(A,7)
```

See “Plotting Symbols” on page 1901 for another example.

Histogram Mode

Using the keyword PSYM=10 with the PLOT routines draws graphs in the histogram mode, connecting points with vertical and horizontal lines. This next figure illustrates the comparison between the distribution of the IDL normally distributed random number function (RANDOMN) to the theoretical normal distribution.

Figure B-9: Histogram Mode

The plot was produced by the following IDL commands:

```

; Two-hundred values ranging from -5 to 4.95:
X = FINDGEN(200) / 20. - 5.
; Theoretical normal distribution, scale so integral is one:
Y = 1/SQRT(2.*!PI) * EXP(-X^2/2) * (10./200)
; Approximate normal distribution with RANDOMN,
; then form the histogram.
H = HISTOGRAM(RANDOMN(SEED, 2000), $
BINSIZE = 0.4, MIN = -5., MAX = 5.)/2000.
; Plot the approximation using "histogram mode."
PLOT,FINDGEN(26) * 0.4 - 4.8, H, PSYM = 10
; Overplot the actual distribution:
OPLOT, X, Y * 8.

```

SUBTITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.SUBTITLE`.

A text string to be used as a subtitle for the plot. Subtitles appear below the X axis.

SYMSIZE

Accepted by: [DRAW_ROI](#), [OPLOTT](#), [PLOT](#), [PLOTS](#).

Specifies the size of the symbols drawn when `PSYM` is set. The default size of 1.0 produces symbols approximately the same size as a character.

T3D

Accepted by: [AXIS](#), [CONTOUR](#), [DRAW_ROI](#), [MAP_SET](#), [OPLOTT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#), [TV](#), [TVCRS](#), [TVSCL](#), [XYOUTS](#). System variable equivalent: `!P.T3D`.

Set this keyword to indicate that the generalized transformation matrix in `!P.T` is to be used. If not present, the user-supplied coordinates are simply scaled to screen coordinates. See the examples in the description of the `SAVE` keyword.

Note

Since `T3D` uses the transformation matrix in `!P.T`, it is important that `!P.T` contain a valid transformation matrix. This can be achieved in several ways:

- Use the `SAVE` keyword to save the transformation matrix from an earlier graphics operation.
- Establish a transformation matrix using the `T3D`, `SURFR`, or `SCALE3` procedures.
- Set the value of `!P.T` directly.

Note

When used with the `TV` or `TVSCL` routines, the `T3D` and `Z` keywords are only honored when the `DATA` keyword is also set. Note also that when the `T3D` keyword is set, the `X` and `Y` arguments and the `Z` keyword position the lower left corner of the image, but do not change its orientation. Use the [POLY_2D](#) routine to warp the image into 3D space.

THICK

Accepted by: [AXIS](#), [DRAW_ROI](#), [O PLOT](#), [PLOT](#), [PLOTS](#), [POLYFILL](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.THICK`.

Indicates the line thickness. `THICK` overrides the setting of `!P.THICK`.

TICKLEN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.TICKLEN`.

Controls the length of the axis tick marks, expressed as a fraction of the window size. The default value is 0.02. `TICKLEN` of 1.0 produces a grid, while a negative `TICKLEN` makes tick marks that extend outside the window, rather than inwards. A value of -0.02 makes tick marks that extend away from the plot. Individual axis ticks can be controlled with the [\[XYZ\]TICKLEN](#) keyword.

For example, to produce outward-going tick marks of the normal length:

```
PLOT, X, Y, TICKLEN = -0.02
```

To provide a new default tick length, set `!P.TICKLEN`.

TITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `!P.TITLE`.

Produces a main title centered above the plot window. The text size of this main title is larger than the other text by a factor of 1.25. For example:

```
PLOT, X, Y, TITLE = 'Final Results'
```

[XYZ]CHARSIZE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalents: `![XYZ].CHARSIZE`.

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor set by `!P.CHARSIZE` or the keyword `CHARSIZE`.

[XYZ]GRIDSTYLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#)

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See [LINESTYLE](#) for a list of linestyles.

[XYZ]MARGIN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].MARGIN.

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. The plot window is the rectangular area that contains the plot data, i.e. the area enclosed by the axes.

The default values for XMARGIN are [10, 3] yielding a 10-character wide left margin and a 3-character wide right margin. The values for YMARGIN are [4, 2], for a 4-character high bottom margin and a 2-character high top margin. While specifying ZMARGIN will not cause an error, Z margins are currently ignored.

[XYZ]MINOR

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].MINOR.

The number of minor tick mark intervals. If set to zero, the default, IDL automatically determines the number of minor ticks in each major tick-mark interval. Setting this value a positive, nonzero number, n , produces n minor-tick intervals, and $n-1$ minor-tick marks. Setting this value equal to 1 suppresses minor tick marks. (Set [\[XYZ\]TICKS=1](#) to suppress major tick marks.)

[XYZ]RANGE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].RANGE.

The desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. IDL will frequently round this range. This override can be defeated using the [XYZ]STYLE keywords.

See “[Range Keyword](#)” on page 1899 for an example.

[XYZ]STYLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].STYLE`.

This keyword allows specification of axis options such as rounding of tick values and selection of a box axis. Each option is described in the following table:

Value	Description
1	Force exact axis range.
2	Extend axis range.
4	Suppress entire axis
8	Suppress box style axis (i.e., draw axis on only one side of plot)
16	Inhibit setting the Y axis minimum value to 0 (Y axis only)

Table B-24: Values for the [XYZ]STYLE Keyword

Note that this keyword is set bitwise, so multiple effects can be achieved by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the XSTYLE keyword to 1+8, or 9.

[XYZ]THICK

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].THICK`.

This keyword controls the thickness of the lines forming the *x*, *y*, or *z* axes and their tick marks. A value of 1.0 is the default.

[XYZ]TICK_GET

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#).

A named variable in which to return the values of the tick marks for the designated axis. The result is a double precision floating-point array with the same number of elements as ticks.

For example, to retrieve in the variable *V* the values of the tick marks selected by IDL for the *Y* axis:

```
PLOT, X, Y, YTICK_GET = V
```

[XYZ]TICKFORMAT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKFORMAT`.

Set this keyword to a string or a vector of strings. The string can be a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels. If a vector is provided, each string corresponds to a level of the axis. The [\[XYZ\]TICKUNITS](#) keyword determines the number of levels for an axis.

Each string is one of the following:

A format code:

If the string begins with an open parenthesis, it is treated as a standard format string. See “[Format Codes](#)” (Chapter 18, *Application Programming*) for more information on format codes.

Example 1: Display the X axis tick values using a format of F6.2 (six characters, with 2 places after the decimal point):

```
PLOT, X, Y, XTICKFORMAT='(F6.2)'
```

Example 2: Display the Y tick values using the “dollars and cents” format \$ddd.dd:

```
PLOT, X, Y, YTICKFORMAT='("$", F7.2)'
```

The string 'LABEL_DATE' :

Set [XYZ]TICKFORMAT to the string 'LABEL_DATE' to create axes with date labels. The formatting of the labels is specified by first calling LABEL_DATE with the DATE_FORMAT keyword. See [LABEL_DATE](#) for more information.

Example: Use the LABEL_DATE function as the callback function to display the X tick values in a date/time format:

```
dummy = LABEL_DATE(DATE_FORMAT='%M %Z')
mytimes = TIMEGEN(12, UNITS='MONTHS', START=JULDAY(1,1,2000))
y = FINDGEN(12)
PLOT, mytimes, y, XTICKUNITS='Time', XTICKFORMAT='LABEL_DATE'
```

See the “Examples” section of [LABEL_DATE](#) for more extensive examples.

The name of a user-defined function:

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined

with either three or four parameters, depending on whether [XYZ]TICKUNITS is specified:

If [XYZ]TICKUNITS is *not* specified, the callback function is called with three parameters, *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis.
- *Index* is the tick mark index (indices start at 0).
- *Value* is the data value at the tick mark (a double-precision floating point value).

Note

Value is a double-precision floating-point value that represents the Julian date. The Julian date follows the astronomical convention, where Julian date 0.0d corresponds to 1 Jan 4713 B.C.E. at 12 pm.

If [XYZ]TICKUNITS is specified, the callback function is called with four parameters, *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled (level indices start at 0).

Example 1: Use a callback function to display the Y tick values as a percentage of a fixed value. Note that because we don't specify [XYZ]TICKUNITS, we do not include the *Level* parameter in our function definition:

```
FUNCTION YTICKS, axis, index, value
  fixvalue = 389.0d
  pvalue = (value/fixvalue) * 100.0d
  RETURN, STRING(pvalue, FORMAT='(D5.2, "%") ')
END

PRO use_callback
  Y = FINDGEN(10)
  PLOT, Y, YTICKFORMAT='YTICKS'
END
```

Example 2: Create a two-level X axis. Display the X tick values in a customized date/time format that shows the number of days open for business for each month on one level, and marks leap years with an asterisk on another level:

```
FUNCTION XTICKS, axis, index, value, level

  CASE level OF
```

```

0: BEGIN ; months
    ; Number of days open for business in given month:
    CALDAT, value, month
    open = [18,19,23,20,22,22,19,10,20,21,22,14]
    nbdays = open[month]
    ; Return a string containing the month name plus
    ; the number of business days in parentheses:
    RETURN, STRING(value, nbdays, $
        FORMAT='(C(CMoA), "(, I2, ")")')
    END
1: BEGIN ; years
    ; Generate a string for the year.
    yrStr = STRING(value, FORMAT='(C(CYI))')
    ; Determine if a leap year. If so,
    ; append an asterisk to the string.
    CALDAT, value, mo, da, yr
    IF (yr MOD 4 EQ 0) THEN BEGIN
        IF (yr MOD 100 EQ 0) THEN $
            isLeap = (yr MOD 400) EQ 0 $
        ELSE $
            isLeap = 1b
        ENDIF ELSE $
            isLeap = 0b
        IF (isLeap NE 0b) THEN $
            yrStr = yrStr + '*'
        RETURN, yrStr
    END
ENDCASE

END

PRO plot_sales

myDates = TIMEGEN(12, UNITS='Months', START=JULDAY(1,1,2000))
sales = [180,190,230,200,220,220,190,100,200,210,220,140]
PLOT, myDates, sales, XTICKUNITS=['Months', 'Years'], $
    XTICKFORMAT='XTICKS', XTITLE = 'Date (* = Leap Year)', $
    YTITLE='Sales (units)', POSITION = [0.2, 0.2, 0.9, 0.9]

END

```

[XYZ]TICKINTERVAL

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#)

variable equivalent: ![XYZ].[TICKINTERVAL](#)

Set this keyword to a scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis range ([XYZ]RANGE) and the number of major tick intervals ([XYZ]TICKS). This keyword takes precedence over [XYZ]TICKS.

For example, if TICKUNITS=["Seconds", "Hours", "Days"], and XTICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

[XYZ]TICKLAYOUT

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].TICKLAYOUT.

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

Note

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

[XYZ]TICKLEN

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: ![XYZ].TICKLEN.

This keyword controls the lengths of tick marks (expressed in normal coordinates) for the individual axes. This keyword, if nonzero, overrides the global tick length specified in !P.TICKLEN, and/or the [TICKLEN](#) keyword parameter, which is expressed as a fraction of the window size in the tick mark's direction.

[XYZ]TICKNAME

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKNAME`.

A string array of up to 30 elements that controls the annotation of each tick mark. If omitted or if a given string element contains the null string, IDL labels the tick mark with its value. To suppress the tick labels, supply a string array of one-character long, blank strings, i.e., `REPLICATE(' ', N)`. Null strings force IDL to number the tick mark with its value.

Note

If there are n tick-mark intervals, there are $n + 1$ tick marks and labels.

[XYZ]TICKS

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKS`.

The number of major tick *intervals* to draw for the axis. If this keyword is set to zero or omitted, IDL selects from three to six tick intervals. Setting this value to n , where $n > 1$, produces exactly n tick intervals, and $n+1$ tick marks. Setting this value equal to 1 suppresses major tick marks. (Set [\[XYZ\]MINOR=1](#) to suppress minor tick marks.)

[XYZ]TICKUNITS

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKUNITS`.

Set this keyword to a string or a vector of strings indicating the units to be used for axis tick labeling. If a vector of strings is provided, the axis will be drawn in multiple levels, where each string represents one level in the specified units.

Note

When creating multiple-level axes, you may need to adjust the plot positioning using the [POSITION](#) or [\[XYZ\]MARGIN](#) keywords in order to ensure that axis labels and titles are visible in the plot window.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- 'Numeric'
- 'Years'
- 'Months'
- 'Days'
- 'Hours'
- 'Minutes'
- 'Seconds'
- 'Time' - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- '' - Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the 'Numeric' unit. This is the default setting.

If any of the time units are utilized, the tick values are interpreted as Julian date/time values.

Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

Note

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

[XYZ]TICKV

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TICKV`.

The data values for each tick mark, an array of up to 60 elements. You can directly specify these values, producing graphs with arbitrary tick marks. If you do this, IDL scales the axis from the first tick value to the last unless you directly specify a range.

Note

To specify the number of ticks and their values exactly, set `[XYZ]TICKS=N` (where $N > 1$) and `[XYZ]TICKV=Values`, where *Values* has $N+1$ elements.

[XYZ]TITLE

Accepted by: [AXIS](#), [CONTOUR](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#). System variable equivalent: `![XYZ].TITLE`.

A string that contains a title for the specified axis.

Z

Accepted by: [PLOTS](#), [POLYFILL](#), [TV](#), [TVCRS](#), [TVSCL](#), [XYOUTS](#).

Provides the Z coordinate if a Z parameter is not present in the call. This is of use only if the three-dimensional transformation is in effect (i.e., the T3D keyword is set).

ZVALUE

Accepted by: [AXIS](#), [CONTOUR](#), [MAP_SET](#), [OPLOT](#), [PLOT](#), [SHADE_SURF](#), [SURFACE](#).

Sets the Z coordinate, in normalized coordinates in the range of 0 to 1, of the axis and data output from [PLOT](#), [OPLOT](#), and [CONTOUR](#).

This keyword has effect only if `!P.T3D` is set and the three-dimensional to two-dimensional transformation is stored in `!P.T`. If `ZVALUE` is not specified, [CONTOUR](#) will output each contour at its Z coordinate, and the axes and title at a Z coordinate of 0.0.

Appendix C

Thread Pool Keywords

Many of the system routines documented in this manual make use of the IDL thread pool. The thread pool is discussed in detail in [Chapter 10, “Multithreading in IDL”](#) (*Application Programming*). System-wide use of the thread pool can be controlled with the `CPU` procedure, and the current system settings are visible via the `!CPU` system variable.

All system routines that use the thread pool accept the following keywords, which can be used to modify the default behavior for the duration of a single call. This allows you to modify the settings for a particular computation without affecting the global default settings of the IDL session.

Thread Pool Keywords

TPOOL_MAX_ELTS

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number you specify, IDL will not use the thread pool for the

computation. Setting this value to 0 removes any limit on the maximum number of elements, and any computation with at least `TPOOL_MIN_ELTS` will use the thread pool.

This keyword overrides the default value, given by `!CPU.TPOOL_MAX_ELTS`. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) (Chapter 10, *Application Programming*) for discussion of the circumstances under which it may be useful to specify a maximum number of elements.

TPOOL_MIN_ELTS

Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number you specify, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

This keyword overrides the default value, given by `!CPU.TPOOL_MIN_ELTS`. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) (Chapter 10, *Application Programming*) for discussion of the circumstances under which it may be useful to specify a minimum number of elements.

TPOOL_NOTHREAD

Set this keyword to explicitly prevent IDL from using the thread pool for the current computation. If this keyword is set, IDL will use the non-threaded implementation of the routine even if the current settings of the `!CPU` system variable would allow use of the threaded implementation.

This keyword overrides the default value, given by `!CPU.TPOOL_NTHREADS`. See [“Possible Drawbacks to the Use of the IDL Thread Pool”](#) (Chapter 10, *Application Programming*) for discussion of the circumstances under which it may be useful to disable use of the thread pool entirely.

Appendix D

System Variables

The following topics are included in this appendix:

What Are System Variables?	5640	IDL Environment System Variables	5652
Constant System Variables	5642	Graphics System Variables	5664
Error Handling System Variables	5646		

What Are System Variables?

System variables are a special class of predefined variables available to all program units. Their names always begin with the exclamation mark character (!). System variables are used to set the options for plotting, to set various internal modes, to return error status, etc.

System variables have a predefined type and structure that cannot be changed. When an expression is stored into a system variable, it is converted to the variable type, if necessary and possible.

Changing the Value of a System Variable

Some system variables are *read-only*: they contain values that are static and cannot or should not be changed by the user. For example, the value of the system variable `!PI` always contains the single-precision value of pi (π), which is not available for redefinition.

You can change most system variables, however, simply by assigning a new value to the variable. For example, to change the current value of the `!PROMPT` system variable, which contains the text string used by IDL to prompt the user for input, simply assign a new string:

```
!PROMPT = "My IDL: "
```

This change will persist for the duration of the IDL session or until you make a new assignment.

Some system variables take their values from a *preference*. Changing the value of the associated preference changes the value of the system variable (although in some cases the change will not take effect until IDL is restarted). Preference values persist between IDL sessions; your change will stay in effect until you either change the preference value or assign a new value to the system variable directly. For additional information on preferences, see [Appendix E, "IDL System Preferences"](#).

Finally, you can define new system variables using the `DEFSYSV` procedure.

Default Values of System Variables

Each system variable takes its default value from one of the following sources:

- IDL's internal defaults. You cannot modify the default values of these system variables. The values of these system variables are either fixed (the value of `!PI`, for example) or must be generated by IDL depending on the current state (like the value of `!ERROR_STATE`).
- A user or system preference. You can modify the default values of these system variables by modifying the value of its associated preference. System variables with associated preferences are noted in the following sections.

Constant System Variables

The following system variables contain predefined constants or values for use by IDL routines. System variables can be used just like other variables. For example, the command:

```
PRINT, ACOS(A) * !RADEG
```

converts a result expressed in radians to one expressed in degrees.

!DPI

A read-only variable containing the double-precision value of pi (π).

!DTOR

A read-only variable containing the floating-point value used to convert degrees to radians ($\pi/180 \cong 0.01745$).

!MAP

A variable containing the information needed to effect coordinate conversions between points of latitude and longitude and map coordinates. The values in this structure are established by the MAP_SET procedure; the user should not change them directly.

The !MAP structure contains the following fields:

A

A double-precision floating point integer specifying the equatorial radius or semimajor axis in meters. (The default is 6370997 m.)

COSO

A double-precision floating point integer specifying the cosine of the center latitude in degrees.

COSR

A double-precision floating point integer specifying the cosine of the rotation angle.

E2

A double-precision floating point integer specifying the eccentricity squared of the ellipsoid.

FILL_METHOD

A long-integer variable that indicates the fill order. True (1) fills counterclockwise, False (0) fills starting with the closest polygons.

LL_BOX

A four-element, double-precision floating point array that specifies the map range in degrees (latmin, lonmin, latmax, lonmax).

P

A 16-element, double-precision floating point array indicating additional projection parameters.

P0LAT

A double-precision floating point integer specifying the center latitude in degrees.

P0LON

A double-precision floating point integer specifying the center longitude in degrees.

PIPELINE

A four by four, double-precision floating point array specifying the graphics clipping and splitting pipeline.

POLE

A seven-element, double-precision floating point array that indicates Pole location parameters. Longitude and latitude are given in radians, sine and cosine of polar latitude, and X,Y,Z coordinates.

PROJECTION

A long-integer variable indicating the projection number (for GCTP only).

ROTATION

A double-precision floating point integer specifying the rotation angle in degrees, clockwise of pole.

SEGMENT_LENGTH

A double-precision floating point integer specifying the maximum segment length.

SIMPLE

A long-integer variable indicating the projection number. For IDL projections, True (1) indicates the projection is centered on the Equator or no rotation. For GCTP, this number is the GCTP projection number.

SINO

A double-precision floating point integer specifying the sine of the center latitude.

SINR

A double-precision floating point integer specifying the sine of the rotation angle.

U0

A double-precision floating point integer specifying the center longitude in radians.

UP_FLAGS

A double-precision floating point integer that sets the user projection flags (currently unused).

UP_NAME

A string that specifies the projection name (used only for GCTP).

UV

A two-element, double-precision floating point array specifying the U,V coordinates of the last point.

UV_BOX

A four-element, double-precision floating point array that contains the map range in meters (xmin, ymin, xmax, ymax).

V0

A double-precision floating point integer specifying the center latitude in radians.

!PI

A read-only variable containing the single-precision value of pi (π).

!RADEG

A read-only variable containing the floating-point value used to convert radians to degrees ($180/\pi \cong 57.2958$).

!VALUES

A read-only variable containing the IEEE single- and double-precision floating-point values *Infinity* and *NaN* (Not A Number). !VALUES is a structure variable with the following fields:

```
** Structure !VALUES, 4 tags, length=24:
   F_INFINITY      FLOAT      Infinity
   F_NAN           FLOAT      NaN
   D_INFINITY      DOUBLE     Infinity
   D_NAN           DOUBLE     NaN
```

where the meaning of the fields as follows:

F_INFINITY

The single-precision floating point value *Infinity*.

F_NAN

The single-precision floating point value *NaN* (Not a Number).

D_INFINITY

The double-precision floating point value *Infinity*.

D_NAN

The double-precision floating point value *NaN* (Not a Number).

For more information on these special floating-point values, see [“Special Floating-Point Values”](#) (Chapter 8, *Application Programming*).

Error Handling System Variables

The following system variables are either set by IDL when an error condition occurs or used by IDL when displaying information about errors.

!ERR

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the `!ERR` system variable will continue to function as before, but all new code should use `!ERROR_STATE.CODE`.

!ERROR_STATE

A structure variable which contains the status of the last error message. Whenever an error occurs, IDL sets the fields in this system variable according to the nature of the field. An IDL error is always comprised of an IDL-generated component, and may also contain an operating system-generated component. `!ERROR_STATE` includes the following fields:

```

** Structure !ERROR_STATE, 8 tags, length=112, data length=108:
NAME                STRING      'IDL_M_SUCCESS'
BLOCK               STRING      'IDL_MBLK_CORE'
CODE                LONG          0
SYS_CODE            LONG          Array[2]
SYS_CODE_TYPE       STRING      ''
MSG                 STRING      ''
SYS_MSG             STRING      ''
MSG_PREFIX          STRING      '% '

```

where the meaning of the fields as follows:

NAME

A read-only string variable containing the error name of the IDL-generated component of the last error message. Although the error code—as defined below in `CODE`—may change between IDL versions, the name will always remain the same. If an error has not occurred in the current IDL session, this field is set to `IDL_M_SUCCESS`.

BLOCK

A read-only string variable containing the name of the message block for the IDL-generated component of the last error message. If an error has not occurred in the current IDL session, this field is set to `IDL_MBLK_CORE`.

Note

See the *External Development Guide* for more information about blocks.

CODE

The error code of the IDL-generated component of the last error in IDL. Whenever an error occurs, IDL sets this system variable to the error code (a negative integer number) of the error. Although the error code may change between IDL versions, the name—as defined above in `NAME`—will always remain the same. If an error has not occurred in the current IDL session, this field is set to 0.

SYS_CODE

A long-integer variable containing the error code of the last error's operating system-generated component, if it exists.

For historical reasons, `SYS_CODE` is a two-element longword array. The first element of the array (that is, `SYS_CODE[0]`) contains the OS-defined error code. The second element of the array is not used, and always contains zero. Either `!ERROR_STATE.SYS_CODE` or `!ERROR_STATE.SYS_CODE[0]` will return the relevant error code.

SYS_CODE_TYPE

A string describing the type of system code contained in `SYS_CODE`. A null string in this field indicates that there is no system code corresponding to the current error. The possible non-NULL values are:

Value	Meaning
errno	Unix/Posix system error
win32	Microsoft Windows Win32 system error
winsock	Microsoft Windows sockets library error

Table D-25: `SYS_CODE_TYPE` Values

MSG

A read-only string variable containing the text of the last IDL-generated error message. Whenever an error occurs, IDL sets this field to the error message (a scalar string) that corresponds to the error code. If an error has not occurred in the current IDL session, this field is set to the null string, ''.

SYS_MSG

A read-only string variable containing the text of the last error's operating system-generated component, if it exists. When an operating system error occurs, IDL sets this field to the OS-defined error message string. If an error has not occurred in the current IDL session, this field is set to the null string, ''.

MSG_PREFIX

A string variable containing the prefix string used for the IDL-generated component of error messages. This field takes its default value from a *preference*. See “[IDL_MSG_PREFIX](#)” on page 5695 for details.

This system variable replaces !ERROR, !ERR_STRING, !MSG_PREFIX, !SYSERR_STRING, and !SYSERROR, and includes two new fields: error name and block name.

Using !ERROR_STATE

At the beginning of an IDL session, !ERROR_STATE contains default information. To see this information, you can either view !ERROR_STATE from the System field of the Variable Watch Window (see “[The Variables View](#)” (Chapter 8, *Application Programming*)) or you can enter PRINT, !ERROR_STATE at the Command Line. After an error has occurred, all of the fields of !ERROR_STATE display their updated status.

You can use MESSAGE, /RESET to reset all the fields in !ERROR_STATE to their default values.

!ERROR

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the !ERROR system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.CODE.

!ERR_STRING

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the !ERR_STRING system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.MSG.

!EXCEPT

An integer variable that controls when IDL checks for invalid mathematical computations (exceptions), such as division by zero. The three allowed values are:

0	Never report exceptions.
1	Report exceptions when the interpreter is returning to an interactive prompt (the default).
2	Report exceptions at the end of each IDL statement. Note that this slows IDL by roughly 5% compared to setting !EXCEPT=1.

For more information on invalid mathematical computations and error reporting, see “[Math Errors](#)” (Chapter 8, *Application Programming*).

The value of !EXCEPT is used by the CHECK_MATH function to determine when to return errors. See “[CHECK_MATH](#)” on page 265 for details.

Note

In versions of IDL up to and including IDL 4.0.1, the default exception handling was functionally identical to setting !EXCEPT=2.

!EXCEPT takes its default value from a *preference*. See “[IDL_EXCEPT](#)” on page 5694 for details.

!MOUSE

A structure variable that contains the status from the last cursor read operation. !MOUSE has the following fields:

```
** Structure !MOUSE, 4 tags, length=16:
  X             LONG             511
  Y             LONG             252
  BUTTON       LONG              4
  TIME         LONG             1428829775
```

where the meaning of the fields are described in the following sections.

X

Contains the X location (in device coordinates) of the cursor when the mouse button was pressed.

Y

Contains the Y location (in device coordinates) of the cursor when the mouse button was pressed.

BUTTON

Contains:

- 1 (one) if the left mouse button was pressed,
- 2 (two) if the middle mouse button was pressed
- 4 (four) if the right mouse button was pressed.

TIME

Contains the number of milliseconds since a base time.

See “[CURSOR](#)” on page 446 for details on reading the cursor position.

!MSG_PREFIX

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the [!MSG_PREFIX](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR_STATE.MSG_PREFIX](#).

!SYSERROR

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the [!SYSERROR](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR_STATE.SYS_CODE](#).

!SYSERR_STRING

This system variable is now obsolete and has been replaced by the [!ERROR_STATE](#) system variable. Code that uses the [!SYSERR_STRING](#) system variable will continue to function as before, but we suggest that all new code use [!ERROR_STATE.SYS_MSG](#).

!WARN

A structure variable that causes IDL to print warnings to the console or command log when obsolete IDL features are found at compile time. !WARN has the following fields:

```
** Structure !WARN, 3 tags, length=3:
OBS_ROUTINES      BYTE      0
OBS_SYSVARS       BYTE      0
PARENS            BYTE      0
```

where the meaning of the fields as follows:

OBS_ROUTINES

If this field is set to 1 (one), IDL generates warnings when it encounters references to obsolete internal or library routines.

OBS_SYSVARS

If this field is set to 1 (one), IDL generates warnings when it encounters references to obsolete system variables.

PARENS

If this field is set to 1 (one), IDL generates warnings when it encounters a use of parentheses to specify an index into an array.

Note

No warnings are generated when the fields of the !WARN structure are set equal to zero (the default).

IDL Environment System Variables

The following system variables contain information about IDL's configuration.

!CPU

IDL can use multiple system processors to perform some computations in parallel. See [Chapter 10, “Multithreading in IDL”](#) (*Application Programming*) for additional information.

The !CPU system variable supplies information about the state of the system processor, and of IDL's use of it. !CPU is readonly, and cannot be modified directly. Use the CPU procedure to modify values contained in !CPU.

The !CPU structure is defined as follows:

```
{ !CPU, HW_VECTOR:0L, VECTOR_ENABLE:0L, HW_NCPU:0L,
  TPOOL_NTHREADS:0L, TPOOL_MIN_ELTS:0L, TPOOL_MAX_ELTS:0L }
```

where the meaning of the fields as follows:

HW_VECTOR

True (1) if the system supports a vector unit (*e.g.*, Macintosh Altivec/Velocity Engine). False (0) otherwise.

Note

This value is currently always 0 (False) on platforms other than Macintosh.

VECTOR_ENABLE

True (1) if IDL will use a vector unit, if such a unit is available on the current system, and False (0) otherwise.

Note

This value is currently always 0 (False) on platforms other than Macintosh.

HW_NCPU

The number of CPUs contained in the system on which IDL is currently running.

TPOOL_NTHREADS

The number of threads that IDL will use in thread pool computations. The default is to use HW_NCPU threads, so that each thread will have the potential to run in parallel with the others. For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to using fewer CPUs.

If the IDL_CPU_TPOOL_NTHREADS preference has been set, then TPOOL_NTHREADS is initialized with this value at startup. On systems shared by multiple users, you may wish to set this preference so that IDL uses the specified number of threads instead of defaulting to the number of CPUs present in the underlying hardware. See [!CPU Settings Preferences](#) in [Appendix E, “IDL System Preferences”](#) for details.

TPOOL_MIN_ELTS

The number of elements in a computation that are necessary before IDL will use the thread pool to perform the work. For fewer than TPOOL_MIN_ELTS, the main IDL thread will simply perform the work without using the thread pool. It is important not to use the thread pool for small tasks because the overhead of threading will not be offset by the overhead incurred by operation of the pool, and the overall computation will go slower than if threading is not used.

TPOOL_MAX_ELTS

The maximum number of elements in a computation for which IDL will use the thread pool. If this value is 0 (zero) (the default), then no limit is imposed and any computation with at least TPOOL_MIN_ELTS is a candidate for the thread pool. If your computation is too large for the physical memory available on the system, the virtual memory system of the operating system will begin paging. Under such conditions, the performance of the thread pool can be worse than that of a single threaded computation because the threads end up fighting each other for access to memory. TPOOL_MAX_ELTS can be used to prevent this.

Note

The TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, TPOOL_NTHREADS, and VECTOR_ENABLE fields of this system variable take their default values from the [!CPU Settings Preferences](#). See [Appendix E, “IDL System Preferences”](#) for details.

!DIR

A string variable containing the path to the main IDL directory.

!DIR takes its default value from a *preference*. See “[IDL_DIR](#)” on page 5697 for details.

!DLM_PATH

Significant portions of IDL’s built in functionality are packaged in the form of Dynamically Loadable Modules (DLMs). DLMs correspond to UNIX sharable libraries or Windows DLLs, depending on the operating system in use. At startup, IDL searches for DLM definition files (which end in the `.d1m` suffix) and makes note of the routines supplied by each DLM. If such a routine is called, IDL loads the DLM that supplies it into memory. To see a list of the DLMs that IDL knows about, use `HELP, /DLM` (see “[HELP](#)” on page 994 for more information).

!DLM_PATH takes its default value from a *preference*. See “[IDL_DLM_PATH](#)” on page 5697 for details.

If the `IDL_DLM_PATH` preference is not explicitly defined by the user, IDL supplies a default that contains the directory in the IDL distribution where the supplied DLMs reside. Once `!DLM_PATH` is expanded, IDL uses it as the list of places to look for DLM definition files.

Since all DLM searching happens once at startup time, it would be meaningless to change the value of `!DLM_PATH` afterwards. For this reason, it is a read-only system variable and cannot be assigned to. The value of `!DLM_PATH` is useful because it shows you where IDL looked for DLMs when it started.

Using Path Definition Tokens to Load a DLM Path

Using the `<IDL_BIN_DIRNAME>` token in the `IDL_DLM_PATH` preference can be useful for distributing packages of DLMs with support for multiple operating system and hardware combinations. This token is described in “[The Path Definition String](#)” under [EXPAND_PATH](#).

For example, assume that you have your DLMs installed in `/usr/local/myd1m`, with support for each platform in a subdirectory using the same naming convention that IDL uses for the platform dependent subdirectories underneath the `bin` directory of the IDL distribution. Setting the `IDL_DLM_PATH` preference to the following:

```
" /usr/local/myd1m/<IDL_BIN_DIRNAME> : <IDL_DEFAULT> "
```

adds the location of the proper DLM for your current system to IDL's `!DLM_PATH` at startup.

Similarly, the `<IDL_VERSION_DIRNAME>` token can be useful for distributing packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms. This token is described in “[The Path Definition String](#)” under [EXPAND_PATH](#).

For example, assume that you have your DLMs installed in `/usr/local/mydmlm`. You create a subdirectory for each supported version of IDL within the `mydmlm` directory. Within each of those subdirectories would be a subdirectory for each operating system and hardware combination supported by that version of IDL. Setting the `IDL_DLM_PATH` preference to the following:

```
"/usr/local/mydmlm/<IDL_VERSION_DIRNAME>/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

adds the location of the proper DLM for your current system to IDL's `!DLM_PATH` at startup.

!EDIT_INPUT

This system variable determines whether or not the tty-based (non-IDE) command-line version of IDL does command-line editing when reading commands. The default value for `!EDIT_INPUT` comes from the [IDL_EDIT_INPUT](#) preference. See [Appendix E, “IDL System Preferences”](#) for details.

By default, IDL saves the last 20 command lines in a recall buffer. You can change the number of command lines saved in the recall buffer by setting the [IDL_RBUF_SIZE](#) preference to the desired number. To preserve backward compatibility with releases of IDL prior to version 6.2, you can also change the number of command lines saved in the recall buffer by setting `!EDIT_INPUT` equal to the number of lines you would like to save. In order for the change to take effect, IDL must be able to process the assignment statement before providing a command prompt. This means that you must put the assignment statement in the IDL startup file. (See “[Startup File](#)” (Chapter 1, *Using IDL*) for more information on startup files.)

To understand how IDL processes the request to change the recall buffer's size (either through `IDL_RBUF_SIZE` or through `!EDIT_INPUT`), see “[Support for Obsolete Preference Mechanisms](#)” on page 5714.

!HELP_PATH

A string variable listing the directories IDL will search for online help files. Help files must either be part of an IDL Assistant online help system (controlled by a `.adp`

file), Adobe Portable Document Format (.pdf) files, or HTML (.html or .htm) files. On Windows systems, help files can also be HTML Help (.chm) or Windows Help (.hlp) files. See [Chapter 22, “Providing Online Help For Your Application”](#) (*Application Programming*) for additional information on creating IDL Assistant online help systems or other online help files.

!HELP_PATH takes its default value from a *preference*. See [“IDL_HELP_PATH”](#) on page 5698 for details.

If the IDL_HELP_PATH preference is not explicitly defined by the user, IDL supplies a default that contains the directory in the IDL distribution where the supplied help files reside.

To change the value of !HELP_PATH for the duration of an IDL session, simply set the variable equal to a new string containing the desired path. See [“Changing the Value of !PATH After IDL Starts”](#) on page 5659 for tips that also apply to setting the value of !HELP_PATH.

!JOURNAL

A read-only long-integer variable containing the logical unit number of the file used for journal output.

!MAKE_DLL

The MAKE_DLL procedure and the CALL_EXTERNAL function’s AUTO_GLUE keyword use the standard system C compiler and linker to generate sharable libraries that can be used by IDL in various contexts (CALL_EXTERNAL, DLMS, LINKIMAGE). There is a great deal of variation possible in the use of these tools between different platforms, operating system versions, and compiler releases. The !MAKE_DLL system variable is used to configure how IDL uses them for the current platform.

The !MAKE_DLL structure is defined as follows:

```
{ !MAKE_DLL, COMPILE_DIRECTORY:'', COMPILER_NAME:'', CC:'', LD:'' }
```

where the meaning of the fields as follows:

COMPILE_DIRECTORY

IDL requires a place to create the intermediate files necessary to build a sharable library, and possibly the final library itself. Unless told to use an explicit directory, it uses the directory given by the COMPILE_DIRECTORY field of !MAKE_DLL.

IDL takes the default value of this field from a *preference*. See “[IDL_MAKE_DLL_COMPILE_DIRECTORY](#)” on page 5698 for details.

COMPILER_NAME

A string containing the name of the C compiler used to build the currently running IDL. This field is not used by IDL, and exists solely for informational purposes and to help the end user decide which C compiler to install on their system.

CC

A string used by IDL as a template to construct the command for using the C compiler. This template uses PRINTF style substitution codes, as described in the following table.

LD

A string used by IDL as a template to construct the command for using the linker. This template uses PRINTF style substitution codes, as described in the following table.

When expanding !MAKE_DLL.CC and !MAKE_DLL.LD, IDL substitutes text in place of the PRINTF style codes described in [Table D-26](#). These codes are case-insensitive (they can be either upper or lower case).

Note

It is possible to use C compilers other than the one assumed in !MAKE_DLL to build sharable libraries. To do so, you can alter the contents of !MAKE_DLL or use the CC and/or LD keyword to MAKE_DLL and CALL_EXTERNAL. Please understand that a list of all possible compilers and the necessary compiler options is not maintained. This information is available in your compiler and system documentation. It is the programmer’s responsibility to understand the rules for the chosen compiler.

The following table describes the substitution codes for the CC and LD fields:

Code	Meaning
%B %b	The base name of a C file to compile. For example, if the C file is <code>moose.c</code> , then %B substitutes <code>moose</code> .
%C %c	The name of the C file.

Table D-26: Description of CC and LD Field Codes

Code	Meaning
%E %e	The name of the linker options file. This file, which is automatically generated by IDL as needed, is used to control the linker. Under UNIX, the system documentation refers to this as an export file, or a linker map file. Microsoft Windows calls it a <code>.DEF</code> file.
%F %f	This substitution code is no longer meaningful, and will be ignored.
%L %l	The name of the resulting sharable library. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (<code>.dll</code> , <code>.so</code> , <code>.sl</code> , <code>.exe</code> , <i>etc.</i>).
%O %o	An object file name. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (<code>.o</code> , <code>.obj</code>).
%X %x	When expanding <code>!MAKE_DLL.CC</code> , IDL inserts any text supplied via the <code>EXTRA_CFLAGS</code> keyword to <code>MAKE_DLL</code> or <code>CALL_EXTERNAL</code> in place of %X. IDL does not interpret this text. It is the user's responsibility to ensure that it is meaningful in the command. When expanding <code>!MAKE_DLL.LD</code> , the text from the <code>EXTRA_LFLAGS</code> keyword is substituted. The primary use for this code is to include necessary header include directories and link libraries.
%%	Replaced with a single % character.

Table D-26: Description of CC and LD Field Codes (Continued)

!MORE

An integer variable indicating whether IDL should paginate help output sent to a tty device. (This preference has no effect on the IDL Workbench Console view.) Setting `!MORE` to zero (0) prevents IDL from paginating the output text. A non-zero value (the default) causes IDL to display output text one screen at a time.

`!MORE` takes its default value from a *preference*. See “[IDL_MORE](#)” on page 5694 for details.

!PATH

A string variable listing the directories IDL will search for libraries and include files.

Note

The current directory is always searched before consulting !PATH.

!PATH takes its default value from a *preference*. See “[IDL_PATH](#)” on page 5699 for details.

If you are using the IDL Workbench, your project directories may be added to !PATH. See [IDL Path Management](#) for additional information.

Note on Path Expansion

When IDL starts, it reads the value of the IDL_PATH preference and builds a value to be stored in !PATH from the specified initialization value. While the initialization value can consist of a normal path string specifying all directories to be included in !PATH, it can also take advantage of several special values that IDL uses to dynamically create the value of !PATH. These values (the “+” symbol and the “<IDL_*>” strings) are described in detail in “[The Path Definition String](#)” under “[EXPAND_PATH](#)” (*IDL Reference Guide*).

Path Caching

By default, as IDL searches directories included in the !PATH system variable for .pro or .sav files to compile, it creates an in-memory list of *all* .pro and .sav files contained in each directory. When IDL later searches for a .pro or .sav file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process. If use of the patch cache causes problems, you can disable it either via a keyword to the PATH_CACHE routine or via the [IDL_PATH_CACHE_DISABLE](#) preference.

See “[PATH_CACHE](#)” (*IDL Reference Guide*) for details.

Changing the Value of !PATH After IDL Starts

Once IDL has started, you can alter the value of !PATH by setting it to a new string value. For example, on a UNIX system, to add a directory to !PATH for the duration of an IDL session, you would use a command like the following:

```
!PATH = '/usr2/project/idl_files:' + !PATH
```

Keep the following in mind when changing the value of `!PATH` by setting its value to a new string:

- Remember to use the proper platform-specific directory separator character in path specification strings.
- Remember to use the proper path string separator character for your platform. If you are writing a cross-platform application that changes `!PATH`, you may want to use code that looks something like this:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = 'new_path' + pathsep + !PATH
```

where *new_path* is the path to the directory you want to add.

- You can use the `EXPAND_PATH` function to generate a path string. This method allows you to specify one or more directories and let IDL figure out whether those directories contain `.pro` or `.sav` files. It also allows you to use the “+” character path expansion technique. For example, the following commands add all directories below the *new_path* directory that contain `.pro` or `.sav` files to `!PATH`:

```
pathsep = PATH_SEP(/SEARCH_PATH)
!PATH = EXPAND_PATH('+new_path') + pathsep + !PATH
```

See “[EXPAND_PATH](#)” (*IDL Reference Guide*) for details.

- Setting the value of `!PATH` within an IDL session changes the value for that session only. If you want to change the value permanently, change the value of the `IDL_PATH` preference, using either the [PREF_SET](#) command or the Preferences dialog of the workbench.

!PROMPT

A string variable containing the text string used by IDL to prompt the user for input. The default is `IDL>`.

`!PROMPT` takes its default value from a *preference*. See “[IDL_PROMPT](#)” on page 5695 for details.

!QUIET

A long-integer variable indicating whether informational messages should be printed (0) or suppressed (nonzero). By default, `!QUIET` is set to zero.

!QUIET takes its default value from a *preference*. See “IDL_QUIET” on page 5695 for details.

!VERSION

A structure variable containing information about the version of IDL in use. The structure is defined as follows:

```
{ !VERSION, ARCH:'', OS:'', OS_FAMILY:'', OS_NAME:'', $
  RELEASE:'', BUILD_DATE:'', MEMORY_BITS:0, FILE_OFFSET_BITS:0 }
```

where the meaning of the fields as follows:

ARCH

CPU hardware architecture of the system. The ARCH field will report one of the following strings, depending on the operating system and number of bits used to address memory:

Operating System	Memory Bits	Value of ARCH field
Windows	32	x86
	64	x86_64
Macintosh OS X (PowerPC)	32	ppc
Macintosh OS X (Intel)	32	i386
	64	x86_64
Linux	32	x86
	64	x86_64
Solaris	32	sparc
	64	sparc

OS

The vendor name of the operating system. The OS field will report one of the following strings: linux, darwin, sunos, Win32. This is the name of the underlying operating system kernel (not necessarily of the overall operating environment: see OS_NAME). Once an OS name is assigned to a platform, it is not altered in subsequent releases. This makes it safe for use in IDL programs that need to distinguish between platforms. Consider using the OS_FAMILY field before using

the OS field, as most programs are mainly concerned with high level platform differences.

OS_FAMILY

The generic name of the operating system (UNIX, Windows). Whenever possible, use this field (rather than OS or OS_NAME) in code that must distinguish between platforms.

OS_NAME

The vendor's name for the operating system environment, as used by the vendor for casual descriptive and promotional purposes. For example, on Sun workstations, the name of the operating system kernel (!VERSION.OS) is "sunos", whereas the name of the overall system (!VERSION.OS_NAME) is "Solaris". Vendors change their descriptive environment names from time to time, and the OS_NAME field is updated to reflect this. As a result, restrict your use of this field to descriptive textual uses, and use the OS_FAMILY or OS fields of !VERSION in code that must distinguish between platforms.

RELEASE

IDL version number.

BUILD_DATE

The date the IDL executable was compiled, in the format dictated by ANSI C for the `__DATE__` macro.

MEMORY_BITS

The number of bits used to address memory. Possible values are 32 or 64. The number of bits used to address memory places a theoretical upper limit on the amount of memory available to IDL.

FILE_OFFSET_BITS

The number of bits used to position file offsets. Possible values are 32 or 64. The number of bits used to position files places a theoretical upper limit on the largest file IDL can access.

Note

If you need to differentiate between different IDL versions in your code, use `!VERSION.OS_FAMILY`. At present, two operating system families are supported: UNIX and Windows. For even more detail, you can use `!VERSION.OS`.

Graphics System Variables

The following system variables control various IDL Direct Graphics functions. These system variables are structures that contain many tags. For example, the command

```
!P.TITLE = 'Cross Section'
```

sets the default plot title.

Many of the functions of the graphics keywords described in [Appendix B, “Graphics Keywords”](#), are also controlled by the system variables !P, !X, !Y, and !Z.

You can change the default style of plots, fonts, etc., by setting the corresponding field in the appropriate system variable. Also, some effects that persist longer than one call are controlled only by system variables. The field !P.MULTI is one example.

Two-Dimensional Coordinate Conversion

The system variables !D, !P, !X, !Y, and !Z contain the information necessary to convert from one coordinate system to another. The relevant fields of these system variables are explained below, and formulae are given for conversions to and from each coordinate system. See [“Coordinates of 3-D Graphics”](#) (Chapter 5, *Using IDL*) for a discussion of three-dimensional coordinates.

In the following discussion, D is a data coordinate, N is a normalized coordinate, and R is a raw device coordinate.

The fields !D.X_VSIZE and !D.Y_VSIZE always contain the size of the visible area of the currently selected display or drawing surface. Let V_x and V_y represent these two sizes.

The field !X.S is a two-element array that contains the parameters of the linear equation, converting data coordinates to normalized coordinates. !X.S[0] is the intercept, and !X.S[1] is the slope. !X.TYPE is 0 for a linear x -axis and 1 for a logarithmic x -axis. The y - and z -axes are handled in the same manner, using the system variables !Y and !Z.

Also, let D_x be the data coordinate, N_x the normalized coordinate, R_x the device coordinate, V_x the device X size (in device coordinates), and $X_i = !X.S_i$ (the scaling parameter).

With the above variables defined, the linear two-dimensional coordinate conversions for the x coordinate can be written as follows:

Coordinate Conversion	Linear	Logarithmic
Data to normal	$N_x = X_0 + X_1 D_x$	$N_x = X_0 + X_1 \log D_x$
Data to device	$R_x = V_x(X_0 + X_1 D_x)$	$R_x = V_x(X_0 + X_1 \log D_x)$
Normal to device	$R_x = N_x V_x$	$R_x = N_x V_x$
Normal to data	$D_x = (N_x - X_0)/X_1$	$D_x = 10^{(N_x - X_0)/X_1}$
Device to data	$D_x = (R_x/V_x - X_0)/X_1$	$D_x = 10^{(R_x/V_x - X_0)/X_1}$
Device to normal	$N_x = R_x/V_x$	$N_x = R_x/V_x$

Table D-27: Equations for X-axis Coordinate Conversion

The y - and z -axis coordinates are converted in exactly the same manner, with the exception that there is no z device coordinate and that logarithmic z -axes are not permitted.

!C

The cursor system variable. Currently, the only function of this system variable is to contain the subscript of the largest or smallest element found by the MAX and MIN functions. That information is better obtained through the optional output arguments to those routines. !C is included only for compatibility with old versions of IDL.

!D

This system variable is a structure that contains information about the current graphics output device (or window, on a windowing system). Fields, in alphabetical order, are:

FILL_DIST

The line interval, in device coordinates, required to obtain a solid fill.

FLAGS

A longword of flags that provide information about the current device. Each bit is a flag encoded as shown in the following table.

Bit	Value	Function
0	1	Device has scalable pixel size (e.g., PostScript).
1	2	Device can output text at an arbitrary angle using hardware.
2	4	Device can control line thickness with hardware.
3	8	Device can display images.
4	16	Device supports color.
5	32	Device supports polygon filling with hardware.
6	64	Device hardware characters are monospace.
7	128	Device can read pixels (i.e., it supports TVRD).
8	256	Device supports windows.
9	512	Device prints black on a white background (e.g., printers are plotters).
10	1024	Device has <i>no</i> hardware characters.
11	2048	Device does line-fill style polygon filling in hardware.
12	4096	Device will apply Hershey-style embedded formatting commands to device fonts.
13	8192	Device is a pen plotter.
14	16384	Device can transfer 16-bit pixels.
15	32768	Device supports Kanji characters.
16	65536	Device supports widgets.
17	131072	Device has Z-buffer.
18	262144	Device supports TrueType fonts.

Table D-28: !D.FLAGS Bit Definitions

To test whether a particular bit is set on your system, use an IDL command like the following:

```
IF (!D.FLAGS AND value) NE 0 THEN PRINT, 'Bit is set.'
```

where *value* is the value associated with the bit you wish to examine. For example, to check whether the device supports color, use:

```
IF (!D.FLAGS AND 16) NE 0 THEN PRINT, 'Bit is set.'
```

N_COLORS

The number of allowed color values. In the case of devices with windows, this field is set after the window system is initialized. For a monochrome system, !D.N_COLORS is 2. For TrueColor displays, !D.N_COLORS is 2^{24} (roughly 16.7 million colors).

The low 8 bits, bits 0 to 7, of the color index are written to the red channel; bits 8 to 15 are written to the green; and bits 16 to 23 are written to the blue. For example, a given RGB, the index is $R + 256(G + 256B)$. To create a plot with a given color (assuming linear lookup tables), use the following statement:

```
PLOT, X, Y, COLOR = R + 256L * (G + 256L * B)
```

NAME

A string containing the name of the device.

ORIGIN

A two-element integer array containing the current pan/scroll offset. An offset of (0, 0) is normal. Positive offsets shift the display memory to the right and upwards. This field has relevance only with devices with hardware pan and scroll abilities.

TABLE_SIZE

The number of color table indices.

Note

For TrueColor visuals, !D.TABLE_SIZE will always be 256. If the visual depth is less than 24 bits, IDL emulates 256 entries.

UNIT

The logical number of the file open for output by the current graphics device. This field only has meaning for devices that write to a file if the file is accessible to the user from IDL, and is 0 if no file is open.

For example, the PostScript driver fills this field with the unit number of the file open for PostScript output. In the case of Tektronix output to a file, !D.UNIT may be set to either + or – the logical unit number. In the case of the Metafile device (Windows Metafile Format) output, !D.UNIT is always 0, because the file is not accessible to the user from IDL.

WINDOW

The index of the currently open window. This field is set to -1 if no window is currently open. This field is used only with devices that support windows.

X_CH_SIZE

Y_CH_SIZE

The width and height of the rectangle that encloses the “average” character in the current font, in device units (usually pixels).

These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.)

The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width is the value of X_CH_SIZE. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines is determined explicitly by the value of Y_CH_SIZE.

For device fonts, the character size is fixed. When the device font system is in use, the value of X_CH_SIZE is silently ignored, and only the Y_CH_SIZE value is used.

X_PX_CM

Y_PX_CM

The approximate number of pixels per centimeter in the X and Y directions.

X_SIZE

Y_SIZE

The total size of the display or window in the X and Y directions, in device units.

X_VSIZE

Y_VSIZE

The size of the visible area of the display or window. This area can be smaller than the total size fields.

ZOOM

This field contains the current X and Y zoom factors for the display or window. This field has relevance only with devices equipped with hardware zoom. A zoom factor of [1, 1] is normal.

!ORDER

Controls the direction of image transfers when using the TV, TVSCL, and TVRD procedures. If !ORDER is 0, images are transferred from bottom to top, i.e. the row with a 0 subscript is written on the bottom. Setting !ORDER to 1, transfers images from top to bottom.

!P

The main plotting system variable structure. All fields, except !P.MULTI, have a directly corresponding keyword parameter in the plot procedures: PLOT, OPLOT, CONTOUR, and SURFACE. Fields, in alphabetical order, are:

BACKGROUND

The background color index or 24-bit color value. When erasing the screen or page, all pixels are set to this color. The default value is 0. Not all devices support this feature.

Warning

If !P.NOERASE (or the NOERASE keyword) is set, the value of !P.BACKGROUND (or the BACKGROUND keyword) is ignored.

CHANNEL

The default source or destination channel. This field has meaning only on graphics devices that contain multiple display channels, and is device dependent. It may contain either a channel mask or index.

CHARSIZE

The overall character size of all annotations when Hershey fonts are selected. This field has no effect on the character size when hardware (device) fonts are selected, except for devices that support scalable pixel sizes (i.e., Postscript). Note, however, that !P.CHARSIZE always affects the layout and scaling of a plot, regardless of the font system being used. The default size is 1.0.

CHARTHICK

An integer specifying the thickness of the lines used to draw the characters when using the vector drawn fonts. This field has no effect on the appearance of characters drawn with the hardware fonts. Normal thickness is 1.

CLIP

The device coordinates of the clipping window, a 6-element vector of the form $[x_0, y_0, x_1, y_1, z_0, z_1]$, specifying two opposite corners of the volume to be displayed. In the case of two-dimensional displays, the Z coordinates can be omitted. Normally, the clipping window coordinates are implicitly set by PLOT, CONTOUR, SHADE_SURF, and SURFACE to correspond to the plot window. You may also manually set !P.CLIP if you want to specify a different rectangular clipping window or if the clipping coordinates have not yet been set in the current IDL session.

COLOR

The default color index or 24-bit color value. Color index values are specified with a single integer between 0 and 255. 24-bit color values are specified using a hexadecimal value specifying the blue, green, and red values in a string with the following format:

```
'bbgrr'x
```

where *bb* is a hexadecimal number specifying the blue value, *gg* is a hexadecimal number specifying the green value, and *rr* is a hexadecimal number specifying the red value.

To set the color used for all subsequent plots to color index 160, use the following statement:

```
!P.COLOR = 160
```

To specify that all subsequent plots should be drawn in pure blue on a system that uses 24-bit color, use the following statement:

```
!P.COLOR = 'FF0000'x
```

Most plotting routines also accept a `COLOR` keyword that overrides the value of `!P.COLOR` for the current routine. To set the color of a plot to color-index 120, regardless of the value of `!P.COLOR`, use the following statement:

```
PLOT, INDGEN(30), COLOR = 120
```

By default, `!P.COLOR` is set to the number of available colors minus one. See [“N_COLORS”](#) on page 5667 for more information on defining a color.

The interpretation of the color index varies among the devices supported by IDL. With indexed color video displays, this index selects a color (normally a red, green, blue (RGB) triple stored in a device table). You can control the color selected by each color index with the `TVLCT` procedure which loads the device color tables.

Other devices have a fixed color associated with each color index. With plotters, for example, the correspondence between colors and color index is established by the order of the pens in the carousel.

FONT

An integer that specifies the graphics text font system to use. Set `FONT` equal to -1 to select the Hershey character fonts, which are drawn using vectors. Set `FONT` equal to 0 (zero) to select the device font of the output device. Set `FONT` equal to 1 (one) to select the TrueType font system. See [Appendix H, “Fonts”](#), for a complete description of IDL’s font systems.

LINestyle

The default style of the lines used to connect points. A line style index of 0 yields a solid line. See [“LINestyle”](#) on page 5621 for a description of the linestyles.

MULTI

`!P.MULTI` allows making multiple plots on a page or screen. It is a 5-element integer array defined as follows:

`!P.MULTI[0]` contains the number of plots remaining on the page. If `!P.MULTI[0]` is less than or equal to 0, the page is cleared, the next plot is placed in the upper left hand corner, and `!P.MULTI[0]` is reset to the number of plots per page.

Setting `!P.MULTI[0]` to a value greater than zero can be used to manually set the plotting area to a specific row and column. For example, to plot in the lower left corner of a window of two rows and two columns, set `!P.MULTI` as follows:

```
!P.MULTI=[2,2,2]  
PLOT, X, Y
```

!P.MULTI[1] is the number of plot columns per page. If this value is less than or equal to 0, one is assumed. If more than two plots are ganged in either the X or Y direction, the character size is halved.

!P.MULTI[2] is the number of rows of plots per page. If this value is less than or equal to 0, one is assumed.

!P.MULTI[3] contains the number of plots stacked in the Z dimension.

!P.MULTI[4] is 0 to make plots from left to right (column major), and top to bottom, and is 1 to make plots from top to bottom, left to right (row major).

Note

If !P.MULTI[0] is zero, an erase will occur before the current plot is displayed (unless the /NOERASE keyword is set). This is true no matter whether !P.POSITION and/or !P.REGION are set.

For example, to gang two plots across the page:

```
!P.MULTI = [0, 2, 0, 0, 0]
PLOT, X0, Y0           ;Make left plot.
PLOT, X1, Y1           ;Right plot.
```

To gang two plots vertically:

```
!P.MULTI = [0, 0, 2, 0, 0]
PLOT, X0, Y0           ;Make top plot.
PLOT, X1, Y1           ;Bottom plot.
```

To make four plots per page, two across and two up and down:

```
!P.MULTI = [0, 2, 2, 0, 0]
```

and then call plot four times.

To reset !P.MULTI back to the normal one plot per page:

```
!P.MULTI = 0
```

See [“Multiple Plots on a Page”](#) on page 1907 for additional examples. See [“Specifying the Location of the Plot”](#) on page 1909 for information on how !P.MULTI relates to plot location.

NOCLIP

A field which, if set, inhibits the clipping of the graphic vectors and vector-drawn text. By default, most routines clip to the plotting window, with the exception of PLOTS and XYOUTS. !P.CLIP contains the clipping rectangle.

NOERASE

Set this field to a non-zero value to inhibit erasing the screen before plotting.

Warning

If !P.NOERASE (or the NOERASE keyword) is set, the value of !P.BACKGROUND (or the BACKGROUND keyword) is ignored.

NSUM

The number of adjacent points to average to obtain a plotted point.

POSITION

Specifies the normalized coordinates of the rectangular plot window. This is a four element floating point vector (x_0, y_0, x_1, y_1) containing the normalized coordinates of the plot-data window, where (x_0, y_0) is the origin, and (x_1, y_1) is the upper right corner.

!P.POSITION determines the plotting window. This variable is ignored if x_0 equals x_1 (that is, if !P.POSITION[0] EQ !P.POSITION[2], which is the default), or if the POSITION keyword is present. If set, it overrides the effect of the MARGIN and !P.MULTI variables and keywords.

Note

If !P.POSITION (or the POSITION keyword) or !P.REGION is set, all but the first element of !P.MULTI are ignored.

See “[Specifying the Location of the Plot](#)” on page 1909 for more information.

PSYM

The default plotting symbol index. Each point drawn by PLOT, PLOTS, and OPLOT is marked with a symbol if this field is non-zero. If this field is set equal to a positive value less than 10, no lines are drawn connecting the data points. See “[PSYM](#)” on page 5623 for a list of symbols and the behavior of positive and negative values.

REGION

A four element vector that specifies the normalized coordinates of the rectangle enclosing the plot region, which includes the plot data window and its surrounding annotation area. It is in the same form as !P.POSITION, (x_0, y_0, x_1, y_1) , where (x_0, y_0) is the origin, and (x_1, y_1) is the upper right corner. It is ignored if !P.REGION[0] is equal to !P.REGION[2].

Note

!P.POSITION (or the POSITION keyword) takes precedence over !P.REGION.

See [“Specifying the Location of the Plot”](#) on page 1909 for more information.

SUBTITLE

The plot subtitle, placed under the X axis label.

T

Contains the homogeneous 4 x 4 transformation matrix. This field is a two-dimensional array of double-precision floating-point values. For more information about transformations, refer to [“Coordinates of 3-D Graphics”](#) (Chapter 5, *Using IDL*).

T3D

Enables the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix.

THICK

The thickness of the lines connecting points. 1.0 is normal.

TITLE

The main plot title.

TICKLEN

The length of the tick marks, expressed as a fraction of the plot size (from 0.0 to 1.0). The default is 0.02. A value of 0.5 makes a grid. Negative values make the tick marks point outward.

!X, !Y, !Z

The system variables !X, !Y, and !Z, are structures of type AXIS, that affect the appearance and scaling of the three axes. The fields for !X, !Y, and !Z have identical fields with identical meanings and usage. In addition, almost all fields have corresponding keyword parameters, with identical function, but with temporary effect. For example, to suppress the minor tick marks on the X axis using the !X system variable, you could use the command:

```
!X.MINOR = -1
```

To suppress the tick marks for just one call to plot, you could use the command:

```
PLOT, X, Y, XMINOR = -1
```

The name of the keyword parameter is simply the name of the system variable field, prefixed with the letter X, Y, or Z.

The fields for these system variables, in alphabetical order are:

CHARSIZE

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This field has no meaning when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor. For example, setting !P.CHAR.SIZE to 2.0, and !X.CHAR.SIZE to 0.5 results in a character size of 1.0 for the X axis.

CRANGE

The output axis range. Setting this variable has no effect; set ![XYZ].RANGE to change the range. ![XYZ].CRANGE[0]) always contains the minimum axis value, and ![XYZ].CRANGE[1] contains the maximum axis value of the last plot before extending the axes.

Note

If the axis is logarithmic, the CRANGE field reports the log (base 10) of the minimum and maximum axis values.

Example 1:

```
;Create a 10-element array.
a = INDGEN(10)

;Plot the straight line.
PLOT, a

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

IDL prints:

```
0.00000      10.0000
```

Example 2:

```
;Plot a with logarithmic scaling on the X axis.
PLOT, a, /XLOG
```

```

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE

```

The axis is scaled from 10^{-12} to 10^2 . IDL prints:

```

-12.0000      2.00000

```

GRIDSTYLE

The index of the linestyle to be used for tick marks and grids. See [“LINESTYLE”](#) on page 5621 for a description of the linestyles

MARGIN

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. The plot window is the rectangular area that contains the plot data, i.e. the area enclosed by the axes.

The default values for `!X.MARGIN` are [10, 3] yielding a 10-character wide left margin and a 3-character wide right margin. The values for `!Y.MARGIN` are [4, 2], for a 4-character high bottom margin and a 2-character high top margin. While specifying `!Z.MARGIN` will not cause an error, Z margins are currently ignored.

When calculating the size and position of the plot window, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting `!P.POSITION`, or specification of the `POSITION` parameter overrides the effect of this field. See [“Specifying the Location of the Plot”](#) on page 1909 for more information.

MINOR

The number of minor tick mark intervals. If `!X.MINOR` is 0, the default, the number of minor tick intervals is automatically determined from the tick mark increment.

You can force a given number of minor tick intervals by setting this field to the desired number. To suppress minor tick marks, set `!X.MINOR` to -1.

OMARGIN

A 2-element array specifying the “outer” margin on the left (bottom) and right (top) sides of a multi-plot window, in units of character size. A multi-plot window is created by setting the `!P.MULTI` system variable field. `OMARGIN` controls the amount of space around the entire plot area, including individual plot margins set with `!X.MARGIN` and `!Y.MARGIN`. The default values for `!X.OMARGIN` and `!Y.OMARGIN` are [0, 0].

When calculating the size and position of the individual plots, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

RANGE

The input axis range, a 2-element vector. The first element is the axis minimum, and the second is the maximum. Set this field, or use the corresponding keyword parameter, to specify the data range to plot. If axis end point rounding is selected (see STYLE above), the final axis range may not be equal to this input range. The field !X.CRANGE contains the axis range used for the plot before extending the axes. Set both elements equal to 0 for automatic axis ranges:

```
!X.RANGE = 0
```

For example, to force the X axis to run from 5.5 to 8.3:

```
!X.RANGE = [5.5, 8.3]
PLOT, X, Y
```

Alternatively, by using keywords:

```
PLOT, X, Y, XRANGE=[5.5, 8.3]
```

Note that even though the range was set to (5.5, 8.3), the resulting plot has a range of (5.5, 8.5), because axis rounding is the default.

REGION

Contains the normalized coordinates of the region. This field is similar to WINDOW, in that it is set by the graphics procedures and is a 2-element floating point array. To change the default plotting region, set !P.REGION.

S

The scaling factors for converting between data coordinates and normalized coordinates (a 2-element array). The formula for conversion from data (X_d) to normalized (X_n) coordinates is $X_n = S_I X_d + S_0$

If logarithmic scaling is in effect, substitute $\log_{10}(X_d)$ for X_d .

The CONVERT_COORD function can be used to convert between coordinate systems. The user should save and restore these fields when switching between windows or devices with different sizes and/or scaling.

STYLE

The style of the axis encoded as bits in a longword. The axis style can be set to exact, extended, none, or no box using this field. The following table lists the axis style bit values:

Bit	Value	Function
0	1	Exact. By default, the end points of the axis are rounded in order to obtain even tick increments. Setting this bit inhibits rounding, making the axis fit the data range exactly.
1	2	Extend. If this bit is set, the axes are extended by 5% in each direction, leaving a border around the data.
2	4	None. If this bit is set, the axis and its annotation are not drawn.
3	8	No box. Normally, PLOT and CONTOUR draw a box-style axis with the data window surrounded by axes.
4	16	Inhibits setting the Y axis minimum value to zero when the data are all greater than 0. The keyword YNOZERO sets this bit temporarily.

Table D-29: Axis Style Bit Values

Note that this system variable field is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the !X.STYLE system variable to 1+8, or 9.

For example, to set the Y axis style to exact using the !Y system variable:

```
!Y.STYLE = 1
```

or by using a keyword parameter:

```
PLOT, X, Y, YSTYLE = 1
```

THICK

The thickness of the axis line. 1.0 is normal.

TICKFORMAT

Set this field to a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels.

See “[XYZ]TICKFORMAT” on page 5630 for more information.

TICKINTERVAL

A scalar indicating the interval between major tick marks for the first axis level. This setting takes precedence over ![XYZ].TICKS.

For example, if !X.TICKUNITS=[“Seconds”, “Hours”, “Days”], and !X.TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

See “[XYZ]TICKINTERVAL” on page 5632 for more information.

TICKLAYOUT

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

See “[XYZ]TICKLAYOUT” on page 5633 for more information.

TICKLEN

The lengths of tick marks (expressed in normal coordinates) for the individual axes.

TICKNAME

The annotation for each tick. A string array of up to 60 elements. Setting elements of this array allows direct specification of the tick label. If this element contains a null string, the default value, IDL annotates the tick with its numeric value. Setting the element to a 1-blank string suppresses the tick annotation.

For example, to produce a plot with an abscissa labeled with the days of the week:

```
;Set up X axis tick labels.
!X.TICKNAME = ['SUN', 'MON', 'TUE', 'WED', $
              'THU', 'FRI', 'SAT']

;Use six tick intervals, requiring seven tick labels.
!X.TICKS = 6

;Plot the data, this assumes that Y contains 7 elements.
PLOT, Y
```

The same plot can be produced, using keyword parameters, with:

```
;Set fields, as above, only temporarily.
PLOT, Y, XTICKN = ['SUN', 'MON', 'TUE', 'WED', $
                 'THU', 'FRI', 'SAT'], XTICKS = 6
```

TICKS

The number of major tick intervals to draw for the axis. If `!X.TICKS` is set to 0, the default, IDL will select from three to six tick intervals. Setting this field to n , where $n > 1$, produces exactly n tick intervals, and $n+1$ tick marks. Setting this field equal to 1 suppresses tick marks.

TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling.

Note

The singular form of each of the time value strings is also acceptable (e.g, `!X.TICKUNITS='Day'` is equivalent to `!X.TICKUNITS='Days'`).

Note

To set the `![XYZ].TICKUNITS` field to a single string, the following approach is recommended:

```
!X.TICKUNITS = '' ; Clear all previous tick unit
strings.
!X.TICKUNITS = ['Days'] ;Single unit string in array.
```

The following:

```
!X.TICKUNITS = 'Days'
```

will copy the 'Days' string to all levels, resulting in a multi-level axis.

See “[XYZ]TICKUNITS” on page 5634 for more information.

TICKV

An array of up to 60 elements containing the data values for each tick mark. You can directly specify the location of each tick by setting `!X.TICKS` to the number of tick marks (the number of intervals plus 1) and storing the data values of the tick marks in

`!X.TICKV`. If, as is true by default, `!X.TICKV[0]` is equal to `!X.TICKV[1]`, IDL automatically determines the value of the tick marks.

TITLE

A string containing the axis title.

TYPE

The type of axis, 0 for linear, 1 for logarithmic.

WINDOW

Contains the normalized coordinates of the axis end points, the plot data window. This field is set by `PLOT`, `CONTOUR`, `SHADE_SURF`, and `SURFACE`. Changing its value has no effect. A 2-element floating point array. To change the default plotting window, set `!P.POSITION`. The keyword parameter `POSITION` sets the plot data window on a per call basis.

Appendix E

IDL System Preferences

The following topics are included in this appendix:

About IDL System Preferences	5684	Windows Graphics Preferences	5705
General User Environment Preferences ..	5693	X Window System Graphics Preferences	5708
Directory and Search Path Preferences ..	5697	Windows Runtime Preferences	5712
!CPU Settings Preferences	5702	Support for Obsolete Preference Mechanisms .	5714
General Graphics Preferences	5704		

About IDL System Preferences

System Preferences are internal values that control various aspects of the environment that IDL presents to its users. Preferences supply initial values for many system variables and control the layout of the IDL Workbench and a variety of other aspects of IDL's behavior. Preferences can be specified from a variety of sources. They persist between IDL sessions, meaning that once you get them set in a way that satisfies your needs, you can forget them, and IDL will behave in the way you have specified every time you run it.

Preferences are built into the IDL system and are fixed in number and purpose. Each preference has a name that starts with `IDL_`, and these names are case insensitive.

Note

Preferences that apply only to the IDL Workbench interface are stored separately. You can modify both workbench preferences and many (but not all) IDL system preferences via the IDL Workbench **IDL Preferences** dialog, but only system preferences are described here and only system preferences can be modified using the `IDL_PREF_*` routines.

IDL system preferences have two data types: string and integer (numeric). The numeric preferences are further specialized:

- A numeric preference can have a minimum and/or maximum value beyond which it is not allowed to be set.
- A numeric preference can be discrete, meaning that the possible values are constrained to be one of a fixed set of values. In most cases, IDL lets you reference these values using case-insensitive mnemonic names called *aliases* that make them easier to use and remember. For example, many of IDL's preferences are of an integer type called `BOOLEAN`. Boolean preferences are discrete, with possible values of 1 and 0. The aliases "True", "Yes", and "On" are accepted for the value 1, and "False", "No", and "Off" for 0.

The complete set of IDL system preferences are documented later in this appendix, starting with "[General User Environment Preferences](#)" on page 5693. You can view your current preferences from within IDL by using the following command:

```
HELP, /PREFERENCES
```

The default display shows the preference names, their values, and the source of those values. For a detailed complete view of their state, add the `FULL` keyword to the `HELP` command. See the `PREFERENCES` keyword for more information on its output.

This section of the appendix contains the following information:

- [“Understanding System Preference Sources”](#) on page 5685
- [“Changing Preference Values”](#) on page 5688
- [“Understanding Preference Files”](#) on page 5691
- [“Using Preference Etiquette”](#) on page 5692

Understanding System Preference Sources

The value of each system preference can come from a variety of sources. There is a hierarchy to these sources, and IDL will use the value from the source with the highest priority. This value is called the effective value, to reflect the fact that there might be several sources for a given preference, but only one of them is actually used.

A given IDL system preference can come from one of the following sources. These sources are listed in order of priority; the ones at the top will be used in preference to the ones below. The rest of this section describes the sources, listed here in descending order of priority:

- [“Command Line”](#) on page 5685
- [“Environment Variable”](#) on page 5686
- [“IDL Distribution Preference File”](#) on page 5687
- [“User Preference File”](#) on page 5688
- [“IDL Default Value”](#) on page 5688

Command Line

You can specify system preference values from the IDL command line. There are two possible forms of this feature. The first form is specifying the preference name and value directly on the command line. For example, the following starts IDL while setting the default graphics device to PostScript:

```
% idl -IDL_DEVICE ps
```

The second form is using the `-pref` command-line option to specify an IDL preference file that IDL reads when it starts. For information on the syntax of this file, see [“Understanding Preference Files”](#) on page 5691. For example, suppose you had a file named `thr.pref` containing the following lines, which set parameters used by the IDL thread pool:

```
IDL_CPU_TPOOL_MAX_ELTS : 1000000  
IDL_CPU_TPOOL_MIN_ELTS : 500000
```

```
IDL_CPU_TPOOL_NTHREADS : 4
```

Starting IDL with the following command causes these three preferences from `thr.pref` to take effect:

```
% idl -pref=thr.pref
```

Preferences specified directly on the command line take precedence over those specified within a command-line preference file. The direct form is mainly useful for ad-hoc interactive use of IDL, while the preference file form is of particular interest to those writing stand-alone applications in IDL, especially when using the runtime or virtual machine modes of operation. The use of a command line preference file lets authors of such applications control the values of preferences important to the application in a way that is user-adjustable and not hardwired into the application's code.

Preferences set at the command line are not written to the current user's preferences file, and can be modified using the [PREF_SET](#) procedure or the IDL Workbench preferences dialog.

Environment Variable

Environment variables are an operating-system mechanism by which a table of names and associated values are passed between related processes. A parent process passes a copy of its environment to each child process that it creates. Under UNIX, environment variables are usually set in the user's shell-initialization files (`.cshrc`, `.login`, `.profile`, `.bashrc`, etc.). Under Microsoft Windows, the system environment variable dialog is commonly used for this purpose.

Any IDL system preference can have its value defined by an environment variable of the same name. For example, to set the value of the [IDL_PATH](#) preference, which supplies the initial value for the [!PATH](#) system variable, you would define an environment variable named `IDL_PATH`.

Note

Although IDL's preference names are internally case-insensitive, the UNIX environment is case-sensitive. Therefore, you must specify the environment-variable name in uppercase for IDL under UNIX to recognize it. In contrast, the Microsoft Windows environment is case-insensitive, and IDL recognizes any case. A simple rule that will always work is to always use uppercase environment-variable names.

To define an environment variable under Microsoft Windows, use the Environment Variables dialog available through the Windows control panel. Open the dialog by

selecting **Start** → **Settings** → **Control Panel** → **System** → **Advanced** → **Environment Variables**.

To define an environment variable under UNIX, enter the following command (given here in `ks`h/`bash` format; adjust the command as necessary for your shell):

```
export IDL_GR_X_RENDERER=1
```

A preference specified by an environment variable is recognized by any version of IDL running on your system. For this reason, it is often desirable to avoid their use in favor of using a preference file.

A preference whose source is an environment variable can be modified during the current IDL session, using either the [PREF_SET](#) procedure or the IDL Workbench preferences dialog. Changes made using either of these methods will be written to the current user's preferences file, but as long as the environment variable persists it will be the initial source of the preference value each time IDL starts. To alter or remove the environment variable, you must modify it at the source (UNIX shell-configuration file or Windows system dialog).

IDL Distribution Preference File

Every IDL distribution contains an `idl.pref` file within the `pref` subdirectory of the resource directory (`<IDL_DIR>/resource/pref/idl.pref`). The file's syntax is the same as that of the user preference file; for more information, see [“Understanding Preference Files”](#) on page 5691. The file serves as a single place where system administrators can establish global defaults for all of their IDL users, without having to edit the preference file for each of those users separately.

For example, IDL uses a thread pool on systems with multiple CPUs in order to carry out numerical operations more quickly. The default is to use the same number of threads as the system has CPUs, in order to use the hardware to best advantage. This default is usually correct for single-user systems, but can be inconvenient at locations where large multi-CPU systems are being shared simultaneously by scientists using IDL for unrelated work. In such a case, the unrelated IDLs battle each other for CPU access and slow down overall system throughput. The system administrator can establish a more productive default by putting a line such as the following in the distribution preference file:

```
IDL_CPU_TPOOL_NTHREADS : 1
```

A preference whose source is the distribution preference file can be modified during the current IDL session, using either the [PREF_SET](#) procedure or the IDL Workbench preferences dialog. Changes made using either of these methods will be written to the current user's preferences file, but as long as the distribution preference

file contains a value for the preference it will be the initial source of the preference value each time IDL starts.

User Preference File

IDL user preferences are kept in a file named `idl.pref`. The [APP_USER_DIR](#) function is used to determine the location of this file. A distinct and separate user preference file is maintained for each combination of IDL version and operating-system family (UNIX or Microsoft Windows). The path to this file is displayed by the following command:

```
HELP, /PREFERENCES
```

Although you can edit this file directly with any text editor, preferably use the IDL-supplied mechanisms for making changes. The IDL Workbench offers a graphical user interface for managing preferences. See [IDL Preferences](#) for more information. You can also use the [PREF_SET](#) and [PREF_COMMIT](#) procedures for lower-level command-line-based access to the same functionality.

For more information, see “[Understanding Preference Files](#)” on page 5691.

IDL Default Value

Every IDL preference has a built-in default value. This is the value that IDL will use for the preference if a value is not set by any of the other sources described above. You can use the following command to see the default values for all preferences:

```
HELP, /PREFERENCES, /FULL
```

For information on the output, see the documentation for the [PREFERENCES](#) and [FULL](#) keywords to [HELP](#).

Changing Preference Values

This section provides information on setting and committing changes to IDL system preferences, including details of the routines used to work with preferences, the pending state of changed preferences, and when committed preference changes take effect.

IDL Workbench Preferences Dialogs

Many, but not all, IDL system preferences can be set by changing values in the IDL Workbench **IDL Preferences** dialog. Changing a value in the **Preferences** dialog and clicking **Apply** is equivalent to setting the preference with the `PREF_SET` routine with the `COMMIT` keyword. System preferences that can be set in the Preferences

dialog are noted in the individual preference descriptions provided in the following topics. See [IDL Preferences](#) for more on the IDL Workbench Preferences dialog.

Preference Routines

There are four routines in IDL that provide user-level access to the preference system:

- **PREF_COMMIT** — used to commit preferences or discard pending values. See “[PREF_COMMIT](#)” on page 1970.
- **PREF_SET** — used to set the value of a user preference by providing a new value or by setting it to its default value. See “[PREF_SET](#)” on page 1980.
- **PREF_GET** — used to obtain detailed information about the status of a preference. See “[PREF_GET](#)” on page 1973.
- **PREF_MIGRATE** — used to import preferences from other versions of IDL into the current version. This routine is written in the IDL language, and uses the other three routines above to do the actual work. See “[PREF_MIGRATE](#)” on page 1978.

Note

Authors of IDL applications should not use these routines in their code to make preference changes. See “[Using Preference Etiquette](#)” on page 5692 for more information.

The Pending State

IDL allows you to change the value of any preference with the [PREF_SET](#) procedure. When you set a new value for a preference, the preference enters a pending state. IDL remembers the change, but continues to use the previously active effective value. In order to make a pending preference value take effect, it must be committed. To commit a preference, IDL takes the following steps:

1. Writes a new user preference file which merges the new changes with the previously specified preference values.
2. Updates its internal state to make the pending values current.
3. Notifies the various parts of IDL that depend on the altered preference so that they can adapt to the change.

There are two ways to commit a preference:

- **PREF_COMMIT** — used to commit preferences already in the pending state (see “[PREF_COMMIT](#)” on page 1970)

- **PREF_SET** — used with the COMMIT keyword to set and commit a specific preference in a single operation (see “[PREF_SET](#)” on page 1980)

The pending state is useful for applications that allow users to manipulate preferences. In such an application, the user is typically allowed to make changes, but those changes can be discarded without taking effect if the user clicks the **Cancel** button. To implement this, an application uses **PREF_SET** to make the user's changes. If the user confirms the changes by clicking **Done**, **PREF_COMMIT** makes them permanent. Otherwise, they can be discarded by use of the **RESET** keyword. The pending state lifts the burden of tracking a user's changes from such applications, and greatly simplifies their implementation.

Note

Pending changes are indicated as such in `HELP , /PREFERENCES` output.

Note

Authors of IDL applications should not use these routines in their code to make preference changes. See “[Using Preference Etiquette](#)” on page 5692 for more information.

When Committed Changes Take Effect

Once a new preference value has been committed, its new value is used by the rest of IDL to determine some particular aspect of its operation. This change can take effect at one of three possible times:

- **Immediately** — in most cases, changes to a preference are reflected in IDL's operation immediately. For example, preferences are used to supply default values for many system variables. Usually, a change to a preference results in the associated system variable changing to the new value as soon as the new preference value is committed.
- **On reset or restart** — a few preferences do not take effect until the next use of the `.reset_session` or `.full_reset_session` executive commands, or until IDL is exited and restarted. One example of this group is the [IDL_DEVICE](#) preference, which specifies the default direct graphics device. Changes to `IDL_DEVICE` do not cause your current graphics device to be immediately reset. If you later use a reset executive command or restart IDL, however, the new default is used.
- **On restart** — a very small number of preferences only take effect in subsequent IDL sessions. The `IDL_DLM_PATH` preference is one such

preference. Changes to [IDL_DLM_PATH](#) are not seen in the current IDL session, but take effect the next time IDL is run.

The output from the following command describes when changes to each preference take effect:

```
HELP, /PREFERENCES, /FULL
```

For information on the output, see the documentation for the [PREFERENCES](#) and [FULL](#) keywords to [HELP](#).

Understanding Preference Files

An IDL system preference file is a simple text file in which each preference is specified on a single line. The line consists of the preference name, followed by a colon (:) character, followed by the preference value. Empty and comment lines are allowed; IDL ignores them.

Note

If you use the API functionality to commit preference changes, IDL overwrites the user preference file accordingly. Doing so removes any comments that you manually added to the file.

Here is a sample preference file:

```
# Sample IDL preference file
# Author: ITT Visual Information Solutions

# No user information in SAVE and JOURNAL files
IDL_DATAFILE_USER_COMMENTS : 0

# Suppress information messages (alias used)
IDL_QUIET : on

# Buffer size = 1000 lines
IDL_RBUF_SIZE : 1000
```

You can give a preference file any name and extension, but you might want to use the `.pref` extension for clarity.

While you can create and edit preference files using any text editor, in general it is better to modify the user preference file using the API functionality (see “[Preference Routines](#)” on page 5689).

Using Preference Etiquette

The IDL's preference system routines [PREF_SET](#) and [PREF_COMMIT](#) provide programmatic control over the values of preferences saved in an individual user's preference file. **In general, as an IDL application author, you should not use these routines in IDL code.** Since preference values set in the user preference file persist between sessions, changes made by your application using these routines will affect your end user's IDL environment even when he or she is running other applications.

Preference files loaded at application startup provide a much more user-friendly mechanism for specifying preference values that apply only to your application. To use this mechanism, create a preference file that contains the preference values you want to have in effect when your application runs, and include the name of the preference file in the command that launches your application via the `-pref` command-line option. (See [“Command Line Options for IDL Startup”](#) (Chapter 1, *Using IDL*) for details.)

General User Environment Preferences

This section describes the preferences for the general user environment.

IDL_DATAFILE_USER_COMMENTS

The `IDL_DATAFILE_USER_COMMENTS` preference specifies whether or not IDL is allowed to put comments that include user and host name into generated data files, such as `SAVE` and `JOURNAL` files. Such comments are usually considered to be helpful in most environments, but can be a problem for those working in secure environments with specific rules governing the information that is allowed to leave a given security level.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Include user information in SAVE files” in [IDL Preferences](#).

IDL_DEVICE

IDL’s direct graphics system always operates on the current graphics device, which you can change with the [SET_PLOT](#) procedure. The `IDL_DEVICE` preference specifies the initial graphics device that starts out as current.

Committed changes take effect at the next `.reset_session` executive command or in future IDL sessions. The default value is the window system supported by IDL for the target platform: “X” for UNIX systems and “WIN” for Microsoft Windows.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_EDIT_INPUT

The `IDL_EDIT_INPUT` preference sets the initial value of the [!EDIT_INPUT](#) system variable, which determines whether or not the tty-based (non-IDE) command-line version of IDL does command-line editing when reading commands. For related

information on the command recall buffer, see “[IDL_RBUF_PERSIST](#)” on page 5696 and “[IDL_RBUF_SIZE](#)” on page 5696.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_EXCEPT

The IDL_EXCEPT preference sets the initial value of the [!EXCEPT](#) system variable, which controls when IDL checks for invalid mathematical computations (exceptions).

Value	Aliases
0	Never, No
1	OnInterpreterHalt, Halt
2	AfterStmt, Stmt

Committed changes take effect immediately. The default value is OnInterpreterHalt (1).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_MORE

The IDL_MORE preference sets the initial value of the [!MORE](#) system variable, which controls whether IDL should paginate help output sent to a TTY device. This preference has no effect on the IDL Workbench Console view.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_MSG_PREFIX

The IDL_MSG_PREFIX preference sets the value of the [!ERROR_STATE.MSG_PREFIX](#) system variable, which determines the prefix string used for error messages.

Committed changes take effect immediately. The default value is '% '.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_PROMPT

The IDL_PROMPT preference sets the value of the [!PROMPT](#) system variable, which contains the text string that IDL uses to prompt for input.

Committed changes take effect immediately. The default value is 'IDL> '.

This preference can be set in the IDL Workbench **Preferences** dialog. See “IDL Prompt” in [IDL Preferences](#).

IDL_QUIET

The IDL_QUIET preference sets the value of the [!QUIET](#) system variable, which controls whether informational messages are printed (value is 0) or suppressed (1).

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_RBUF_PERSIST

The IDL_RBUF_PERSIST preference determines whether the IDL command recall buffer is saved between IDL sessions. For related information on the recall buffer, see “IDL_EDIT_INPUT” on page 5693 and “IDL_RBUF_SIZE” on page 5696.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Save command history between sessions” in [IDL Preferences](#).

IDL_RBUF_SIZE

The IDL_RBUF_SIZE preference sets the size of the IDL command recall buffer. It must be set to a value greater than or equal to 1. For related information on the recall buffer, see “IDL_EDIT_INPUT” on page 5693 and “IDL_RBUF_PERSIST” on page 5696.

Committed changes take effect immediately. The default value is 500.

This preference can be set in the IDL Workbench **Preferences** dialog. See “History size” in [IDL Preferences](#).

Directory and Search Path Preferences

This section describes the preferences for directories and search paths.

IDL_DIR

The IDL_DIR preference provides the value of the **!DIR** system variable, which contains the location of the IDL distribution that contains the currently running IDL program.

You cannot set IDL_DIR by using user or distribution preference files. The only valid sources for its value are the IDL command line, the IDL_DIR environment variable, or IDL's built-in default value (preferred when possible). The reason for this restriction is that the IDL distribution is an intrinsic part of the IDL program; it must be known before IDL starts running and is not something that can be changed afterwards.

The default value under UNIX is `'/usr/local/itt/idl_xx'`, where `xx` represents the IDL version. The default value under Microsoft Windows is the location where the IDL installer wrote the IDL files on your system (typically `C:\ITT\IDLxx`, where `xx` represents the IDL version).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_DLM_PATH

The IDL_DLM_PATH provides the value of the **!DLM_PATH** system variable, which contains the directories from which IDL loads dynamically loadable modules (DLMs).

Committed changes take effect in future IDL sessions. The default value is `'<IDL_DEFAULT>'`, a special token which IDL replaces at startup with the correct set of directories from the IDL distribution for the currently running version of IDL. If you add directories to IDL_DLM_PATH, you should be careful to retain `<IDL_DEFAULT>` in your new value, or IDL will fail to find the provided DLM files. For example, you can use one of the following commands to add your own DLM directory. Under Windows:

```
PREF_SET, 'IDL_DLM_PATH', 'C:\your\path\here;<IDL_DEFAULT>', $  
/COMMIT
```

Under UNIX:

```
PREF_SET, 'IDL_DLM_PATH', '/your/path/here:<IDL_DEFAULT>', $  
/COMMIT
```

See “[EXPAND_PATH](#)” on page 750 for more information on special syntax and `<IDL_>` tokens you can use in the path definition string. DLM files are IDL- and platform-specific. If you use DLMs with multiple versions of IDL, you might find the `<IDL_BIN_DIRNAME>` token of particular interest when setting up your DLM directories.

By default, the value of `IDL_DLM_PATH` for a given IDL installation will consist of:

- The path to the platform-specific `bin` directory for the current platform
- The path to the `idlde/plugins` subdirectory of the IDL installation

This preference can be set in the IDL Workbench **Preferences** dialog. See “Select Path” in [Paths](#).

IDL_HELP_PATH

The `IDL_HELP_PATH` preference sets the value of the `!HELP_PATH` system variable, which determines the directories where IDL searches for online help files.

Committed changes take effect immediately. The default value is `'<IDL_DEFAULT>'`, a special token which IDL replaces at startup with the correct set of directories from the IDL distribution for the currently running version of IDL. If you add directories to `IDL_HELP_PATH`, you should be careful to retain `<IDL_DEFAULT>` in your new value, or IDL will fail to find the provided help files. For example, you can use one of the following commands to add your own help directory. Under Windows:

```
PREF_SET, 'IDL_HELP_PATH', 'C:\your\path\here;<IDL_DEFAULT>', $
/COMMIT
```

Under UNIX:

```
PREF_SET, 'IDL_HELP_PATH', '/your/path/here:<IDL_DEFAULT>', $
/COMMIT
```

See “[EXPAND_PATH](#)” on page 750 for more information on special syntax and `<IDL_>` tokens you can use in the path definition string.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Select Path” in [Paths](#).

IDL_MAKE_DLL_COMPILE_DIRECTORY

The `IDL_MAKE_DLL_COMPILE_DIRECTORY` preference sets the initial value of the `!MAKE_DLL.COMPILE_DIRECTORY` system variable, which specifies the location where the `MAKE_DLL` and `CALL_EXTERNAL` (with the `AUTO_GLUE`

keyword set) routines do their work. A null string (") for this preference specifies that IDL should create an appropriate platform-specific directory underneath the `.idl` subdirectory of the user's home directory. This default value is highly recommended because it automatically handles multi-platform issues.

Committed changes take effect at the next `.reset_session` executive command or in future IDL sessions. The default value is a null string (").

This preference can be set in the IDL Workbench **Preferences** dialog. See “C library compile directory” in [IDL Preferences](#).

IDL_PATH

The `IDL_PATH` preference provides the initial value of the `!PATH` system variable, which determines the directories that IDL searches for include files and programs written in the IDL language (`.pro` and `.sav`).

Committed changes take effect immediately. The default value is '`<IDL_DEFAULT>`', a special token which IDL replaces at startup with the correct set of directories from the IDL distribution for the currently running version of IDL. If you add directories to `IDL_PATH`, you should be careful to retain `<IDL_DEFAULT>` in your new value, or IDL will fail to find the provided library files. For example, you can use one of the following commands to add your own library directory. Under Windows:

```
PREF_SET, 'IDL_PATH', 'C:\your\path\here;<IDL_DEFAULT>', $
/COMMIT
```

Under UNIX:

```
PREF_SET, 'IDL_PATH', '/your/path/here:<IDL_DEFAULT>', $
/COMMIT
```

See “[EXPAND_PATH](#)” on page 750 for more information on special syntax and `<IDL_>` tokens you can use in the path definition string.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Select Path” in [Paths](#).

IDL_PATH_CACHE_DISABLE

The `IDL_PATH_CACHE_DISABLE` preference determines whether or not the IDL path cache is enabled when IDL starts. For more information on the path cache, see [“PATH_CACHE”](#) on page 1879.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is False (0), meaning that the cache is enabled.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Enable path cache” in [Paths](#).

IDL_START_DIR

The `IDL_START_DIR` preference specifies the initial IDL working directory to be established when the IDL Workbench starts. If the preference is not set, or is set to a null string (' '), the working directory is set to the user’s home directory as defined by the `$HOME` environment variable. (See [“HOME”](#) (Chapter 1, *Using IDL*) for details on how the home directory is determined on Windows platforms.)

If the preference is set to a dot (' . '), the initial IDL working directory is set to the directory from which IDL was started for Unix systems or to the user’s home directory on Windows platforms.

Note

When running IDL in command-line mode, the initial working directory is the directory from which IDL was started. The `IDL_START_DIR` preference is ignored in this situation.

Committed changes take effect in future IDL sessions. The default value is a null string (' ').

This preference can be set in the IDL Workbench **Preferences** dialog. See “Initial Working Directory” in [IDL Preferences](#).

IDL_STARTUP

The `IDL_STARTUP` preference provides the path of a batch file that is executed automatically each time IDL is started and following a `.reset_session` or `.full_reset_session` executive command. (See “[Startup File](#)” (Chapter 1, *Using IDL*) for more information on startup files.) A null string (“”) indicates that there is no startup file.

Note

Startup files are only executed when running an application with a command line. See “[Understanding When Startup Files are Not Executed](#)” (Chapter 1, *Using IDL*) for details.

Committed changes take effect at the next `.reset_session` executive command or in future IDL sessions. The default value is a null string (“”).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Startup file” in [IDL Preferences](#).

IDL_TMPDIR

The `IDL_TMPDIR` preference provides the location of a directory to be used for creating temporary scratch files, as returned by the [GETENV](#) function, if its value is non-null. If the value is a null string, `GETENV` instead returns the path of the standard directory used for this purpose by the current operating system.

Committed changes take effect immediately. The default value is a null string (“”).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Temporary Directory” in [IDL Preferences](#).

!CPU Settings Preferences

The preferences with names starting with the `IDL_CPU_` prefix supply default values for the related fields of the `!CPU` system variable.

IDL_CPU_TPOOL_MAXELTS

The `IDL_CPU_TPOOL_MAXELTS` preference sets the default value of the `!CPU.TPOOL_MAXELTS` system variable, which sets the maximum number of elements in a computation for which IDL uses the thread pool.

Committed changes take effect immediately. The default value is 0, meaning that no maximum limit is imposed, and any computation with at least `!CPU.TPOOL_MINELTS` is a candidate for the thread pool.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_CPU_TPOOL_MINELTS

The `IDL_CPU_TPOOL_MINELTS` preference provides the value of the `!CPU.TPOOL_MINELTS` system variable, which sets the number of elements in a computation that are necessary before IDL uses the thread pool to perform the work.

Committed changes take effect immediately. The default value is 100000.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_CPU_TPOOL_NTHREADS

The `IDL_CPU_TPOOL_NTHREADS` preference specifies the initial value of the `!CPU.TPOOL_NTHREADS` system variable, which sets the number of threads that IDL uses in thread-pool computations.

Committed changes take effect immediately. The default value is 0, which causes IDL to use a thread for every CPU contained in the system on which IDL is currently running.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_CPU_VECTOR_ENABLE

The `IDL_CPU_VECTOR_ENABLE` preference provides the initial value of the `!CPU.VECTOR_ENABLE` system variable if the system supports a vector unit

(!CPU.HW_VECTOR is True). It is ignored if the system lacks a vector unit
(!CPU.HW_VECTOR is False).

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

General Graphics Preferences

Preferences in this category are supported by all versions of IDL.

IDL_GR_TILECACHESIZE

The `IDL_GR_TILECACHESIZE` preference controls how much memory (in megabytes) IDL can use for caching image tiles. IDL allocates memory for caching a tile each time `IDLgrImage::SetTileData` is called. When the amount of allocated memory reaches the value of `IDL_GR_TILECACHESIZE`, the least recently viewed tile or tiles are freed to make room for the new tile. Therefore, the amount of memory used for caching tiles will not grow above this value.

Committed changes take effect immediately. The default value is 256.

If set to 0, there is no limit imposed on the amount of memory used for tiling; memory usage will continue to grow as more tiles are cached. This can result in the operating system paging memory to and from disk when physical RAM is exhausted.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Image tiles” in [Graphics](#).

IDL_GR_TTCACHESIZE

IDL saves TrueType fonts as a set of glyphs; each glyph represents the triangulation data for drawing one character. To minimize the number of times common glyphs must be computed, IDL uses a cache to retain recently computed glyphs in the hope that they can be reused. When IDL finds a needed glyph in the cache, it uses the glyph immediately without rebuilding it. The `IDL_GR_TTCACHESIZE` preference sets the size of the TrueType glyph cache. It must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 256, roughly two TrueType font sets.

This preference can be set in the IDL Workbench **Preferences** dialog. See “TrueType fonts” in [Graphics](#).

Windows Graphics Preferences

Preferences in this section control the default behavior of graphics produced by the Microsoft Windows window system.

IDL_GR_WIN_HEIGHT

The `IDL_GR_WIN_HEIGHT` preference sets the default height of a graphics window created by the Microsoft Windows direct graphics device ('WIN'). It controls the height of a window created by the [WINDOW](#) procedure unless you specify an explicit height to `WINDOW` or the [IDL_GR_WIN_QSCREEN](#) preference is True (1). `IDL_GR_WIN_HEIGHT` must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 512.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Default size” in [Graphics](#).

IDL_GR_WIN_LAYOUT

The `IDL_GR_WIN_LAYOUT` preference specifies the default placement of graphics windows created by the Microsoft Windows direct graphics device ('WIN'). A value of Tile (0) causes windows to be created side-by-side with no overlap. A value of Cascade (1) causes them to be created overlapping.

Value	Alias
0	Tile
1	Cascade

Committed changes take effect immediately. The default value is Tile (0).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Direct graphics layout” in [Graphics](#).

IDL_GR_WIN_QSCREEN

If the `IDL_GR_WIN_QSCREEN` preference is set to True (1), the [IDL_GR_WIN_HEIGHT](#) and [IDL_GR_WIN_WIDTH](#) preferences are ignored.

Instead, the default size of a graphics window created by the Microsoft Windows direct graphics device ('WIN') is one-fourth the size of the screen.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Default size” in [Graphics](#).

IDL_GR_WIN_RENDERER

IDL supports two methods of rendering object graphics: with a hardware graphics accelerator or with a software rendering package. The IDL_GR_WIN_RENDERER preference determines the default method used for volume rendering.

Value	Alias
0	Hardware
1	Software

Committed changes take effect immediately. The default value is Hardware (0).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Rendering method for object graphics” in [Graphics](#).

IDL_GR_WIN_RETAIN

The IDL_GR_WIN_RETAIN preference sets the default method used to provide backing store for windows. When backing store is enabled, a copy of each graphics window is kept in memory; the copy is used to refresh the window when it has been covered and uncovered. IDL's performance might increase when no backing store is used because the amount of memory required to provide backing store can affect the speed at which IDL will run. Settings of this preference correspond to settings of the

RETAIN keyword to the DEVICE procedure. See “[Keywords Accepted by the IDL Devices](#)” on page 5517 for more information

Value	Aliases
0	None
1	Server, System
2	IDLPixmap

Committed changes take effect immediately. The default value is Server (1).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Backing store method for window contents” in [Graphics](#).

IDL_GR_WIN_WIDTH

The IDL_GR_WIN_WIDTH preference sets the default width of a graphics window created by the Microsoft Windows direct graphics device ('WIN'). It controls the width of a window created by the [WINDOW](#) procedure unless you specify an explicit width to WINDOW or the [IDL_GR_WIN_QSCREEN](#) preference is True (1). IDL_GR_WIN_WIDTH must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 640.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Default size” in [Graphics](#).

X Window System Graphics Preferences

The preferences in this section are specific to versions of IDL that support the X Window System. They do not exist in the Microsoft Windows version of IDL.

IDL_GR_X_COLORS

The `IDL_GR_X_COLORS` preference specifies the number of color-table indices to allocate from the shared colormap used by direct graphics. If the value is positive, the specified number of indices are allocated. If the value is negative, all but the specified number are allocated. If the value is 0, all or most of the available color indices are allocated. See the documentation for the `COLORS` keyword to the `WINDOW` procedure for more information on this topic.

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The default value is 0.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_GR_X_DEPTH

The `IDL_GR_X_DEPTH` preference specifies the depth, in bits, of the visual used by IDL.

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The default value is 0, meaning that IDL selects a visual from those available in the server, using the rules described in the documentation for the X Window device.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_GR_X_HEIGHT

The `IDL_GR_X_HEIGHT` preference sets the default height of a graphics window created by the X Window System direct graphics device ('X'). It controls the height of a window created by the `WINDOW` procedure unless you specify an explicit height to `WINDOW` or the `IDL_GR_X_QSCREEN` preference is True (1). `IDL_GR_X_HEIGHT` must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 512.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Default size” in [Graphics](#).

IDL_GR_X_QSCREEN

If the IDL_GR_X_QSCREEN preference is set to True (1), the [IDL_GR_X_HEIGHT](#) and [IDL_GR_X_WIDTH](#) preferences are ignored. Instead, the default size of a graphics window created by the X Window System direct graphics device ('X') is one-fourth the size of the screen.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Default size” in [Graphics](#).

IDL_GR_X_RENDERER

IDL supports two methods of rendering object graphics: with a hardware graphics accelerator or with a software rendering package. The IDL_GR_X_RENDERER preference determines the default method used for volume rendering.

Value	Alias
0	Hardware
1	Software

Committed changes take effect immediately. The default value is Hardware (0).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Rendering method for object graphics” in [Graphics](#).

IDL_GR_X_RETAIN

The IDL_GR_X_RETAIN preference specifies the default type of backing store to use for direct graphics windows. Note that you can override this default using the RETAIN keyword to the [WINDOW](#) or [DEVICE](#) procedures.

Value	Aliases
0	None
1	Server, System
2	IDLPixmap

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The default value is Server (1).

This preference can be set in the IDL Workbench **Preferences** dialog. See “Backing store method for window contents” in [Graphics](#).

IDL_GR_X_VISUAL

The IDL_GR_X_VISUAL preference specifies the preferred X11 visual class for direct graphics windows.

Value	Alias
0	None
1	StaticGray
2	GrayScale
3	StaticColor
4	PseudoColor
5	TrueColor
6	DirectColor

Committed changes take effect immediately if IDL has not yet made a connection to the X Window display. Otherwise, changes take effect in future IDL sessions. The default value is None (0), meaning that IDL selects a visual from those available in

the server, using the rules described in the documentation for the X Windows device (see [“The X Windows Device”](#) on page 5593).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_GR_X_WIDTH

The IDL_GR_X_WIDTH preference sets the default width of a graphics window created by the X Window System direct graphics device ('x'). It controls the width of a window created by the [WINDOW](#) procedure unless you specify an explicit width to WINDOW or the [IDL_GR_X_QSCREEN](#) preference is True (1). IDL_GR_X_WIDTH must be set to a value greater than or equal to 1.

Committed changes take effect immediately. The default value is 640.

This preference can be set in the IDL Workbench **Preferences** dialog. See “Default size” in [Graphics](#).

Windows Runtime Preferences

These preferences exist to support the use of IDL runtime and the IDL Virtual Machine under Microsoft Windows. They are not present in non-Windows versions of IDL.o

Under Microsoft Windows, the `idlrt.exe` program runs runtime or virtual-machine applications. The preferences described here provide default values for parameters to that program if they are not explicitly provided.

If IDL finds an IDL preference file named `idl.pref` in the directory containing the IDL DLL, IDL treats it as a command-line preference file and automatically reads and processes it. This is the most likely way in which the preferences specified in this section are used.

IDL_WINRT_FILE

If you run `idlrt.exe` without specifying an IDL SAVE file, the `IDL_WINRT_FILE` preference supplies the name of the file to use.

Committed changes take effect at the next `idlrt.exe` invocation. The default value is a null string ("").

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_WINRT_FILE_TYPE

If you run `idlrt.exe` without specifying the licensing mode under which it is expected to run, the `IDL_WINRT_FILE_TYPE` preference supplies the mode.

Value	Alias
0	Runtime
1	EmbeddedRuntime
2	VirtualMachine

Committed changes take effect at the next `idlrt.exe` invocation. The default value is Runtime (0).

This preference cannot be set in the IDL Workbench **Preferences** dialog.

IDL_WINRT_ICON

The `IDL_WINRT_ICON` preference specifies the file containing the icon to use with a runtime or virtual-machine application.

Committed changes take effect at the next `idlrt.exe` invocation. The default value is a null string (`""`), indicating that the standard IDL icon should be used.

This preference cannot be set in the IDL Workbench **Preferences** dialog.

Support for Obsolete Preference Mechanisms

Versions of IDL prior to version 6.2 did not have the preference system described in this appendix. Those older versions used different mechanisms to communicate user settings at startup:

- **!EDIT_INPUT and recall buffer size** — the default size of the IDL command recall buffer is 20 lines. To change this, you were allowed to set the value of the `!EDIT_INPUT` system variable to any value larger than 1 within your IDL startup file (as controlled by the `IDL_STARTUP` preference). If IDL found such a value for `!EDIT_INPUT`, it used it to size the recall buffer.
- **X11 Graphics Options** — a number of X11 options can be specified with X11 resources, commonly specified in `.xdefaults` or `.idlde` files.

To provide backwards compatibility with older versions, current versions of IDL are still able to check those sources for user settings and to transfer them, if found, to the corresponding IDL preference setting. The following table shows how IDL maps from one to the other:

Source	IDL Preference
<code>(!EDIT_INPUT gt 1)</code> in IDL startup file	<code>IDL_RBUF_SIZE</code>
<code>idl.retain</code> (X11 resource)	<code>IDL_GR_X_RETAIN</code>
<code>idl.graphicsWindowWidth</code> (X11 resource)	<code>IDL_GR_X_WIDTH</code>
<code>idl.graphicsWindowHeight</code> (X11 resource)	<code>IDL_GR_X_HEIGHT</code>
<code>idl.graphicsWindow14Screen</code> (X11 resource)	<code>IDL_GR_X_QSCREEN</code>
<code>idl.graphicsFontCache</code> (X11 resource)	<code>IDL_GR_TTCACHESIZE</code>
<code>idl.renderer</code> (X11 resource)	<code>IDL_GR_X_RENDERER</code>
<code>idl.gr_visual</code> (X11 resource)	<code>IDL_GR_X_VISUAL</code>
<code>idl.gr_depth</code> (X11 resource)	<code>IDL_GR_X_DEPTH</code>
<code>idl.colors</code> (X11 resource)	<code>IDL_GR_X_COLORS</code>

In all such cases, IDL goes through the following steps:

1. If the `IDL_PREF_OBSOLETE_MIGRATE` preference is set to True (1), the IDL preference system examines the obsolete source. Otherwise, it quietly ignores the source.

2. If all of the following are true, IDL updates the user-preference file so that it contains the value from the obsolete source:
 - An obsolete source provides a value for a preference value
 - The value it provides is different from the IDL default value for that preference
 - The current value of the corresponding IDL preference has the default source (i.e., it has not been set)

In this way, the value migrates from the older mechanism into the IDL preference system. This migration can happen only once because once a preference has migrated, the IDL preference no longer has the default source.

3. If the value was migrated, IDL issues an informational message explaining that it has happened.
4. If a value from an obsolete source exists, but IDL is unable to use it for any of the reasons described in Step 2, and if the `IDL_PREF_OBSOLETE_WARN` preference is set to True (1), IDL issues an informational message explaining that the obsolete value was seen, but not used.

This process is intended as an aid to migration from the older system to the newer one. The default values of both preferences used to control it is True (1), in order to maximize the number of users it can assist. However, if you have successfully moved to newer versions of IDL or find the messages they produce annoying, you can set both preferences to False by using the following commands:

```
PREF_SET, 'IDL_PREF_OBSOLETE_MIGRATE', 'False'
PREF_SET, 'IDL_PREF_OBSOLETE_WARN', 'False'
PREF_COMMIT
```

Alternatively, you can edit IDL startup files, `.xdefault` files, `.idlde` files, and any other X11 resource files to remove the obsolete settings.

IDL_PREF_OBSOLETE_MIGRATE

The `IDL_PREF_OBSOLETE_MIGRATE` preference determines whether the IDL preference system consults older sources of information when determining preference values. See the description above for more information on this preference.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

IDL_PREF_OBSOLETE_WARN

If [IDL_PREF_OBSOLETE_MIGRATE](#) is set to True (1) and an obsolete source provides a value that cannot be used, the `IDL_PREF_OBSOLETE_WARN` preference determines whether or not IDL issues an informational message explaining that this has happened. See the description above for more information on this preference.

Value	Aliases
0	False, No, Off
1	True, Yes, On

Committed changes take effect immediately. The default value is True (1).

Appendix F Special Characters

Within the IDL environment, a number of characters have special meanings.

The following table lists characters with special interpretations and states their functions in IDL. These characters are discussed further in the descriptions following the table.

Character	Function
!	First character of system variable names and font-positioning commands
'	Delimit string constants
'	Indicate part of octal or hex constant
;	Begin comment field

Table F-30: Special Characters

Character	Function
\$	Continue current command on the next line
	Issue operating system command if entered on a line by itself
"	Delimit string constants or precede octal constants
.	Indicate constant is floating point
	Start executive command
&	Separate multiple statements on one line
:	End label identifiers
	Separate start and end subscript ranges
*	Multiplication operator
	Array subscript range
	Pointer dereference (if in front of a valid pointer)
@	Include file
	Execute IDL batch file
?	Invokes online help when entered at the IDL command line
	Part of the ?: ternary operator used in conditional expressions

Table F-30: Special Characters (Continued)

Exclamation Point (!)

The exclamation point is the first character of names of IDL system-defined variables. System variables are predefined scalar variables of a fixed type. Their purpose is to override defaults for system procedures, to return status information, and to control the action of IDL.

Apostrophe (')

The apostrophe delimits string literals and indicates part of an octal or hex constant.

Semicolon (;)

The semicolon is the first character of the optional comment field of an IDL statement. All text on a line following a semicolon is ignored by IDL. A line can consist of a comment only or both a valid statement and a comment.

Dollar Sign (\$)

The dollar sign at the end of a line indicates that the current statement is continued on the following line. The dollar sign character can appear anywhere a space is legal except within a string constant or between a function name and the first open parenthesis. Any number of continuation lines are allowed.

When the \$ character is entered as the first character after the IDL prompt, the rest of the line is sent to the operating system as a command. If \$ is the only character present, an interactive subprocess is started. Under UNIX, IDL execution suspends until the new shell process terminates.

Quotation Mark (")

The quotation mark precedes octal numbers, which are always integers, and delimits string constants. Example: "100B is a byte constant equal to 64 base 10 and "Don't drink the water" is a string constant.

Period (.)

The period or decimal point indicates in a numeric constant that the number is of floating-point or double-precision type. Example: 1.0 is a floating-point number. Also, in response to the IDL prompt, the period begins an executive command. For example,

```
.run myfile
```

causes IDL to compile the file *myfile.pro*. If *myfile.pro* contains a main program, the program also will be executed. In addition, the period precedes the name of a tag when referring to a field within a structure. For example, a reference to a tag called NAME in a structure stored in the variable A is A.NAME.

Ampersand (&)

The ampersand separates multiple statements on one line. Statements can be combined until the maximum line length is reached. For example, the following line contains two statements:

```
I = 1 & PRINT, 'value:', I
```

Colon (:)

The colon ends label identifiers. Labels can only be referenced by GOTO and ON_ERROR statements. The following line contains a statement with the label LOOP1.

```
LOOP1: X = 2.5
```

The colon also separates the starting and ending subscripts in subscript range specifiers. For example, A(3:6) designates elements three to six of the variable A.

Asterisk (*)

The asterisk represents one of the following, depending on context:

1. Multiplication (3 * 3).
2. An ending subscript range equal to the size of the dimension. For example, A[3:*] represents all elements of the vector A from A[3] to the last element, while B[* , 3] represents all elements of row four of matrix B.
3. A pointer dereference operation. For example, if ptr is a valid pointer (created via the PTR_NEW function), then *ptr is the value held by the heap variable that ptr points to. For more information on IDL pointers, see [“Operations on Pointers”](#) (Chapter 17, *Application Programming*).

At Sign (@)

The “at” sign is used both as an include character and to signal batch execution.

@ as an Include Character

The “at” sign at the beginning of a line causes the IDL compiler to substitute the contents of the file whose name appears after the @ for the line. If the full path name is not specified after the @ symbol, IDL searches the current directory and the list of directories specified by the system variable !PATH.

For example, the line

```
@doit
```

when included in a file, causes the file *doit.pro* to be compiled in its place. (The suffix *.pro* is the default for IDL program files.) When the end of the file is reached, compilation resumes at the line after the @.

@ to Signal Batch Processing

When IDL is running in interactive mode, a line beginning with the character @ is entered in response to the IDL prompt and the file is opened for batch input. See [Chapter 3, “Executing Batch Jobs in IDL”](#) (*Application Programming*) for details.

Question Mark (?)

The question mark is used as follows:

- When entered at the IDL command line, the IDL online help facility is invoked.
- Used in conditional expressions as part of the ?: ternary operator. For example:

```
; A shorter way of saying IF (a GT b) THEN z=a ELSE z=b:  
z = (a GT b) ? a : b
```

For more on conditional expressions, see [“Working with Conditional Expressions”](#) (Chapter 12, *Application Programming*).

Appendix G

Reserved Words

Variables, user-written procedures, and user-written functions should not have the same names as IDL functions or procedures. Re-using names of IDL routines can lead to syntax errors or to “hiding” variables. In addition, certain words representing IDL language constructs are strictly forbidden—using any of these *reserved words* as a variable, procedure, or function name will cause an immediate syntax error. The following table lists all of the reserved words in IDL.

AND	BEGIN	BREAK
CASE	COMMON	COMPILE_OPT
CONTINUE	DO	ELSE
END	ENDCASE	ENDELSE
ENDFOR	ENDIF	ENDREP
ENDSWITCH	ENDWHILE	EQ
FOR	FORWARD_FUNCTION	FUNCTION

GE	GOTO	GT
IF	INHERITS	LE
LT	MOD	NE
NOT	OF	ON_IOERROR
OR	PRO	REPEAT
SWITCH	THEN	UNTIL
WHILE	XOR	

Appendix H

Fonts

The following topics are covered in this appendix:

Overview of Fonts in IDL	5726	Controlling Size, Position and Font Use	5743
Choosing a Font Type	5727	Embedded Formatting Commands	5745
Fonts in IDL Direct vs. Object Graphics	5729	Formatting Command Examples	5749
About Hershey Vector Fonts	5730	TrueType Font Samples	5755
About TrueType Fonts	5732	Hershey Vector Font Samples	5760
About Device Fonts	5736		

Overview of Fonts in IDL

IDL uses three font systems for writing characters on the graphics device: Hershey (vector) fonts, TrueType (outline) fonts, and device (hardware) fonts. This chapter describes each of the three types of fonts, discusses when to use each type, and explains how to use fonts when creating graphical output in IDL.

Hershey Vector Fonts

Hershey vector-drawn fonts, also referred to as *Hershey fonts*, are drawn as lines. They are device-independent (within the limits of device resolution) and can be used in Direct Graphic and Object Graphic displays. All Hershey vector fonts included with IDL are guaranteed to be available in any IDL installation. See [“About Hershey Vector Fonts”](#) on page 5730 for additional details.

TrueType Fonts

TrueType fonts, also referred to here as *outline fonts*, are drawn as character outlines, which are filled when displayed. They are largely device-independent, but do have some device-dependent characteristics. Four TrueType font families are included with IDL; these fonts should display in a similar way on any IDL platform. TrueType font support for IDL Object Graphics was introduced in IDL version 5.0 and support in IDL Direct Graphics was introduced in IDL version 5.1. See [“About TrueType Fonts”](#) on page 5732 for additional details.

Device Fonts

Device fonts, also referred to as *hardware fonts*, rely on character-display hardware or software built in to a specific display device, and include PostScript fonts. Device fonts, necessarily, are device-dependent and differ from platform to platform and display device to display device. Device fonts are supported in IDL Direct Graphics. See [“About Device Fonts”](#) on page 5736 for additional details.

Choosing a Font Type

Some of the issues involved in choosing between Hershey vector, TrueType, and device fonts are explained below.

Appearance

Hershey vector-drawn characters are of medium quality, suitable for most uses. TrueType characters are of relatively high quality, although at some point sizes the triangulation process (described in [“About TrueType Fonts”](#) on page 5732) may cause characters to appear slightly jagged. The appearance of device characters varies from mediocre (characters found in many graphics terminals) to publication quality (PostScript).

Three-Dimensional Transformations

Hershey vector or TrueType fonts should always be used with three-dimensional transformations. Both vector and TrueType characters pass through the same transformations as the rest of the plot, yielding a better looking plot. See [“Coordinates of 3-D Graphics”](#) (Chapter 5, *Using IDL*) for more information, and the [“Examples”](#) section of [“T3D”](#) on page 2560 for an example of vector-drawn characters with three-dimensional graphics. Device characters are not subject to the three-dimensional transforms.

Portability

The Hershey vector-drawn fonts work using any graphics device and look the same on every device (within the limitations of device resolution) on any system supported by IDL.

TrueType fonts are available only on the X, WIN, PRINTER, PS, and Z Direct Graphics devices, and in IDL’s Object Graphics system. If you use only the fonts supplied with IDL, TrueType fonts also look the same on every supported device (again within the limits of the device resolution). If you use TrueType fonts other than those supplied with IDL, your font may not be installed on the system which runs your program. In this case, IDL will substitute a known font for the missing font.

The appearance, size, and availability of device fonts varies greatly from device to device. Many, if not most, of the positioning and font changing commands recognized by the Hershey vector-drawing routines are ignored when using device fonts. The exception to this rule is the Direct Graphics PS device; if you use one of the PostScript fonts supported by IDL, the PostScript output from the PS device will be identical between platforms.

Computational Time

Device fonts are generally rendered the most quickly, since the hardware device or operating system handles all computations and caching.

It takes more computer time to draw characters with line vectors and generally results in more input/output. However, this is not an important issue unless the plot contains a large number of characters or the transmission link to the device is very slow.

The initial triangulation step used when displaying TrueType fonts for the first time can be computationally expensive. However, since the font shapes are cached, subsequent uses of the same font are relatively speedy.

Flexibility

Hershey vector-drawn fonts provide a great deal of flexibility. There are many different typefaces available, as shown in the tables at the end of this chapter. In addition, such fonts can be arbitrarily scaled, rotated, and transformed.

TrueType fonts support fewer embedded formatting commands than do the vector fonts, and cannot be scaled, rotated, or transformed.

The abilities of hardware-generated characters differ greatly between devices so it is not possible to make a blanket statement on when they should be used—the best font to use depends on the available hardware. In general, however, the Hershey vector or TrueType fonts are easier to use and often provide superior results to what is available from the hardware. See the discussion of the device you are using in [Appendix A, “IDL Direct Graphics Devices”](#) for details on the hardware-generated characters provided by that device.

Print Quality

For producing publication-quality output, we recommend using either the TrueType font system, or the Direct Graphics PS device and one of the PostScript fonts supported by IDL.

Fonts in IDL Direct vs. Object Graphics

The majority of this section deals with IDL Direct Graphics. However, the Hershey vector and TrueType font systems described here are also available in the IDL Object Graphics system as described in [Chapter 9, “Annotating an Object Display”](#) (*Object Programming*).

IDL Direct Graphics

When generating characters for Direct Graphics plots, IDL uses the font system specified by setting the `!P.FONT` system variable to one of the following values:

-1	Use Hershey vector-drawn fonts—the default
0	Use device fonts (fonts supplied by the graphics device)
1	Use TrueType fonts

The IDL system variable `!P.FONT` setting can be overridden for a single IDL Direct Graphics routine (`AXIS`, `CONTOUR`, `PLOT`, `SHADE_SURF`, `SURFACE`, or `XYOUTS`) by setting the `FONT` keyword equal to -1, 0, or 1.

Once a font system has been selected, an individual font can be chosen either via a formatting command embedded in a text string as described in [“Embedded Formatting Commands”](#) on page 5745, or by setting the value of the `SET_FONT` keyword to the `DEVICE` routine (see [“SET_FONT”](#) on page 5547). Also see [“Using TrueType Fonts”](#) on page 5733 and [“Using Device Fonts”](#) on page 5737 for additional examples of using `SET_FONT`.

IDL Object Graphics

IDL Object Graphics can use the Hershey vector and TrueType font systems. Like Direct Graphics, embedded formatting commands can change the characteristics or position of text within a text string as described in [“Embedded Formatting Commands”](#) on page 5745. TrueType fonts you add to your IDL installation as described in [“About TrueType Fonts”](#) on page 5732 will be available to the Object Graphics system. Device fonts (including PostScript fonts) are unavailable in Object Graphics. See [Chapter 9, “Annotating an Object Display”](#) (*Object Programming*) for information on using creating and using `IDLgrText` and `IDLgrFont` objects.

About Hershey Vector Fonts

The image shows the text "A Hershey Font" rendered in a light gray, thin-lined font style characteristic of Hershey vector fonts. The letters are composed of simple geometric shapes and lines, giving them a clean, technical appearance.

Figure H-10: Hershey Font

The Hershey vector fonts used by IDL were digitized by Dr. A.V. Hershey of the Naval Weapons Laboratory. Characters in the vector fonts are stored as equations, and can be scaled and rotated in three dimensions. They are drawn as lines on the current graphics device, and are displayed quickly and efficiently by IDL. The Hershey vector fonts are built into IDL itself, and are always available.

All the available fonts are illustrated in [“Hershey Vector Font Samples”](#) on page 5760. The default Hershey vector font is Font 3, Simplex Roman.

Using Hershey Vector Fonts

To use the Hershey vector font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to -1 (negative one), or set the `FONT` keyword of one of the Direct Graphics routines equal to -1. The vector font system is the default font system for IDL. To use the vector font system with IDL Object Graphics, consult [“Creating Font Objects”](#) (Chapter 9, *Object Programming*).

Once the vector font system is selected, use an embedded formatting command to select a vector font (or fonts) for each string (see [“Embedded Formatting Commands”](#) on page 5745 for details). The font selected “sticks” from string to string; that is, if you change fonts in one string, future strings will use the new font until you change it again or exit IDL.

For example, to use the Duplex Roman Hershey vector font for the title of a plot, you would use a command that looks like this:

```
PLOT, mydata, TITLE="!5Title of my plot"
```

Also see the following to modify the characteristics of a TrueType font:

- Change font size — see [“Specifying Font Size”](#) on page 5743.
- Change font usage or position — see [“Embedded Formatting Commands”](#) on page 5745. Embedded formatting commands are in-line commands that allow you to position text and change fonts within a single line of text.

ISO Latin 1 Encoding

The default Hershey vector font (Font 3, Simplex Roman) follows the ISO Latin 1 Encoding scheme and contains many international characters. The illustration of this font under [“Hershey Vector Font Samples”](#) on page 5760 can be used to find the octal codes for the special characters.

For example, suppose you want to display some text with an Angstrom symbol in it. Looking at the chart of font 3, we see that the Angstrom symbol has octal code 305. Non-printable characters can be represented in IDL using octal or hexadecimal notation and the `STRING` function (see [“Non-Printing Characters”](#) (Chapter 14, *Application Programming*) for details). So the Angstrom can be printed by inserting a `STRING("305B)` character in the text string as follows:

```
XYOUTS,.1, .5, 'Here is an Angstrom symbol: ' + STRING("305B), $
/NORM, CHARSIZE=3
```

Greek Fonts

Different character sets map greek characters to keyboard keys differently. The Microsoft Windows Symbol font, for example, maps the capital letter Chi (X) to the latin capital C, whereas the Hershey Greek fonts map the capital Gamma (Γ) to the latin capital C. Use the font tables under [“Hershey Vector Font Samples”](#) on page 5760 to determine the mapping between greek and latin character sets.

Customizing the Hershey Vector Fonts

The `EFONT` procedure is a widget application that allows you to edit the Hershey fonts and save the results. Use this routine to add special characters or completely new, custom fonts to the Hershey fonts.

About TrueType Fonts

A TrueType Font

Figure H-11: TrueType Font

Beginning with version 5.2, IDL includes the following five TrueType font families:

Font Family	Italic	Bold	BoldItalic
Courier	Courier Italic	Courier Bold	Courier Bold Italic
Helvetica	Helvetica Italic	Helvetica Bold	Helvetica Bold Italic
Monospace Symbol			
Times	Times Italic	Times Bold	Times Bold Italic
Symbol			

Table H-31: TrueType Font Names

When TrueType fonts are rendered on an IDL graphics device or destination object, the font outlines are first scaled to the proper size. After scaling, IDL converts the character outline information to a set of polygons using a triangulation algorithm. When text in a TrueType font is displayed, IDL is actually drawing a set of polygons calculated from the font information. This process has two side effects:

1. Computation time is used to triangulate and create the polygons. This means that you may notice a slight delay the first time you use text in a particular font and size. Once the polygons have been created, the information is cached by IDL and there is no need to re-triangulate each time text is displayed. Subsequent uses of the same font and size happen quickly.
2. Because the TrueType font outlines are converted into polygons, you may notice some chunkiness in the displayed characters, especially at small point sizes. The smoothness of the characters will vary with the quality of the TrueType font you are using, the point size, and the general smoothness of the font outlines.

Using TrueType Fonts

To use the TrueType font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to 1 (one), or set the `FONT` keyword to on one of the Direct Graphics routines equal to 1. Consult [“Creating Font Objects”](#) (Chapter 9, *Object Programming*) for information on using the TrueType font system with IDL Object Graphics.

Once the TrueType font system is selected, use the `SET_FONT` keyword to the `DEVICE` routine to select the font to use. The value of the `SET_FONT` keyword is a *font name string*. The font name is the name by which IDL knows the font; the names of the TrueType fonts included with IDL are listed under [“About TrueType Fonts”](#) on page 5732. Finally, specify the `TT_FONT` keyword in the call to the `DEVICE` procedure. For example, to use Helvetica Bold Italic, use the following statement:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

To use Times Roman Regular:

```
DEVICE, SET_FONT='Times', /TT_FONT
```

IDL’s default TrueType font is 12 point Helvetica regular.

Also see the following to modify the characteristics of a TrueType font:

- Change font size — see [“Specifying Font Size”](#) on page 5743.
- Change font usage or position — see [“Embedded Formatting Commands”](#) on page 5745. Embedded formatting commands are in-line commands that allow you to position text and change fonts within a single line of text. A subset of the embedded formatting commands available for use with the Hershey vector fonts are also available when using the TrueType font system.

IDL TrueType Font Resource Files

The TrueType font system relies on a resource file named `ttfont.map`, located in the `resource/fonts/tt` subdirectory of the IDL directory. The format of the `ttfont.map` file is:

```
FontName      FileName      DirectGraphicsScale      ObjectGraphicsScale
```

where the fields in each column must be separated by white space (spaces and/or tabs). The fields contain the following information

The *Fontname* field contains the name that would be used for the `SET_FONT` keywords to the `DEVICE` routine.

The *Filename* field contains the name of the TrueType font file. On UNIX platforms, IDL will search for the file specified in the *FileName* field in the current directory (that is, in the `resource/fonts/tt` subdirectory of the IDL directory) if a bare filename is provided, or it will look for the file in the location specified by the fully-qualified file name if a complete path is provided. Because different platforms use different path-specification syntax, we recommend that you place any TrueType font files you wish to add to the `ttfont.map` file in the `resource/fonts/tt` subdirectory of the IDL directory. On Windows platforms, this entry may be `*`, in which case the font will be loaded from the operating system font list, but that the following two scale entries will be honored.

The *DirectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Direct Graphics device. If you want the tallest character in the font to fit exactly within the vertical dimension of the device's current character size (as set via the `SET_CHARACTER_SIZE` keyword to the `DEVICE` procedure, described in [“Specifying Font Size”](#) on page 5743), set the scale factor equal to 1.0. Change the scale factor to a smaller number to scale a smaller portion of the tallest character into the character size.

For example, suppose the tallest character in your font is “ \tilde{A} ”. Setting the scale factor to 1.0 will scale this character to fit the current character size, and then apply the same scaling to all characters in the font. As a result, the letter “M” will fill only approximately 85% of the full height of the character size. To scale the font such that the height of the “M” fills the vertical dimension of the character size, you would include the value 0.85 in the scale field of the `ttfont.map` file.

The *ObjectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Object Graphics device. (This field works just like the *DirectGraphicsScale* field.) This scale factor should be set to 1.0 if the maximum ascent among all glyphs within a given font is to fit exactly within the font size (as set via the `SIZE` property to the `IDLgrFont` object).

Adding Your Own Fonts

To add a your own font to the list of fonts known to IDL, use a text editor to edit the `ttfont.map` file, adding the *FontName*, *FileName*, *DirectGraphicsScale*, and *ObjectGraphicsScale* fields for your font. You will need to restart IDL for the changes to the `ttfont.map` file to take effect. On Windows systems, you can use fonts that are not mentioned in the `ttfont.map` file, as long as they are installed in the Fonts control panel, as described below.

Warning

If you choose to modify the `ttfont.map` file, be sure to keep a backup copy of the original file so you can restore the defaults if necessary. Note also that applications that use text may appear different on different platforms if the scale entries in the `ttfont.map` file have been altered.

Where IDL Searches for Fonts

The TrueType font files included with IDL are located in the `resource/fonts/tt` subdirectory of the IDL directory. When attempting to resolve a font name (specified via the `FONT` keyword to the `DEVICE` procedure), IDL will look in the `ttfont.map` file first. If it fails to find the specified font file in the `ttfont.map` file, it will search for the font file in the following locations:

UNIX

No further search will be performed. If the specified font is not included in the `ttfont.map` file, IDL will substitute Helvetica.

Microsoft Windows

If the specified font is not included in the `ttfont.map` file, IDL will search the list of fonts installed in the system (the fonts installed in the Font control panel). If the specified font is not found, IDL will substitute Helvetica.

Note

To get the list, you can use the following command, which returns in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

About Device Fonts

A PostScript Font

Figure H-12: PostScript Font

Device, or hardware, fonts are fonts that are provided directly by your system's hardware or by software other than IDL. In past releases of IDL, we have used the term "*hardware fonts*" extensively to discuss these types of fonts. This is because in the early days of IDL, computer displays were either text-only terminals or dedicated graphics display devices such as plotters or Tektronix graphics terminals. These graphics displays generally came with a set of fonts built-in; when IDL asked the device to display characters in a built-in font, it was making a request to the hardware to display those characters.

As computer displays have become more sophisticated, the concept of fonts provided "by the hardware" has expanded to include fonts provided by the computer's operating system, or by font-management software. For example, many computers now use font management software like Adobe Type Manager to manage the fonts made available by the operating system to all applications. We use the term "device font" to refer to a font that is available to one of IDL's graphics devices from a source *other than IDL itself*. (In this case, a "graphics device" can be a Direct Graphics device as specified by the DEVICE routine.) While device fonts may include fonts only available because a particular piece of hardware knows how to draw characters in that font (a pen plotter is an example of a device that may still have its own special fonts), in most cases device fonts are fonts supplied by the operating system to any application that may want to use them.

Which Device Fonts Are Available?

To determine which device fonts are available on your system and the exact font strings to specify for each, use the [GET_FONTNAMES](#) keyword to the DEVICE

procedure. Use one of the following operating-system specific methods to determine which fonts are available:

- **UNIX** — on most systems, the `xlsfonts` utility displays a list of fonts available to the operating system.
- **Microsoft Windows** — fonts available to the system are displayed in the Fonts control panel. You may also have other fonts available if you use font-management software such as Adobe Type Manager.

Using Device Fonts

To use the Device font system with IDL Direct Graphics, either set the value of the IDL system variable `!P.FONT` equal to 0 (zero), or set the `FONT` keyword to one of the Direct Graphics routines equal to 0.

Once the Device font system is selected, use the `SET_FONT` keyword to the `DEVICE` routine to select the font to use. Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`. You can use the `xlsfonts` command to list available X Windows fonts.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

Microsoft Windows

The `SET_FONT` keyword should be set to a string with the following form:

```
!P.FONT = 0
DEVICE, SET_FONT="font*modifier1*modifier2*...modifiern"
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply “keywords” that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF

- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = "Garamond*ITALIC*24"
PLOT, FINDGEN(10), TITLE = "IDL Plot"
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size. See “[SET_FONT](#)” on page 5547 for more information.

Note

If you set the output device to PostScript (`SET_PLOT, 'PS'`), attempting to use the (*) delimiter with `SET_PLOT` will cause an error. You must use `SET_PLOT` with specific PostScript font strings as described in the following section.

Fonts and the PostScript Device

A special set of device fonts are available when the current Direct Graphics device is PS (PostScript). IDL includes font metric information for 35 standard PostScript fonts, and can create PostScript language files that include text in these fonts. (The 35 fonts known to IDL are listed in the following table ([Table H-32](#)); these are standard fonts included in memory in the vast majority of modern PostScript printers.) The PostScript font metric files (*.afm files) are located in the `resource/fonts/ps` subdirectory of the IDL directory.

Using PostScript Fonts

To use a PostScript font in your Direct Graphics output, you must first specify that IDL use the device font system, then switch to the PS device, then choose a font using the `SET_FONT` keyword to the `DEVICE` procedure.

The following IDL commands choose the correct font system (0 designates the device font system), set the graphics device, select the font Palatino Roman, open a PostScript file to print to, plot a simple data set, and close the PostScript file:

```
!P.FONT = 0
SET_PLOT, 'PS'
DEVICE, SET_FONT='Palatino-Roman', FILE='testfile.ps'
PLOT, INDGEN(10), TITLE = 'My Palatino Title'
DEVICE, /CLOSE
```

Allowable values for the SET_FONT keyword are listed in the following table.

Note

Subsequent PostScript output will continue to use the font Palatino Roman until you explicitly change the font again, or exit IDL.

Note

When using SET_FONT with the PostScript device on Windows, you cannot use the (*) delimiter to specify font characteristics as described in “[Microsoft Windows](#)” on page 5735. You must use the names shown in the following table, without modifiers.

You can also specify PostScript fonts using a set of keywords to the DEVICE procedure. The keyword combinations for the fonts included with IDL are listed in the following table. For example to use the PostScript font Palatino Bold Italic, you could use either of the following DEVICE commands:

```
DEVICE, SET_FONT = 'Bookman-LightItalic'
DEVICE, /BKMAN, /LIGHT, /ITALIC
```

PostScript Font SET_FONT Value	DEVICE Keywords
AvantGarde-Book	/AVANTGARDE, /BOOK
AvantGarde-BookOblique	/AVANTGARDE, /BOOK, /OBLIQUE
AvantGarde-Demi	/AVANTGARDE, /DEMI
AvantGarde-DemiOblique	/AVANTGARDE, /DEMI, /OBLIQUE
Bookman-Demi	/BKMAN, /DEMI
Bookman-DemiItalic	/BKMAN, /DEMI, /ITALIC

Table H-32: The Standard 35 PostScript Fonts

PostScript Font SET_FONT Value	DEVICE Keywords
Bookman-Light	/BKMAN, /LIGHT
Bookman-LightItalic	/BKMAN, /LIGHT, /ITALIC
Courier	/COURIER
Courier-Bold	/COURIER, /BOLD
Courier-BoldOblique	/COURIER, /BOLD, /OBLIQUE
Courier-Oblique	/COURIER, /OBLIQUE

Times-BoldItalic	/TIMES, /ITALIC, /BOLD
Times-Italic	/TIMES, /ITALIC
Times-Roman	/TIMES
ZapfChancery-MediumItalic	/ZAPFCHANCERY, /MEDIUM, /ITALIC
ZapfDingats	/ZAPFDINGBATS

Table H-32: The Standard 35 PostScript Fonts (Continued)

Changing the PostScript Font Assigned to an Index

You can change the PostScript font assigned to a given font index using the [FONT_INDEX](#) keyword to the DEVICE procedure. Font indices and their use are discussed in “[Embedded Formatting Commands](#)” on page 5745. There is a slot available for a user-defined font (index number 20). However, any index from 3 to 20 can contain a user-defined font. See “[Adding Your Own PostScript Fonts](#)” on page 5742 for details.

After choosing the PostScript device using `SET_PLOT, 'PS'`, you can see which fonts are associated with the available index numbers by typing `HELP, /DEVICE` at the command line. You can add default fonts or user-defined fonts to the font mapping list. In the following example, a font that is not mapped to a font index number by default (but is a standard PostScript font) is associated with index number 20 and used in the plot title.

```
SET_PLOT, 'PS'
!P.FONT=0
DEVICE, SET_FONT = 'ZapfChancery-MediumItalic', FONT_INDEX=20
PLOT, INDGEN(10), TITLE='!20Simple Plot Example'
DEVICE, /CLOSE
```

View the default `idl.ps` file to see the results.

Changing the font index assigned to a font can be useful when changing PostScript fonts in the middle of a text string. For example, the following statements map Palatino Bold Italic to font index 4, and then output text using that font and the Symbol font:

```
; Map the font selected by !4 to be PalatinoBoldItalic:
DEVICE, /PALATINO, /BOLD, /ITALIC, FONT_INDEX=4
```

```
; Output "Alpha :" in PalatinoBoldItalic followed by an  
; Alpha character:  
XYOUTS, .3, .5, /NORMAL, "!4Alpha: !9a", FONT=0, SIZE=5.0
```

Adding Your Own PostScript Fonts

Because the 35 PostScript fonts included with IDL are built in to a PostScript printer's memory, the IDL distribution includes only the font metric files, which provide positioning information. In addition, the `.afm` files used by IDL are specially processed to provide the information in a format IDL expects.

You can add your own PostScript fonts to the list of fonts known to IDL if you have access to the PostScript font file (usually named `font.pfb`) to load into your printer and to the `font.afm` file supplied by Adobe. You can convert the standard `.afm` file into a file IDL understands using the IDL routine [PSAFM](#). Consult the file `README.TXT` in the `resource/fonts/ps` subdirectory of the IDL directory for details on adding PostScript fonts to your system. In general, you will need to do the following:

1. Add the font to the `resource/fonts/ps` subdirectory of the IDL directory using [PSAFM](#).
2. Add an entry for the font to the `fonts.map` file located in the `resource/fonts/ps` directory. You can locate the required fontname by examining the font file in a text editor.
3. Use the font directly by calling it with `SET_FONT` or add it to the list of font mappings using `FONT_INDEX`. See [“Changing the PostScript Font Assigned to an Index”](#) on page 5741 for details.

Controlling Size, Position and Font Use

The way font size is set depends upon the type of font and whether the font is being rendered in Direct or Object Graphics. See one of the followings:

- Direct Graphics — See [“Controlling Size, Position and Font Use”](#) on page 5743
- Object Graphics — See [“Fonts”](#) (Chapter 9, *Object Programming*)

You can control the position of individual characters, and the font with which individual characters in a text string are rendered by using embedded formatting commands. See [“Embedded Formatting Commands”](#) on page 5745 for details.

Specifying Font Size

The size of a device font is specified when the font is defined. See [“Using Device Fonts”](#) on page 5737 for details. The size of a Hershey vector or TrueType font is specified by using the [SET_CHARACTER_SIZE](#) keyword to the `DEVICE` procedure. The `SET_CHARACTER_SIZE` keyword takes a two-element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value $[x, y]$ to the `SET_CHARACTER_SIZE` keyword may produce characters of different sizes in different fonts.

Note

While the first element of the vector specified to `SET_CHARACTER_SIZE` is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word “Hello There” on the screen in Courier Bold Italic, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines. Use `FONT=1` to specify the TrueType font system:

```
DEVICE, SET_FONT='Courier Bold Italic', /TT_FONT, $
SET_CHARACTER_SIZE=[70,90]
```

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', FONT=1
```

The same example can be replicated using Hershey vector fonts. To use a vector font, specify the font using an embedded formatting command (explained in detail in [“Embedded Formatting Commands”](#) on page 5745). For example, to display the text in Triplex Italic, Hershey vector font number 18, use !18 at the beginning of the string. As the vector font system is the default, you do not need to use the FONT keyword to XYOUTS.

```
DEVICE, SET_CHARACTER_SIZE=[70,90]  
XYOUTS, 0.1, 0.5, '!18Hello!CThere'
```

To return to using the default Helvetica font, change !18 to !3:

```
XYOUTS, 0.1, 0.5, '!3Hello!CThere'
```

You can also use the [CHARSIZE](#) keyword to the graphics routines or the [CHARSIZE](#) field of the !P System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note that changing the CHARSIZE adjusts both the character size and the space between lines.

Embedded Formatting Commands

When you use Hershey vector, TrueType, and some device fonts, text strings can include embedded formatting commands that facilitate subscripting, superscripting, and equation formatting. The method used is similar to that developed by Grandle and Nystrom (1980). Embedded formatting commands are always introduced by the exclamation mark, (!). (The string “! !” is used to produce a literal exclamation mark.)

Tip

Set the `ENABLE_FORMATTING` property on the `IDLgrText` object to use formatting commands in Object Graphics.

Note

Embedded formatting commands prefaced by the exclamation mark have no special significance for hardware-generated characters unless the ability is provided by the particular device in use. The IDL PostScript device driver accepts many of the standard embedded formatting commands, and is described here. If you wish to use hardware fonts with IDL Direct Graphics devices other than the PostScript device, consult the description of the device in [Appendix A, “IDL Direct Graphics Devices”](#) before trying to use these commands with hardware characters.

You can determine whether embedded formatting commands are available for use with device fonts on your current graphics device by inspecting bit 12 of the *Flags* field of the `!D`. Use the IDL statement:

```
IF (!D.FLAGS AND 4096) NE 0 THEN PRINT, 'Bit is set.'
```

to determine whether bit 12 of the *Flags* field is set for the current graphics device.

Changing Fonts within a String

You can change fonts one or more times within a text string using the embedded font commands shown in the table below. The character following the exclamation mark can be either upper or lower case.

Examples of commands used to change fonts in mid-string are included in “[Formatting Command Examples](#)” on page 5749.

Command	Hershey Vector Font	TrueType Font	PostScript Font
!3	Simplex Roman (default)	Helvetica	Helvetica
!4	Simplex Greek	Helvetica Bold	Helvetica Bold
!5	Duplex Roman	Helvetica Italic	Helvetica Narrow
!6	Complex Roman	Helvetica Bold Italic	Helvetica Narrow Bold Oblique
!7	Complex Greek	Times	Times Roman
!8	Complex Italic	Times Italic	Times Bold Italic
!9	Math/special characters	Symbol	Symbol
!M	Math/special characters (change effective for one character only)	Symbol	Symbol
!10	Special characters	Symbol *	Zapf Dingbats
!11(!G)	Gothic English	Courier	Courier
!12(!W)	Simplex Script	Courier Italic	Courier Oblique
!13	Complex Script	Courier Bold	Palatino
!14	Gothic Italian	Courier Bold Italic	Palatino Italic
!15	Gothic German	Times Bold	Palatino Bold
!16	Cyrillic	Times Bold Italic	Palatino Bold Italic
!17	Triplex Roman	Helvetica *	Avant Garde Book
!18	Triplex Italic	Helvetica *	New Century Schoolbook
!19		Helvetica *	New Century Schoolbook Bold
!20	Miscellaneous	Helvetica *	Undefined User Font

Table H-33: Embedded Font Selection Commands

Command	Hershey Vector Font	TrueType Font	PostScript Font
!X	Revert to the entry font	Revert to the entry font	Revert to the entry font

* The font assigned to this index may be replaced in a future release of IDL.

Table H-33: Embedded Font Selection Commands (Continued)

Positioning Commands

The positioning and other font-manipulation commands are described in the following table. Examples of commands used to position text are included in [“Formatting Command Examples”](#) on page 5749.

Command	Action
!A	Shift above the division line.
!B	Shift below the division line.
!C	“Carriage return,” begins a new line of text. Shift back to the starting position and down one line. This command also performs an implicit “!N” command, returning to the normal level and character size at the beginning of the new line.
!D	Shift down to the first level subscript and decrease the character size by a factor of 0.62.
!E	Shift up to the exponent level and decrease the character size by a factor of 0.44.
!I	Shift down to the index level and decrease the character size by a factor of 0.44.
!L	Shift down to the second level subscript. Decrease the character size by a factor of 0.62.
!N	Shift back to the normal level and original character size.
!R	Restore position. The current position is set from the top of the saved positions stack.

Table H-34: Vector-Drawn Positioning and Miscellaneous Commands

Command	Action
!S	Save position. The current position is saved on the top of the saved positions stack.
!U	Shift to upper subscript level. Decrease the character size by a factor of 0.62.
!X	Return to the entry font.
!Z(u_0, u_1, \dots, u_n)	<p>Display one or more character glyphs according to their unicode value. Each u_i within the parentheses will be interpreted as a 16-bit hexadecimal unicode value. If more than one unicode value is to be included, the values should be separated by commas.</p> <p>Note - If the specified unicode value does not exist in the current font, IDL will make a substitution and generate errors in the output log. For example, the Symbol font included with IDL is not a unicode font; specifying unicode values will generate errors.</p>
!!	Display the ! symbol.

Table H-34: Vector-Drawn Positioning and Miscellaneous Commands

Tip

See [“Formatting Command Examples”](#) on page 5749 for examples that change the characteristics of fonts within a text string.

Formatting Command Examples

The figure below illustrates the relative positions and effects on character size of the level commands. In this figure, the word “Normal” positioned with the letters “!N” are normal level and size characters.

Figure H-13: Positioning Commands with Hershey Vector Fonts (Top) and TrueType Fonts (Bottom)

The positioning shown was created with the following command:

```
XYOUTS, 0.1, 0.3, SIZE=3, $
'!L!Lower!S!E!Exponent!R!I!Index!N Normal' + $
'!S!E!Exp!R!I!Ind!N!S!U Up!R!D Down!N!S!A Above!R!B Below'
```

Note

See “[Object Graphics Embedded Formatting Examples](#)” (Chapter 9, *Object Programming*) for a similar Object Graphics example.

A Complex Equation

Embedded positioning commands and the Hershey vector font system can be used to create the integral shown below:

$$\int_p^x \rho_i U_i^2 dx$$

Figure H-14: An Integral Created with the Hershey Vector Fonts

The command string used to produce the integral is:

```
XYOUTS, 0, .2, $
  '!MI!S!A!E!8x!R!B!Ip!N !7q!Ii!N!8U!S!E2!R!Ii!NdX', $
  SIZE = 3, /NORMAL
```

Remember that the case of the letter in an embedded command is not important. The string may be broken down into the following components:

!MI

Changes to the math set and draws the integral sign, uppercase I.

!S

Saves the current position on the position stack.

!A!E!8x

Shifts above the division line and to the exponent level, switches to the Complex Italic font (Font 8), and draws the “x.”

!R!B!lp

Restores the position to the position immediately after the integral sign, shifts below the division line to the index level, and draws the “*p*.”

!N !7q

Returns to the normal level, advances one space, shifts to the Complex Greek font (Font 7), and draws the Greek letter rho, which is designated by “*q*” in this set.

!li!N

Shifts to the index level and draws the “*i*” at the index level. Returns to the normal level.

!8U

Shifts to the Complex Italic font (Font 8) and outputs the upper case “*U*.”

!S!E2

Saves the position and draws the exponent “2.”

!R!li

Restores the position and draws the index “*i*.”

!N dx

Returns to the normal level and outputs “*dx*.”

Note

The equation shown in the figure above could not be created so simply using the TrueType font system, because the large integral symbol is broken into two or more characters in the TrueType fonts.

Fraction Example

Many equations contain fractional terms that have a line drawn between numerator and denominator. Using IDL's PLOTS and XYOUTS routines can draw such a line, as shown in the figure below:

$$f(x_i, x_j) = \frac{f(x_i) - f(x_j)}{x_i - x_j}$$

Figure H-15: Example of an Equation with a Fractional Term

The following code creates this example:

```
lhs = '!8f(x!S!Ii!R , x!S!Ij!R ) = !X'
XYOUTS, 0.1, 0.5, lhs, WIDTH = lhs_width, CHARSIZE = 2., /NORMAL
rhs = '!8!S!Af(x!S!Ii!R ) - f(x!S!Ij!R )!R!B x!S!Ii!R - $
      x!S!Ij!R !X'
XYOUTS, 0.1 + lhs_width, 0.5, rhs, CHARSIZE = 2., $
      WIDTH = rhs_width, /NORMAL
PLOTS, [0.1 + lhs_width, 0.1 + lhs_width + rhs_width], $
      [0.51, 0.51], /NORMAL
```

Hershey Vector-Drawn Font Example

IDL uses Hershey vector-drawn fonts when the value of the system variable !P.FONT is -1. This is the default condition. Initially, all characters are drawn using the Simplex Roman font (Font 3). When plotting, font changing commands may be embedded in the title strings keyword arguments (XTITLE, YTITLE, and TITLE) to select other fonts. For example, the following statement uses the Complex Roman font (Font 6) for the x -axis title:

```
PLOT, X, XTITLE = '!6X Axis Title'
```

This font remains in effect until explicitly changed. The order in which the annotations are drawn is main title, x -axis numbers, x -axis title, y -axis numbers, and

y-axis title. Strings to be output also may contain embedded information selecting subscripting, superscripting, plus other features that facilitate equation formatting.

The following statements were used to produce the figure below. They serve as an example of a plot using Hershey vector-drawn characters and of equation formatting.

Figure H-16: Example of a Hershey Vector-drawn Plot

```

; Define an array:
X = FLTARR(128)
; Make a step function:
X[30:40] = 1.0
; Take FFT and magnitude:
X = ABS(FFT(X, 1))
; Produce a log-linear plot. Use the Triplex Roman font for the
; x title (!17), Duplex Roman for the y title (!5), and Triplex
; Italic for the main title (!18). The position keyword is used to
; shrink the plotting window:
PLOT, X[0:64], /YLOG, XTITLE = '!17Frequency', $
      YTITLE = '!5Power', $
      TITLE = '!18Example of Vector Drawn Plot', $
      POSITION = [.2, .2, .9, .6]
; String to produce equation:
SS = '!6F(s) = (2!4p)!e-1/2!n !mi!s!a!e!m' + STRING( "44b) $"
      + '!r!b!i!-!m' + STRING( "44b) + '!nF(x)!e-i2!4p!3xs!ndx'
; Output string over plot. The NOCLIP keyword is needed because
; the previous plot caused the clipping region to shrink:
XYOUTS, 0.1, .75, SS, SIZE = 3, $

```

/NORMAL, /NOCLIP

Note

See [“Object Graphics Embedded Formatting Examples”](#) (Chapter 9, *Object Programming*) for a similar Object Graphics example.

TrueType Font Samples

The following figures show roman versions of the four TrueType font families included with IDL. The character sets for the bold, italic, and bold italic versions of these fonts are the same as the roman versions.

The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 'Helvetica', 'Helvetica', /TT_FONT
```

For more information, see [“SHOWFONT”](#) on page 2372.

Note

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the copyright symbol is octal 251.

TrueType font samples include the following:

- [“Helvetica”](#) on page 5756
- [“Times”](#) on page 5757
- [“Courier”](#) on page 5758

Figure H-20: Symbol

Hershey Vector Font Samples

The following figures show samples of various Hershey vector-drawn fonts. The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 3, 'Simplex Roman'
```

To output this figure to a postscript file, you would use the following commands:

```
SET_PLOT, 'PS'
SHOWFONT, 3, 'Simplex Roman'
DEVICE, /CLOSE
```

For more information, see [“SHOWFONT”](#) on page 2372.

Note

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the “\$” symbol is octal 44.

See the following:

About the API History

This chapter collects information about changes to IDL's *Application Programmer's Interface* (API) — the procedures, functions, object classes, object methods, and other features that make up the IDL language. For each IDL release, we list features that were *added* to IDL and features that were made *obsolete*.

Note

Information about changes is also included at the end of each routine's reference section, in a section titled *Version History*.

What Are Obsolete Features?

To improve the overall quality and functionality of IDL, ITT Visual Information Solutions occasionally replaces existing features with new, improved features. In many cases, existing routines are improved without changing their existing behavior—through improvements of the underlying algorithms, for example, or by adding keyword functionality. In some cases, however, the improved methods are incompatible with the old. In these situations, we consider the routines that we have replaced to be *obsolete*.

For similar reasons, arguments and keywords to existing routines may occasionally become obsolete. In many cases, the functionality activated by the obsolete argument or keyword can be achieved more efficiently using a new argument or keyword. If this is the case, existing code using the obsolete argument or keyword will generally continue to function as it always has, although performance may be better using the new, replacement argument or keyword. In cases where the obsolete argument or keyword activated functionality that is no longer available (perhaps as a result of an operating system upgrade or change), IDL will either quietly ignore the presence of the argument or keyword (if doing so does not affect the resulting output) or warn that an invalid parameter has been specified.

This chapter lists the features that have become obsolete in each version of IDL. These features are not documented along with current IDL routines. To view reference information for features obsoleted in IDL version 5.0 and later, see the *Obsolete IDL Features* guide. Features obsoleted in IDL 4.0 and earlier are not documented in the *Obsolete IDL Features* guide. If a `.pro` file for the routine exists, it is located in the `lib/obsolete` subdirectory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the `DOC_LIBRARY` routine.

Changes in IDL 7.1

- [Features Added in IDL 7.1](#)
- [Features Obsoleted in IDL 7.1](#)

Features Added in IDL 7.1

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
BANDPASS_FILTER	Introduced
BANDREJECT_FILTER	Introduced
CDF_SET_MD5CHECKSUM	Introduced
DEVICE	The DECOMPOSED and GET_DECOMPOSED keywords are now accepted by the PS device.
ESTIMATOR_FILTER	Introduced
FFT	Added the following keywords: CENTER
ICONTOUR , IIMAGE , IMAP , I PLOT , ISURFACE , IVECTOR , IVOLUME	Added the following keywords: CURRENT_ZOOM, DEPTH_CUE_BRIGHT, DEPTH_CUE_DIM, FONT_COLOR, FONT_NAME, FONT_SIZE, FONT_STYLE, STRETCH_TO_FIT, TITLE, WINDOW_TITLE, XMARGIN, YMARGIN, ZOOM_ON_RESIZE Changed behavior of the TITLE keyword to create a text annotation. Titles for the iTool window itself are now created with the WINDOW_TITLE keyword.
ICONVERTCOORD	Introduced

Table I-35: Features Introduced in IDL 7.1

Feature	Description
IDDELETE	Introduced
IDL_BASE64	Introduced
IDLgrText::GetIndexAtCoord	Introduced
IDLgrText::GetIndexRelativeTo	Introduced
IDLgrTextEdit	Introduced
IDLitTool::GetThumbnail	Introduced
IELLIPSE	Introduced
IGETCURRENT	Introduced
IGETCURRENT	Introduced
IGETDATA	Introduced
IGETID	Introduced
IOPEN	Introduced
IPOLYGON	Introduced
IPOLYLINE	Introduced
IPUTDATA	Introduced
IREGISTER	Introduced
IRESET	Introduced
IRESOLVE	Introduced
IROTATE	Introduced
ISAVE	Introduced
ISCALE	Introduced
ISETCURRENT	Introduced
ISETPROPERTY	Introduced
ITEXT	Introduced

Table I-35: Features Introduced in IDL 7.1

Feature	Description
ITRANSLATE	Introduced
IZOOM	Introduced
LEAST_SQUARES_FILTER	Introduced
MAKE_DLL	Added the following keywords: PLATFORM_EXTENSION
MAKE_RT	Added the following keywords: OVERWRITE, SUNX86_64
MAP_PROJ_INIT	Added the following keywords: ELLIPSOID (replaces the DATUM keyword.)
MEAN_FILTER	Introduced
MOMENT	Added the following keywords: MAXMOMENT
OBJ_ISA	Now accepts string class names in addition to object references when performing inheritance test.
QUERY_CSV	Introduced
READ_CSV	Introduced
WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST	Added the following keywords: FLAT
WIENER_FILTER	Introduced
WRITE_CSV	Introduced
WRITE_TIFF	Added the following keywords: COMPLEX, DCOMPLEX, DOUBLE, L64, SIGNED

Table I-35: Features Introduced in IDL 7.1

Features Obsoleted in IDL 7.1

The following features were present in IDL Version 7.0 but became obsolete in IDL Version 7.1.

Routine	Replaced by	.pro File?
ITGETCURRENT	IGETCURRENT	itgetcurrent.pro
ITCURRENT	ISETCURRENT	itcurrent.pro
ITDELETE	IDDELETE	itdelete.pro
ITREGISTER	IREGISTER	itregister.pro
ITRESET	IRESET	itreset.pro
ITRESOLVE	IRESOLVE	itresolve.pro

Table I-36: Routines Obsoleted in IDL 7.1

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
IMAP	DATUM keyword	This keyword has been replaced by the ELLIPSOID keyword.
LMGR	CLIENTSERVER keyword	This keyword has been deprecated.
MAP_PROJ_INIT	DATUM keyword	This keyword has been replaced by the ELLIPSOID keyword.

Table I-37: Arguments and Keywords Obsoleted in IDL 7.1

Changes in IDL 7.0

- [Features Added in IDL 7.0](#)
- [Features Obsoleted in IDL 7.0](#)

Features Added in IDL 7.0

Note

The *IDL Workbench* graphical interface to IDL replaced the IDL Development Environment in version 7.0.

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
GET_LOGIN_INFO	Introduced
IDLgrBuffer::QueryRequiredTiles IDLgrClipboard::QueryRequiredTiles IDLgrPrinter::QueryRequiredTiles IDLgrWindow::QueryRequiredTiles	Added the following keywords: PATH
MAKE_RT	Introduced
PROFILER	Added the following keywords: FILENAME
ROUTINE_FILEPATH	Introduced

Table I-38: Features Introduced in IDL 7.0

Features Obsoleted in IDL 7.0

In the transition from the pre-version 7.0 development environments to the IDL Workbench, we have tried to replicate or enhance the features you've come to expect from IDL. In some cases, however, we have altered or deprecated existing functionality. Specifically:

IDLDE Macros

The IDL Development Environment macro capability is no longer available. In some limited cases, IDL Workbench code templates may provide a substitute.

GUI Builder

The IDL GUI Builder is no longer included. The GUI Builder was a Windows-only feature that did not interoperate with the IDL Workbench.

Projects

The pre-version 7.0 *IDL Projects* mechanism has been replaced by a new IDL Workbench project mechanism based on Eclipse features. See the [Working with Projects](#) tutorial for additional information.

Runtime Distribution Export

The ability to export an IDL runtime distribution using the project mechanism is no longer available. While we hope to add the ability to create an IDL runtime distribution to the IDL Workbench in a future release, we have added a utility routine, [MAKE_RT](#), to allow you to create runtime distributions from the IDL command line.

X Window System Resources

Previous versions of IDL used the values of numerous X Window System resources to modify the appearance and behavior of the Motif IDL Development Environment. The relevant resources were prefaced with the identifier `Idl*idlde`; they were defined in a system-wide resource file

```
<IDL_DIR>/resource/X11/lib/app-defaults/Idl
```

and in individual users' `~/.idlde` files.

With the switch to the Eclipse-based IDL Workbench, all of the Motif IDLDE X resources are obsolete, and have been removed from the `Idl` resource file. Individual users' `~/.idlde` files will no longer be read when IDL starts up. Flags specifying the values of X resources are no longer accepted at the UNIX command line when launching IDL.

X resources that apply to IDL widgets and graphics windows are still used. These resources are prefaced with the identifier `Idl*` (no `idlde`). The system-wide `Idl` resource file is still present, and individual users can modify the `~/.Xdefaults` file to contain resource definitions for the `Idl*` resources.

Preferences and Preference Migration

Beginning with IDL 7.0, PREF_MIGRATE is no longer called automatically the first time IDL is run. You can still use PREF_MIGRATE to manually migrate IDL system preferences. IDL Workbench preferences are managed separately, by the workbench itself. For more on the difference between system and workbench preferences, see [“About IDL System Preferences”](#) on page 5684.

The following IDL system preferences are no longer supported. Most of the obsolete preferences are replaced by IDL Workbench preferences. As a result, these values can be set within the IDL Workbench interface via the **Preferences** dialog, but not from within IDL using the IDL system preferences mechanism.

All of the obsolete IDE preferences have the prefix IDL_MDE (Motif Development Environment) or IDL_WDE (Windows Development Environment). The table below lists all of the obsolete IDE preferences along with the IDL Workbench equivalents, if any. Note that although an IDE preference may have only been available for one of the two Development Environments, the IDL Workbench equivalents are valid on all IDL platforms.

Obsolete IDE Preference	IDL Workbench Equivalent
IDL_MDE_EDIT_BACKUP IDL_WDE_EDIT_BACKUP	The local history of a file is maintained when you create or modify a file. Each time you edit and save a file, a copy of it is saved. This allows you to replace the file with a previous state.
IDL_WDE_EDIT_[B F]COLOR_*	The background and foreground colors for various categories of text are set in the Preferences dialog, in the IDL > Syntax Coloring section.
IDL_WDE_EDIT_CHROMACODE	None.
IDL_MDE_EDIT_COMPILE_OPTION IDL_WDE_EDIT_COMPILE_OPTION	<ol style="list-style-type: none"> <li data-bbox="663 1229 1096 1291">1. In the Preferences dialog, select IDL > Editor. <li data-bbox="663 1308 1214 1407">2. Select Enable Compile on Save to automatically compile files when you save them.

Table I-39: IDLDE Preferences Obsolete in IDL 7.0.

Obsolete IDE Preference	IDL Workbench Equivalent
IDL_MDE_EDIT_CWD IDL_WDE_EDIT_CWD	<p>To change the IDL process' current working directory to the directory containing the file just opened:</p> <ol style="list-style-type: none"> 1. In the Preferences dialog, select IDL > Editor. 2. Select Change directory on file open. 3. Click OK.
IDL_WDE_EDIT_FONT	<p>The general editor font is set in the Colors and Fonts section of the Preferences dialog.</p> <p>To set the general editor font:</p> <ol style="list-style-type: none"> 1. In the Preferences dialog, select General > Appearance > Colors and Fonts. 2. Open the Basic folder and select Text Font. 3. Click Change. 4. On the Font dialog, choose the font options. 5. Click OK on both dialogs.
IDL_WDE_EDIT_OPEN_ON_DEBUG	<p>None.</p> <p>Note - When execution halts due to an error, the file and line number at which the error occurred are shown in the Console view as a hyperlink. Clicking the link opens the file automatically.</p>
IDL_MDE_EDIT_READONLY IDL_WDE_EDIT_READONLY	<ol style="list-style-type: none"> 1. In the Project Explorer view, right-click a file and select Properties. 2. On the Properties dialog, select Read only. 3. Click OK.

Table I-39: IDLDE Preferences Obsoleted in IDL 7.0. (Continued)

Obsolete IDE Preference	IDL Workbench Equivalent
IDL_WDE_EDIT_TAB_ENABLE	<p>To determine whether a tab character or spaces are inserted when pressing the Tab key in the IDL editor:</p> <ol style="list-style-type: none"> 1. In the Preferences dialog, select IDL > Editor. 2. If you don't want to use tab characters, select Use spaces instead of tabs. 3. Click OK.
IDL_WDE_EDIT_TAB_SP_ON_SAVE	None.
IDL_WDE_EDIT_TAB_WIDTH	<p>To set the number of spaces used to display a tab character:</p> <ol style="list-style-type: none"> 1. In the Preferences dialog, select IDL > Editor. 2. Change the Displayed tab width value. 3. Click OK.
IDL_MDE_EXIT_CONFIRM IDL_WDE_EXIT_CONFIRM	<p>To exit the Workbench, select File > Exit from the menu bar or close the workbench with the window close button (x). When the latter option is used a prompt will ask if you really wish to exit the Workbench.</p> <p>To enable or disable the exit prompt:</p> <ol style="list-style-type: none"> 1. Select Window > Preferences. 2. On the Preferences dialog, select General > Startup and Shutdown. 3. Select Confirm exit when closing last window. 4. Click OK.

Table I-39: IDLDE Preferences Obsoleted in IDL 7.0. (Continued)

Obsolete IDE Preference	IDL Workbench Equivalent
IDL_WDE_INPUT_FONT	<p>To set the command line font:</p> <ol style="list-style-type: none"> 1. Select Window > Preferences. 2. On the Preferences dialog, select General > Appearance > Colors and Fonts. 3. Open the IDL folder and select Command Line font. 4. Click Change. 5. On the Font dialog, choose the font options. 6. Click OK on both dialogs.
IDL_WDE_LOG_FONT	<p>To set the Console view font:</p> <ol style="list-style-type: none"> 1. Select Window > Preferences. 2. On the Preferences dialog, select General > Appearance > Colors and Fonts. 3. Open the Debug folder and select Console font. 4. Click Change. 5. On the Font dialog, choose the font options. 6. Click OK on both dialogs.
IDL_MDE_LOG_LINES IDL_WDE_LOG_LINES	<p>You cannot control the number of lines written to the Console view, but you can set the maximum number of characters written:</p> <ol style="list-style-type: none"> 1. Select Window > Preferences. 2. On the Preferences dialog, select Run/Debug > Console. 3. Select Limit console output. 4. Enter a Console buffer size (in characters). 5. Click OK.
IDL_MDE_LOG_TRIM IDL_WDE_LOG_TRIM	None.

Table I-39: IDLDE Preferences Obsolete in IDL 7.0. (Continued)

Obsolete IDE Preference	IDL Workbench Equivalent
IDL_MDE_SPLASHSCREEN IDL_WDE_SPLASHSCREEN	None.
IDL_MDE_START_DIR IDL_WDE_START_DIR	<p>These preferences are replaced by the IDL_START_DIR preference.</p> <p>To set the IDL_START_DIR preference, either use the PREF_SET routine or the IDL Workbench Preferences dialog:</p> <ol style="list-style-type: none"> 1. In the Preferences dialog, select IDL. 2. Type a directory in the Initial working directory box, or browse for a directory. 3. Click OK.

Table I-39: IDLDE Preferences Obsolete in IDL 7.0. (Continued)

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
PREF_MIGRATE	MACRO and STARTUP keywords	These keywords are not used by the IDL Workbench

Table I-40: Arguments and Keywords Obsolete in IDL 7.0

Changes in IDL 6.4

- [Features Added in IDL 6.4](#)
- [Features Obsoleted in IDL 6.4](#)

Features Added in IDL 6.4

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
CDF_EPOCH_COMPARE	Introduced
CDF_EPOCH_DIFF	Introduced
COLOR_CONVERT	Added the following keywords: YUV_RGB, YIQ_RGB, YPBPR_RGB, YCBCR_RGB, RGB_YUV, RGB_YIQ, RGB_YPBPR, RGB_YCBCR, INTERLEAVE
COLOR_EXCHANGE	Introduced
COLOR_RANGE_MAP	Introduced
COLORIZE_SAMPLE	Introduced
COLORMAP_GRADIENT	Introduced
COLORMAP_ROTATION	Introduced
COMFIT	Added the following keywords: CHISQ, DOUBLE, ITER, ITMAX, STATUS, TOL, YERROR
CW_ANIMATE	Added the following keywords: MPEG_BITRATE, MPEG_FORMAT, MPEG_QUALITY

Table I-41: Features Introduced in IDL 6.4

Feature	Description
DEVICE	Added the following keywords: GET_PIXEL_DEPTH, SET_PIXEL_DEPTH The following keywords now apply to the Z-buffer device: DECOMPOSED, GET_DECOMPOSED, GET_WRITE_MASK, SET_WRITE_MASK
EDGE_DOG	Introduced
EMBOSS	Introduced
ICONTOUR	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, INSERT_COLORBAR, INSERT_LEGEND, MAX_VALUE, MIN_VALUE, RENDERER, SCALE_ISOTROPIC, TRANSPARENCY, VIEW_ZOOM, [XYZ]LOG
IDLffXMLDOMDocument::Init	Added the following keywords: STRING
IDLffXMLDOMDocument::Load	Added the following keywords: STRING
IDLffXMLDOMDocument::Save	Added the following keywords: STRING
IDLffXMLSAX::ParseFile	Added the following keywords: URL, XML_STRING
IDLgrAxis	Added the following properties: SHADER
IDLgrClipboard::Draw	Added the following keywords: ISOLATIN1
IDLgrContour	Added the following properties: SHADER
IDLgrFilterChain	Introduced

Table I-41: Features Introduced in IDL 6.4

Feature	Description
IDLgrImage	Added the following properties: IMAGE_1D, INTERNAL_DATA_TYPE , SHADER, TILE_BORDER_SIZE
IDLgrImage::ReadFilteredData	Introduced
IDLgrImage::TileDataLoaded	Introduced
IDLgrLight	Added the following properties: LIGHT_INDEX, SHADER
IDLgrPlot	Added the following properties: SHADER
IDLgrPlot::GetVertexAttributeData	Introduced
IDLgrPlot::SetVertexAttributeData	Introduced
IDLgrPolygon	Added the following properties: SHADER
IDLgrPolygon::GetMultiTextureCoord	Introduced
IDLgrPolygon::GetVertexAttributeData	Introduced
IDLgrPolygon::SetMultiTextureCoord	Introduced
IDLgrPolygon::SetVertexAttributeData	Introduced
IDLgrPolyline	Added the following properties: SHADER
IDLgrPolyline::GetVertexAttributeData	Introduced
IDLgrPolyline::SetVertexAttributeData	Introduced
IDLgrROI	Added the following properties: SHADER
IDLgrROIGroup	Added the following properties: SHADER
IDLgrROIGroup::Remove	Introduced
IDLgrShader	Introduced

Table I-41: Features Introduced in IDL 6.4

Feature	Description
IDLgrShaderBytscl	Introduced
IDLgrShaderConvolve3	Introduced
IDLgrSurface::GetMultiTextureCoord	Introduced
IDLgrSurface::GetVertexAttributeData	Introduced
IDLgrSurface::SetMultiTextureCoord	Introduced
IDLgrSurface::SetVertexAttributeData	Introduced
IDLgrText	Added the following properties: SHADER
IDLgrVolume	Added the following properties: SHADER
IDLgrWindow::GetDeviceInfo	Added the following keywords: FRAME_OBJECT_EXTENSION, MAX_FRAGMENT_UNIFORM_CONSTANT, MAX_TEXTURE_IMAGE_UNITS, MAX_VERTEX_ATTRIBUTES, MAX_VERTEX_TEXTURE_IMAGE_UNITS, MAX_VERTEX_UNIFORM_CONSTANTS, SHADING_LANGUAGE_VERSION
IDLgrWindow::OnWheel	Introduced
IDLitComponent::GetProperty	Added the following keywords: NO_COPY
IDLitComponent::SetProperty	Added the following keywords: NO_COPY
IDLitDirectWindow::OnWheel	Introduced
IDLitManipulator::OnWheel	Introduced
IDLitManipulatorContainer::OnWheel	Introduced

Table I-41: Features Introduced in IDL 6.4

Feature	Description
IDLITSYS_CREATETOOL	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, RENDERER, SCALE_ISOTROPIC
IDLitWindow::AddWindowEventObserver	This method now supports the observation of events generated by the mouse scroll wheel (wheel events).
IDLitWindow::GetEventMask	This method now supports the observation of events generated by the mouse scroll wheel (wheel events).
IDLitWindow::OnWheel	Introduced
IDLitWindow::SetEventMask	This method now supports the observation of events generated by the mouse scroll wheel (wheel events).
IDLnetOGCWCS	Introduced
IDLnetOGCWMS	Introduced
IDLnetURL	Introduced
IIMAGE	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, INSERT_COLORBAR, RENDERER, SCALE_ISOTROPIC, TRANSPARENCY, VIEW_ZOOM
IMAP	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, GEOTIFF, RENDERER, SCALE_ISOTROPIC, VIEW_ZOOM

Table I-41: Features Introduced in IDL 6.4

Feature	Description
IPLOT	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, INSERT_COLORBAR, INSERT_LEGEND, RENDERER, SCALE_ISOTROPIC. SYM_OBJECT, TRANSPARENCY, VIEW_ZOOM
ISURFACE	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, INSERT_COLORBAR, INSERT_LEGEND, MAX_VALUE, MIN_VALUE, RENDERER, SCALE_ISOTROPIC, TRANSPARENCY, VIEW_ZOOM, [XYZ]LOG
IVECTOR	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, INSERT_COLORBAR, RENDERER, SCALE_ISOTROPIC, SYM_COLOR, SYM_INDEX, SYM_SIZE, TRANSPARENCY, USE_DEFAULT_COLOR, VIEW_ZOOM, [XYZ]LOG
IVOLUME	Added the following keywords: ANISTROPIC_SCALE_2D, ANISTROPIC_SCALE_3D, FIT_TO_VIEW, INSERT_COLORBAR, RENDERER, SCALE_ISOTROPIC, VIEW_ZOOM
LAPLACIAN	Introduced
LOADCT	Added the following keyword: RGB_TABLE
NOISE_HURL	Introduced
NOISE_PICK	Introduced

Table I-41: Features Introduced in IDL 6.4

Feature	Description
NOISE_SCATTER	Introduced
NOISE_SLUR	Introduced
OBJ_HASMETHOD	Introduced
PREWITT	Introduced
READ_GIF	Added the following keywords: BACKGROUND_COLOR, DELAY_TIME, DISPOSAL_METHOD, REPEAT_COUNT, TRANSPARENT, USER_INPUT
SHIFT_DIFF	Introduced
WIDGET_BASE	Added the following keywords: BITMAP , MASK
WRITE_GIF	Added the following keywords: BACKGROUND_COLOR, DELAY_TIME, DISPOSAL_METHOD, REPEAT_COUNT, TRANSPARENT, USER_INPUT
XINTERANIMATE	Added the following keyword: MPEG_FORMAT

Table I-41: Features Introduced in IDL 6.4

Features Obsolete in IDL 6.4

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
IVECTOR	MARK_POINTS keyword	This keyword has been replaced by the SYM_INDEX keyword.

Table I-42: Arguments and Keywords Obsolete in IDL 6.4

Changes in IDL 6.3

- [Features Added in IDL 6.3](#)
- [Features Obsoleted in IDL 6.3](#)

Features Added in IDL 6.3

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
BUTTERWORTH	Introduced
CANNY	Introduced
CDF_ATTGET	Enhanced to support the EPOCH16 variable type
CDF_CREATE	Modified to create single-file CDF files by default
CDF_ENCODE_EPOCH16	Introduced
CDF_EPOCH16	Introduced
CDF_PARSE_EPOCH16	Introduced
CDF_SET_CDF27_BACKWARD_COMPATIBLE	Introduced
CDF_VARCREATE	Enhanced to support the EPOCH16 variable type
H5A_READ	Added optional argument: <i>Datatype_ID</i>
H5D_READ	Added optional argument: <i>Datatype_ID</i>
H5T_COMPOUND_CREATE	Introduced
H5T_ENUM_CREATE	Introduced

Table I-43: Features Introduced in IDL 6.3

Feature	Description
H5T_ENUM_GET_DATA	Introduced
H5T_ENUM_INSERT	Introduced
H5T_ENUM_NAMEOF	Introduced
H5T_ENUM_SET_DATA	Introduced
H5T_ENUM_VALUEOF	Introduced
H5T_ENUM_VALUES_TO_NAMES	Introduced
H5T_GET_MEMBER_INDEX	Introduced
H5T_GET_MEMBER_NAME	Enhanced to support enumeration datatypes
H5T_GET_MEMBER_VALUE	Introduced
H5T_GET_TAG	Introduced
H5T_IDL_CREATE	Added the following keywords: OPAQUE
H5T_SET_TAG	Introduced
H5T_STR_TO_VLEN	Introduced
H5T_VLEN_CREATE	Introduced
H5T_VLEN_TO_STR	Introduced
IDL_IDLBridge	Introduced
IDLffDicomExCfg	Introduced
IDLffDicomExQuery	Introduced
IDLffDicomExStorScu	Introduced
IDLffMJPEG2000	Introduced
IDLgrWindow::OnEnter	Introduced
IDLgrWindow::OnExit	Introduced
IDLgrWindow::OnExpose	Introduced
IDLgrWindow::OnKeyboard	Introduced

Table I-43: Features Introduced in IDL 6.3

Feature	Description
IDLgrWindow::OnMouseDown	Introduced
IDLgrWindow::OnMouseMove	Introduced
IDLgrWindow::OnMouseUp	Introduced
IDLgrWindow::OnResize	Introduced
IDLitComponent::NotifyBridge	Introduced
IDLitDirectWindow	Introduced
IDLitWindow::OnEnter	Introduced
IDLitWindow::OnExit	Introduced
IDLitWindow::OnExpose	Introduced
IDLitWindow::OnResize	Introduced
IDLsysMonitorInfo	Introduced
IR_FILTER	Introduced
IVECTOR	Introduced
PRIMES	Introduced
SEM_CREATE	Introduced
SEM_DELETE	Introduced
SEM_LOCK	Introduced
SEM_RELEASE	Introduced
WIDGET_CONTROL	Added the following keywords: SET_DRAG_NOTIFY, SET_DRAGGABLE, SET_DROP_EVENTS, SET_MASK, SET_TREE_INDEX
WIDGET_DRAW	Added the following keywords: DRAG_NOTIFY, DROP_EVENTS
WIDGET_TREE_MOVE	Introduced

Table I-43: Features Introduced in IDL 6.3

Features Obsoleted in IDL 6.3

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
WIDGET_TREE	TOP keyword	This keyword has been replaced by the INDEX keyword.

Table I-44: Arguments and Keywords Obsoleted in IDL 6.3

Changes in IDL 6.2

- [Features Added in IDL 6.2](#)
- [Features Obsoleted in IDL 6.2](#)

Features Added in IDL 6.2

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
BIT_FFS	Introduced
BIT_POPULATION	Introduced
CMYK_CONVERT	Introduced
COMMAND_LINE_ARGS	Introduced
CONVOL	Added the following keywords: BIAS, EDGE_ZERO, INVALID, NORMALIZE
DIALOG_MESSAGE	Added the following keywords: CENTER
DICOMEX_GETCONFIGFILEPATH	Introduced
DICOMEX_GETSTORSCPDIR	Introduced
DICOMEX_NET	Introduced
FILE_POLL_INPUT	Introduced
GET_KBRD	Added the following keywords: ESCAPE, KEY_NAME Omitting the <i>Wait</i> argument is now equivalent to setting it to a non-zero value.
HEAP_NOSAVE	Introduced
HEAP_SAVE	Introduced

Table I-45: Features Introduced in IDL 6.2

Feature	Description
HELP	Added the following keywords: PREFERENCES
ICONTOUR	Added the following keywords: DISABLE_SPLASH_SCREEN, VIEW_TITLE
IDLffJPEG2000	Added the following properties: BIT_RATE, UUIDS
IDLffJPEG2000::GetUUID	Introduced
IDLffJPEG2000::SetUUID	Introduced
IDLffXMLDOMDocument	Added the following properties: NODE_DESTRUCTION_POLICY
IDLffXMLDOMDocument::CreateNodeIterator	Introduced
IDLffXMLDOMDocument::CreateTreeWalker	Introduced
IDLffXMLDOMDocument::Init	Added the following keywords: SCHEMA_CHECKING
IDLffXMLDOMDocument::Load	Added the following keywords: SCHEMA_CHECKING
IDLffXMLDOMDocument::Save	Added the following keywords: ENCODING
IDLffXMLDOMNodeIterator	Introduced
IDLffXMLDOMTreeWalker	Introduced
IDLgrBuffer::GetDeviceInfo	Added the following keywords: MAX_TILE_DIMENSIONS
IDLgrBuffer::QueryRequiredTiles	Introduced
IDLgrClipboard::GetDeviceInfo	Added the following keywords: MAX_TILE_DIMENSIONS
IDLgrClipboard::QueryRequiredTiles	Introduced

Table I-45: Features Introduced in IDL 6.2

Feature	Description
IDLgrImage	Added the following properties: ALPHA_CHANNEL, DEPTH_OFFSET, RENDER_METHOD, TILE_COLOR, TILE_CURRENT_LEVEL, TILE_DIMENSIONS, TILE_LEVEL_MODE, TILE_NUM_LEVELS, TILED_IMAGE_DIMENSIONS, TILING, TRANSFORM_MODE
IDLgrImage::DeleteTileData	Introduced
IDLgrImage::SetTileData	Introduced
IDLgrModel	Added the following properties: ACTIVE_POSITION, RENDER_METHOD
IDLgrPrinter::QueryRequiredTiles	Introduced
IDLgrWindow	Added the following properties: VIEWPORT_DIMENSIONS
IDLgrWindow::GetDeviceInfo	Added the following keywords: MAX_TILE_DIMENSIONS
IDLgrWindow::QueryRequiredTiles	Introduced
IDLitCommand	Added the following properties: SKIP_REDO, SKIP_UNDO
IDLitContainer::AddByIdentifier	Added the following keywords: FOLDER_CLASSNAME
IDLitDataOperation	Added the following properties: WITHIN_UI
IDLitOperation::QueryAvailability	Introduced
IDLitReader::Init	This method's <i>Extensions</i> argument is now optional.

Table I-45: Features Introduced in IDL 6.2

Feature	Description
IDLITSYS_CREATETOOL	Added the following keywords: DISABLE_SPLASH_SCREEN, USER_INTERFACE
IDLitWindow::GetEventMask	Added the following keywords: TIMER_EVENTS
IDLitWindow::OnTimer	Introduced
IDLitWindow::SetEventMask	Added the following keywords: TIMER_EVENTS
IDLitWindow::SetTimerInterval	Introduced
IDLitWriter::Init	This method's <i>Extensions</i> argument is now optional.
IIMAGE	Added the following keywords: DISABLE_SPLASH_SCREEN, VIEW_TITLE
IMAP	Added the following keywords: DISABLE_SPLASH_SCREEN, VIEW_TITLE
IPLOT	Added the following keywords: DISABLE_SPLASH_SCREEN, VIEW_TITLE
ISURFACE	Added the following keywords: DISABLE_SPLASH_SCREEN, VIEW_TITLE
IVOLUME	Added the following keywords: DISABLE_SPLASH_SCREEN, VIEW_TITLE
MAP_PROJ_FORWARD	Added the following keywords: Thread pool keywords
MAP_PROJ_IMAGE	Added the following keywords: XINDEX, YINDEX

Table I-45: Features Introduced in IDL 6.2

Feature	Description
MAP_PROJ_INVERSE	Added the following keywords: Thread pool keywords
POLYFILLV	The subscripts returned will be LONG64 values if the dimensions of the input array warrant that size for proper addressing.
PREF_COMMIT	Introduced
PREF_GET	Introduced
PREF_MIGRATE	Introduced
PREF_SET	Introduced
QUERY_ASCII	Introduced
QUERY_DICOM	Added the following keywords: DICOMEX
READ_DICOM	Added the following keywords: DICOMEX
SAVE	Added the following keywords: EMBEDDED
SCOPE_TRACEBACK	Introduced
WIDGET_CONTROL	Added the following keywords: BACKGROUND_COLOR, DRAW_WHEEL_EVENTS, FONT, FOREGROUND_COLOR, IGNORE_ACCELERATORS The EDITABLE, ROW_HEIGHTS, SET_TABLE_SELECT, and USE_TABLE_SELECT keywords were enhanced to take advantage of the cell- attributes functionality of table widgets.
WIDGET_DRAW	Added the following keywords: WHEEL_EVENTS

Table I-45: Features Introduced in IDL 6.2

Feature	Description
WIDGET_INFO	Added the following keywords: DRAW_WHEEL_EVENTS, STRING_SIZE, TABLE_BACKGROUND_COLOR, TABLE_FONT, TABLE_FOREGROUND_COLOR The ROW_HEIGHTS, TABLE_EDITABLE, and USE_TABLE_SELECT keywords were enhanced to take advantage of the cell- attributes functionality of table widgets.
WIDGET_TABLE	Added the following keywords: BACKGROUND_COLOR, EDITABLE, FONT, FOREGROUND_COLOR, The ROW_HEIGHTS keyword was enhanced to take advantage of the cell- attributes functionality of table widgets.
XDISPLAYFILE	Added the following keywords: GROW_TO_SCREEN, RETURN_ID

Table I-45: Features Introduced in IDL 6.2

Features Obsoleted in IDL 6.2

The following features were present in IDL Version 6.1 but became obsolete in IDL Version 6.2.

Routine	Replaced by	.pro File?
ONLINE_HELP_PDF_INDEX	Nothing: the IDL-Acrobat plugin is no longer supported	
SETUP_KEYS	Nothing; no longer needed	

Table I-46: Routines Obsoleted in IDL 6.2

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
HELP	ALL_KEYS keyword	This keyword was replaced by the combination of the KEYS and FULL keywords.
	CALLS keyword	This keyword was replaced by (is now equivalent to) the use of the REVERSE and SCOPE_TRACEBACK routines together.
IDLitTool::RegisterOperation	DISABLE keyword	This keyword has been replaced by the IDLitOperation::QueryAvailability method.
ONLINE_HELP	HTML_HELP keyword	This keyword is no longer necessary; ONLINE_HELP parses the value of the BOOK keyword to determine file type.
	FOLD_CASE keyword	This keyword is no longer necessary; ONLINE_HELP tries to use both the specified case and upper-case versions of the <i>Value</i> string.
	PAGE keyword	This keyword is used by the obsolete IDL-Acrobat plugin.
	SUPPRESS_PLUGIN_ERRORS keyword	This keyword is used by the obsolete IDL-Acrobat plugin.
	TOPICS keyword	This keyword does not work with Microsoft HTML Help (*.chm) files.

Table I-47: Arguments and Keywords Obsoleted in IDL 6.2

Routine	Argument or Keyword	Description
WIDGET_CONTROL	CANCEL_BUTTON keyword	Cross-platform UI-toolkit support for this keyword is not available.
	DEFAULT_BUTTON keyword	Cross-platform UI-toolkit support for this keyword is not available.

Table I-47: Arguments and Keywords Obsoleted in IDL 6.2 (Continued)

Changes in IDL 6.1

- [Features Added in IDL 6.1](#)
- [Features Obsoleted in IDL 6.1](#)

Features Added in IDL 6.1

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
APP_USER_DIR	Introduced
APP_USER_DIR_QUERY	Introduced
BESELI , BESELJ , BESELK , and BESELY	BESSEL* functions can now handle negative inputs and return complex results.
BILINEAR	Added the following keywords: MISSING.
CLUSTER_TREE	Introduced
COND	Now supports complex data.
CPU	Added the following keywords: RESET, RESTORE
CREATE_CURSOR	Introduced
CREATE_STRUCT	Added the following keywords: NAME
CW_ANIMATE	Added the following keywords: TAB_MODE
CW_ARCBALL	Added the following keywords: TAB_MODE
CW_BGROUP	Added the following keywords: TAB_MODE

Table I-48: Features Introduced in IDL 6.1

Feature	Description
CW_CLR_INDEX	Added the following keywords: TAB_MODE
CW_COLORSEL	Added the following keywords: TAB_MODE
CW_DEFROI	Added the following keywords: TAB_MODE
CW_FIELD	Added the following keywords: TAB_MODE
CW_FILESEL	Added the following keywords: TAB_MODE
CW_FORM	Added the following keywords: TAB_MODE
CW_FSLIDER	Added the following keywords: TAB_MODE
CW_LIGHT_EDITOR	Added the following keywords: TAB_MODE
CW_ORIENT	Added the following keywords: TAB_MODE
CW_PALETTE_EDITOR	Added the following keywords: TAB_MODE
CW_PDMENU	Added the following keywords: TAB_MODE
CW_RGBSLIDER	Added the following keywords: TAB_MODE
CW_TMPL	Added the following keywords: TAB_MODE
CW_ZOOM	Added the following keywords: TAB_MODE
DENDRO_PLOT	Introduced

Table I-48: Features Introduced in IDL 6.1

Feature	Description
DENDROGRAM	Introduced
DEVICE	Added the following keywords: CMYK
DISTANCE_MEASURE	Introduced
EXECUTE	Added the following argument: <i>QuietExecution</i>
FILE_SEARCH	Added the following keywords: WINDOWS_SHORT_NAMES
GETENV	The ENVIRONMENT keyword is now available on all platforms
HELP	Added the following keywords: LEVEL
ICONTOUR	Added the following keywords: BACKGROUND_COLOR, GRID_UNITS, MACRO_NAMES, STYLE_NAME
IDL_Savefile	Introduced
IDLffDicomEx	Introduced
IDLffJPEG2000	Introduced
IDLffLangCat	Introduced
IDLffXMLDOM Classes	Introduced
IDLgrAxis	Added the following properties: ALPHA_CHANNEL
IDLgrBuffer::Select	Added the following keywords: SUB_SELECTION
IDLgrClipboard::Draw	Added the following keywords: CMYK, VECT_SHADING, VECT_SORTING, VECT_TEXT_RENDER_METHOD

Table I-48: Features Introduced in IDL 6.1

Feature	Description
IDLgrContour	Added the following properties: ALPHA_CHANNEL
IDLgrContour	C_COLOR property enhanced to support RGBA color definitions
IDLgrPlot	Added the following properties: ALPHA_CHANNEL
IDLgrPlot	VERT_COLORS property enhanced to support RGBA color definitions
IDLgrPolygon	Added the following properties: ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, SPECULAR
IDLgrPolygon	VERT_COLORS property enhanced to support RGBA color definitions
IDLgrPolyline	Added the following properties: ALPHA_CHANNEL
IDLgrPolyline	VERT_COLORS property enhanced to support RGBA color definitions
IDLgrPrinter::Draw	Added the following keywords: VECT_SORTING, VECT_TEXT_RENDER_METHOD
IDLgrROI	Added the following properties: ALPHA_CHANNEL
IDLgrSurface	Added the following properties: ALPHA_CHANNEL, AMBIENT, DIFFUSE, EMISSION, SHININESS, SPECULAR
IDLgrSurface	VERT_COLORS property enhanced to support RGBA color definitions

Table I-48: Features Introduced in IDL 6.1

Feature	Description
IDLgrSymbol	Added the following properties: ALPHA_CHANNEL
IDLgrVolume	Added the following properties: ALPHA_CHANNEL
IDLgrWindow	Added the following properties: MINIMUM_VIRTUAL_DIMENSIONS, ZOOM_BASE, ZOOM_NSTEP
IDLgrWindow::GetDimensions	Introduced
IDLgrWindow::Select	Added the following keywords: SUB_SELECTION
IDLgrWindow::SetCurrentZoom	Introduced
IDLgrWindow::ZoomIn	Introduced
IDLgrWindow::ZoomOut	Introduced
IDLitComponent	Added the following properties: COMPONENT_VERSION
IDLitComponent::Restore	Introduced
IDLitComponent::UpdateComponentVersion	Introduced
IDLitContainer::FindIdentifiers	Introduced
IDLitDataContainer::Add	Introduced
IDLitIMessaging::ProgressBar	Added the following keywords: CANCEL
IDLitIMessaging::StatusMessage	Added the following keywords: SEGMENT_IDENTIFIER
IDLitManipulator::RegisterCursor	Introduced
IDLitManipulatorManager::GetDefaultManipulator	Introduced
IDLitParameter::GetParameterAttribute	Introduced

Table I-48: Features Introduced in IDL 6.1

Feature	Description
IDLitParameter::QueryParameter	Introduced
IDLitParameter::SetParameterAttribute	Introduced
IDLITSYS_CREATETOOL	Added the following keywords: MACRO_NAMES, STYLE_NAME
IDLitTool::ActivateManipulator	Introduced
IDLitTool::DisableUpdates	Added the following keywords: PREVIOUSLY_DISABLED
IDLitTool::FindIdentifiers	Introduced
IDLitTool::Register	Added the following keywords: DEFAULT
IDLitTool::RegisterCustomization	Introduced
IDLitTool::RegisterFileReader	Added the following keywords: DEFAULT
IDLitTool::RegisterFileWriter	Added the following keywords: DEFAULT
IDLitTool::RegisterOperation	Added the following keywords: ACCELERATOR, DISABLE, DROPLIST_EDIT, DROPLIST_INDEX, DROPLIST_ITEMS, SEPARATOR
IDLitTool::RegisterStatusBarSegment	Introduced
IDLitTool::UnRegisterCustomization	Introduced
IDLitTool::UnRegisterStatusBarSegment	Introduced
IDLitVisualization::BeginManipulation	Introduced
IDLitVisualization::EndManipulation	Introduced
IDLitVisualization::GetRequestedAxesStyle	Introduced
IDLitVisualization::Move	Introduced
IDLitVisualization::On2DRotate	Introduced

Table I-48: Features Introduced in IDL 6.1

Feature	Description
IDLitVisualization::OnAxesRequestChange	Introduced
IDLitVisualization::OnAxesStyleRequestChange	Introduced
IDLitVisualization::OnDimensionChange	Introduced
IDLitVisualization::OnWorldDimensionChange	Introduced
IDLitVisualization::Remove	Added the following keywords: NO_UPDATE
IDLitVisualization::RequestsAxes	Introduced
IDLitVisualization::Restore	Introduced
IDLitVisualization::Rotate	Introduced
IDLitVisualization::SetAxesRequest	Introduced
IDLitVisualization::SetAxesStyleRequest	Introduced
IDLitWindow::DoHitTest	Added the following keywords: ORDER
IDLitWindow::GetSelectedItems	Added the following keywords: ALL
IDLitWindow::OnKeyboard	Added and updated the following arguments: <i>X, Y, Press, Release</i> , and <i>Modifiers</i> added <i>IsAlphaNumeric</i> is now named <i>IsASCII</i> .
IMAGE	Added the following keywords: BACKGROUND_COLOR, GRID_UNITS, MACRO_NAMES, STYLE_NAME
IMAP	Introduced
IPLLOT	Added the following keywords: BACKGROUND_COLOR, MACRO_NAMES, STYLE_NAME

Table I-48: Features Introduced in IDL 6.1

Feature	Description
ISURFACE	Added the following keywords: BACKGROUND_COLOR, MACRO_NAMES, STYLE_NAME
ITGETCURRENT	Added the following keywords: TOOL Note: Routine was renamed IGETCURRENT in IDL 7.1
ITREGISTER	Added the following keywords: ANNOTATION, DEFAULT, FILE_READER, FILE_WRITER, USER_INTERFACE Note: Routine was renamed IREGISTER in IDL 7.1
ITRESOLVE	Introduced Note: Routine was renamed IRESOLVE in IDL 7.1
IVOLUME	Added the following keywords: BACKGROUND_COLOR, EXTENTS_TRANSPARENCY, MACRO_NAMES, STYLE_NAME
LSODE	Added the following keywords: QUIET
MAP_CONTINENTS	Added the following keywords: MAP_STRUCTURE
MAP_GRID	Added the following keywords: MAP_STRUCTURE
MAP_IMAGE	Added the following keywords: MAP_STRUCTURE, MASK
MAP_PROJ_FORWARD	Added the following keywords: FILL
MAP_PROJ_IMAGE	Introduced

Table I-48: Features Introduced in IDL 6.1

Feature	Description
MAX	Added the following keywords: ABSOLUTE
MEDIAN	Added the following keywords: DOUBLE
MIN	Added the following keywords: ABSOLUTE
NORM	Now supports complex data.
ONLINE_HELP	Added the following keywords:: SUPPRESS_PLUGIN_ERRORS
PRODUCT	Added the following keywords: INTEGER, PRESERVE_TYPE
QUERY_JPEG2000	Introduced
QUERY_TIFF	Added the following Info structure fields: DESCRIPTION, DOCUMENT_NAME, DATE_TIME, POSITION Added the following keywords: GEOTIFF
READ_JPEG2000	Introduced
READ_TIFF	Added the following keywords: DOT_RANGE, ICC_PROFILE, PHOTOSHOP
REGION_GROW	Added the following keywords: NAN
RESTORE	Added the following keywords: DESCRIPTION
SAVE	Added the following keywords: DESCRIPTION
SCOPE_LEVEL	Introduced
SCOPE_VARFETCH	Introduced

Table I-48: Features Introduced in IDL 6.1

Feature	Description
SCOPE_VARNAME	Introduced
SIZE	Added the following keywords: FILE_OFFSET, SNAME
SPLINE	Added the following keywords: DOUBLE
SPLINE_P	Added the following keywords: DOUBLE The <i>Xr</i> and <i>Yr</i> arguments now provide support for double-precision arithmetic
TOTAL	Added the following keywords: INTEGER, PRESERVE_TYPE
UNSHARP_MASK	Introduced
WATERSHED	Added the following keywords: LONG, NREGIONS
WIDGET_BASE	Added the following keywords: TAB_MODE
WIDGET_BUTTON	Added the following keywords: ACCELERATOR, TAB_MODE
WIDGET_COMBOBOX	Added the following keywords: IGNORE_ACCELERATORS, TAB_MODE
WIDGET_CONTROL	Added the following keywords: EDITABLE, PROPERTY SHEET_SETSELECTED, TAB_MODE
WIDGET_DRAW	Added the following keywords: IGNORE_ACCELERATORS
WIDGET_DROPLIST	Added the following keywords: TAB_MODE

Table I-48: Features Introduced in IDL 6.1

Feature	Description
WIDGET_INFO	Added the following keywords: PROPERTY SHEET_NSELECTED, PROPERTY SHEET_SELECTED, TAB_MODE
WIDGET_LIST	Added the following keywords: TAB_MODE
WIDGET_PROPERTY SHEET	Added the following keywords: EDITABLE, FRAME, IGNORE_ACCELERATORS, MULTIPLE_PROPERTIES, SUNKEN_FRAME The WIDGET_PROPSHEET_SELECT event structure includes new NSELECTED field and a modified IDENTIFIER field.
WIDGET_SLIDER	Added the following keywords: TAB_MODE
WIDGET_TAB	Added the following keywords: TAB_MODE
WIDGET_TABLE	Added the following keywords: CONTEXT_EVENTS, IGNORE_ACCELERATORS, NO_COLUMN_HEADER, NO_ROW_HEADER, TAB_MODE
WIDGET_TEXT	Added the following keywords: IGNORE_ACCELERATORS, TAB_MODE
WIDGET_TREE	Added the following keywords: TAB_MODE
WRITE_JPEG2000	Introduced

Table I-48: Features Introduced in IDL 6.1

Feature	Description
WRITE_TIFF	Added the following keywords: CMYK, DESCRIPTION, DOCUMENT_NAME, DOT_RANGE, ICC_PROFILE, PHOTOSHOP, XPOSITION, YPOSITION
WV_DWT	Added the following keywords: N_LEVELS

Table I-48: Features Introduced in IDL 6.1

Features Obsolete in IDL 6.1

The following features were present in IDL Version 6.0 but became obsolete in IDL Version 6.1.

Routine	Replaced by	.pro File?
FINDFILE	FILE_SEARCH	
MSG_CAT_CLOSE	IDLffLangCat	
MSG_CAT_COMPILE	IDLffLangCat	
MSG_CAT_OPEN	IDLffLangCat	
IDLffLanguageCat	IDLffLangCat	

Table I-49: Routines Obsolete in IDL 6.1

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
IDLITSYS_CREATETOOL	PANEL_LOCATION keyword	This keyword is no longer honored. Panel location is handled via standard widget layout mechanisms.
IDLitVisualization::Add	GROUP keyword	This keyword was unintentionally and needlessly exposed.
IDLitVisualization::GetCenterRotation	DATA keyword	This keyword is not implemented.
IDLitVisualization::GetProperty	GROUP_PARENT keyword	This keyword was unintentionally and needlessly exposed.
IVOLUME	CUTTING_PLANES keyword	This keyword has been replaced by CLIP_PLANES.

Table I-50: Arguments and Keywords Obsoleted in IDL 6.1

Changes in IDL 6.0

- [Features Added in IDL 6.0](#)
- [Features Obsoleted in IDL 6.0](#)

Features Added in IDL 6.0

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
&&, , ~ logical operators	Introduced
++, -- increment operators	Introduced
##=, #=, *=, +=, -=, /=, <=, >=, AND=, EQ=, GE=, GT=, LE=, LT=, MOD=, NE=, OR=, XOR=, ^= compound assignment operators	Introduced
ARRAY_INDICES	Introduced
CURVEFIT	Added the following keywords: FITA, STATUS
DIALOG_PICKFILE	Added the following keywords: DEFAULT_EXTENSION, OVERWRITE_PROMPT
FILE_BASENAME	Introduced
FILE_DIRNAME	Introduced
FILE_LINES	Added the following keywords: COMPRESS
GAUSSFIT	Added the following keywords: MEASURE_ERRORS
HELP	Added the following keywords: PATH_CACHE
ICONTOUR	Introduced

Table I-51: Features Introduced in IDL 6.0

Feature	Description
IDL_VALIDNAME	Introduced
IDLAnROI::ComputeMask	Added the following keywords: PIXEL_CENTER
IDLgrAxis	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrBuffer	Added the following properties: REGISTER_PROPERTIES
IDLgrClipboard	Added the following properties: REGISTER_PROPERTIES
IDLgrContour	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrImage	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrLight	Added the following properties: REGISTER_PROPERTIES
IDLgrModel	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES

Table I-51: Features Introduced in IDL 6.0

Feature	Description
IDLgrPlot	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrPolygon	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrPolyline	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrPrinter	Added the following properties: REGISTER_PROPERTIES
IDLgrROI	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrROIGroup	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrScene	Added the following properties: REGISTER_PROPERTIES

Table I-51: Features Introduced in IDL 6.0

Feature	Description
IDLgrSurface	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrText	Added the following properties: ALPHA_CHANNEL, DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, FILL_BACKGROUND, FILL_COLOR, KERNING, REGISTER_PROPERTIES
IDLgrView	Added the following properties: REGISTER_PROPERTIES
IDLgrViewgroup	Added the following properties: REGISTER_PROPERTIES
IDLgrVolume	Added the following properties: DEPTH_TEST_DISABLE, DEPTH_TEST_FUNCTION, DEPTH_WRITE_DISABLE, REGISTER_PROPERTIES
IDLgrVRML	Added the following properties: REGISTER_PROPERTIES
IDLgrWindow	Added the following properties: REGISTER_PROPERTIES, VIRTUAL_DIMENSIONS, VISIBLE_LOCATION
IDLitCommand	Introduced
IDLitCommandSet	Introduced
IDLitComponent	Introduced
IDLitContainer	Introduced

Table I-51: Features Introduced in IDL 6.0

Feature	Description
IDLitData	Introduced
IDLitDataContainer	Introduced
IDLitDataOperation	Introduced
IDLitIMessaging	Introduced
IDLitManipulator	Introduced
IDLitManipulatorContainer	Introduced
IDLitManipulatorManager	Introduced
IDLitManipulatorVisual	Introduced
IDLitOperation	Introduced
IDLitParameter	Introduced
IDLitParameterSet	Introduced
IDLitReader	Introduced
IDLITSYS_CREATETOOL	Introduced
IDLitTool	Introduced
IDLitUI	Introduced
IDLitVisualization	Introduced
IDLitWindow	Introduced
IDLitWriter	Introduced
IDLjavaObject	Introduced
IIMAGE	Introduced
INTERVAL_VOLUME	Added the following keywords: PROGRESS_CALLBACK, PROGRESS_METHOD, PROGRESS_OBJECT, PROGRESS_PERCENT, PROGRESS_USERDATA

Table I-51: Features Introduced in IDL 6.0

Feature	Description
IPLOT	Introduced
ISOSURFACE	Added the following keywords: PROGRESS_CALLBACK, PROGRESS_METHOD, PROGRESS_OBJECT, PROGRESS_PERCENT, PROGRESS_USERDATA
ISURFACE	Introduced
ITCURRENT	Introduced Note: Routine was renamed ISETCURRENT in IDL 7.1
ITDELETE	Introduced Note: Routine was renamed IDDELETE in IDL 7.1
ITGETCURRENT	Introduced Note: Routine was renamed IGETCURRENT in IDL 7.1
ITREGISTER	Introduced Note: Routine was renamed IREGISTER in IDL 7.1
ITRESET	Introduced Note: Routine was renamed IRESET in IDL 7.1
IVOLUME	Introduced
LMGR	Added the following keywords: VM
LOGICAL_AND	Introduced
LOGICAL_OR	Introduced
LOGICAL_TRUE	Introduced

Table I-51: Features Introduced in IDL 6.0

Feature	Description
MESH_DECIMATE	Added the following keywords: PROGRESS_CALLBACK, PROGRESS_METHOD, PROGRESS_OBJECT, PROGRESS_PERCENT, PROGRESS_USERDATA
MESSAGE	Added the following keywords: REISSUE_LAST
PATH_CACHE	Introduced
RESOLVE_ALL	Added the following keywords: CLASS
SHMMAP	Added the following keywords: FILENAME, PRIVATE
STRSPLIT	Added the following keywords: COUNT
WIDGET_BUTTON	Added the following keywords: PUSHBUTTON_EVENTS
WIDGET_CONTROL	Added the following keywords: PUSHBUTTON_EVENTS, REFRESH_PROPERTY
WIDGET_INFO	Added the following keywords: COMPONENT, PROPERTY_VALID, PROPERTY_VALUE, PUSHBUTTON_EVENTS,
WIDGET_PROPERTY SHEET	Introduced

Table I-51: Features Introduced in IDL 6.0

Features Obsoleted in IDL 6.0

The following features were present in IDL Version 5.6 but became obsolete in IDL Version 6.0.

Note

For information about routines replaced by the iTools system, see the *iTools User's Guide*.

Routine	Replaced by	.pro File?
LIVE_CONTOUR	ICONTOUR	
LIVE_CONTROL	iTools system	
LIVE_DESTROY	iTools system	
LIVE_EXPORT	iTools system	
LIVE_IMAGE	IIMAGE	
LIVE_INFO	iTools system	
LIVE_LINE	iTools system	
LIVE_LOAD	iTools system	
LIVE_OPLOT	IPLOT	
LIVE_PLOT	IPLOT

LIVE_RECT	iTools system	
LIVE_STYLE	iTools system	
LIVE_SURFACE	ISURFACE	
LIVE_TEXT	iTools system	

Table I-52: Routines Obsoleted in IDL 6.0

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
DIALOG_PICKFILE	GROUP keyword	This keyword was replaced by the DIALOG_PARENT keyword.
EXTRACT_SLICE	CUBIC keyword	EXTRACT_SLICE does not support cubic interpolation.
IDLgrVolume::Init	CUTTING_PLANES keyword	This keyword has been replaced by CLIP_PLANES.

Table I-53: Arguments and Keywords Obsoleted in IDL 6.0

Changes in IDL 5.6

- [Features Added in IDL 5.6](#)
- [Features Obsoleted in IDL 5.6](#)

Features Added in IDL 5.6

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
ATAN	Added the following keywords: PHASE
BESELI, BESELJ, BESELK, BESELY	Added the following keywords: DOUBLE, ITER
BETA	Now accepts complex arguments
COMPILE_OPT	Added the STRICTARRSUBS option
COPY_LUN	Introduced
CURVEFIT	Added the following keywords: YERROR
DIAG_MATRIX	Introduced
DIGITAL_FILTER	Added the following keywords: DOUBLE
ERF	Now accepts complex arguments
ERFCX	Now accepts complex arguments
EXPINT	Added the following keywords: ITER
FILE_COPY	Introduced
FILE_DELETE	Added the following keywords: ALLOW_NONEXISTENT, VERBOSE

Table I-54: Features Introduced in IDL 5.6

Feature	Description
FILE_LINES	Introduced
FILE_LINK	Introduced
FILE_MOVE	Introduced
FILE_READLINK	Introduced
FILE_SAME	Introduced
GAMMA	Now accepts complex arguments
GAUSSFIT	Added the following keywords: CHISQ, SIGMA, YERROR
H5_BROWSER	Introduced
H5_CLOSE	Introduced
H5_GET_LIBVERSION	Introduced
H5_OPEN	Introduced
H5_PARSE	Introduced
H5A_CLOSE	Introduced
H5A_GET_NAME	Introduced
H5A_GET_NUM_ATTRS	Introduced
H5A_GET_SPACE	Introduced
H5A_GET_TYPE	Introduced
H5A_OPEN_IDX	Introduced
H5A_OPEN_NAME	Introduced
H5A_READ	Introduced
H5D_CLOSE	Introduced
H5D_GET_SPACE	Introduced
H5D_GET_STORAGE_SIZE	Introduced
H5D_GET_TYPE	Introduced

Table I-54: Features Introduced in IDL 5.6

Feature	Description
H5D_OPEN	Introduced
H5D_READ	Introduced
H5F_CLOSE	Introduced
H5F_IS_HDF5	Introduced
H5F_OPEN	Introduced
H5G_CLOSE	Introduced
H5G_GET_COMMENT	Introduced
H5G_GET_LINKVAL	Introduced
H5G_GET_MEMBER_NAME	Introduced
H5G_GET_NMEMBERS	Introduced
H5G_GET_OBJINFO	Introduced
H5G_OPEN	Introduced
H5I_GET_TYPE	Introduced
H5R_DEREFERENCE	Introduced
H5R_GET_OBJECT_TYPE	Introduced
H5S_CLOSE	Introduced
H5S_COPY	Introduced
H5S_CREATE_SIMPLE	Introduced
H5S_GET_SELECT_BOUNDS	Introduced
H5S_GET_SELECT_ELEM_NPOINTS	Introduced
H5S_GET_SELECT_ELEM_POINTLIST	Introduced
H5S_GET_SELECT_HYPER_BLOCKLIST	Introduced
H5S_GET_SELECT_HYPER_NBLOCKS	Introduced
H5S_GET_SELECT_NPOINTS	Introduced

Table I-54: Features Introduced in IDL 5.6

Feature	Description
H5S_GET_SIMPLE_EXTENT_DIMS	Introduced
H5S_GET_SIMPLE_EXTENT_NDIMS	Introduced
H5S_GET_SIMPLE_EXTENT_NPOINTS	Introduced
H5S_GET_SIMPLE_EXTENT_TYPE	Introduced
H5S_IS_SIMPLE	Introduced
H5S_OFFSET_SIMPLE	Introduced
H5S_SELECT_ALL	Introduced
H5S_SELECT_ELEMENTS	Introduced
H5S_SELECT_HYPERSLAB	Introduced
H5S_SELECT_NONE	Introduced
H5S_SELECT_VALID	Introduced
H5T_CLOSE	Introduced
H5T_COMMITTED	Introduced
H5T_COPY	Introduced
H5T_EQUAL	Introduced
H5T_GET_ARRAY_DIMS	Introduced
H5T_GET_ARRAY_NDIMS	Introduced
H5T_GET_CLASS	Introduced
H5T_GET_CSET	Introduced
H5T_GET_EBIAS	Introduced
H5T_GET_FIELDS	Introduced
H5T_GET_INPAD	Introduced
H5T_GET_MEMBER_CLASS	Introduced
H5T_GET_MEMBER_NAME	Introduced

H5T_GET_MEMBER_OFFSET	Introduced
H5T_GET_MEMBER_TYPE	Introduced
H5T_GET_NMEMBERS	Introduced
H5T_GET_NORM	Introduced
H5T_GET_OFFSET	Introduced
H5T_GET_ORDER	Introduced
H5T_GET_PAD	Introduced
H5T_GET_PRECISION	Introduced
H5T_GET_SIGN	Introduced
H5T_GET_SIZE	Introduced
H5T_GET_STRPAD	Introduced
H5T_GET_SUPER	Introduced
H5T_IDLTYPE	Introduced
H5T_MEMTYPE	Introduced
H5T_OPEN	Introduced
HELP	Added the following keywords: SHARED_MEMORY
HISTOGRAM	Added the following keywords: LOCATIONS
IBETA	Now accepts complex arguments
IDLanROI::ComputeMask	Added the following keywords: RUN_LENGTH
IDLanROIGroup::ComputeMask	Added the following keywords: RUN_LENGTH
IDLffShape::GetProperty	Added the following keywords: N_RECORDS

Table I-54: Features Introduced in IDL 5.6

Feature	Description
IDLffShape::Init	Added the following keywords: DBF_ONLY
IDLffShape::Open	Added the following keywords: DBF_ONLY
IDLffXMLSAX	Introduced
IDLgrAxis::Init	Added the following keywords: CLIP_PLANES
IDLgrBuffer::GetDeviceInfo	Added the following keywords: MAX_NUM_CLIP_PLANES
IDLgrBuffer::PickData	Added the following keywords: PICK_STATUS
IDLgrClipboard::GetDeviceInfo	Added the following keywords: MAX_NUM_CLIP_PLANES
IDLgrContour::GetLabelInfo	Introduced
IDLgrContour::Init	Added the following keywords: AM_PM, C_LABEL_INTERVAL, C_LABEL_OBJECTS, C_LABEL_NOGAPS, C_LABEL_SHOW C_USE_LABEL_COLOR, C_USE_LABEL_ORIENTATION. CLIP_PLANES, DAYS_OF_WEEK, LABEL_FONT, LABEL_FORMAT, LABEL_FRMTDATA, LABEL_UNITS, MONTHS, USE_TEXT_ALIGNMENTS
IDLgrImage::Init	Added the following keywords: CLIP_PLANES
IDLgrModel::Init	Added the following keywords: CLIP_PLANES
IDLgrPlot::Init	Added the following keywords: CLIP_PLANES

Table I-54: Features Introduced in IDL 5.6

Feature	Description
IDLgrPolygon::Init	Added the following keywords: CLIP_PLANES
IDLgrPolyline::Init	Added the following keywords: CLIP_PLANES, LABEL_NOGAPS, LABEL_OFFSETS, LABEL_OBJECTS, LABEL_POLYLINES, LABEL_USE_VERTEX_COLOR, USE_LABEL_COLOR, USE_LABEL_ORIENTATION, USE_TEXT_ALIGNMENTS
IDLgrROI::Init	Added the following keywords: CLIP_PLANES
IDLgrROIGroup::Init	Added the following keywords: CLIP_PLANES
IDLgrSurface::Init	Added the following keywords: CLIP_PLANES
IDLgrSymbol::Init	Added the following argument: <i>Data</i>
IDLgrTessellator::AddPolygon	Added the following keywords: AUXDATA
IDLgrTessellator::Tessellate	Added the following keywords: AUXDATA
IDLgrText::Init	Added the following keywords: CLIP_PLANES
IDLgrVolume::Init	Added the following keywords: CLIP_PLANES
IDLgrVRML::GetDeviceInfo	Added the following keywords: MAX_NUM_CLIP_PLANES
IDLgrWindow::GetDeviceInfo	Added the following keywords: MAX_NUM_CLIP_PLANES

Table I-54: Features Introduced in IDL 5.6

Feature	Description
IDLgrWindow::PickData	Added the following keywords: PICK_STATUS
IDLgrWindow::SetCurrentCursor	Added the following argument: <i>CursorName</i>
IGAMMA	Now accepts complex arguments
ISOCONTOUR	Added the following keywords: C_LABEL_INTERVAL. C_LABEL_SHOW, OUT_LABEL_OFFSETS, OUT_LABEL_POLYLINES, OUT_LABEL_STRINGS
LA_CHOLDC	Introduced
LA_CHOLMPROVE	Introduced
LA_CHOLSOL	Introduced
LA_DETERM	Introduced
LA_EIGENPROBLEM	Introduced
LA_EIGENQL	Introduced
LA_EIGENVEC	Introduced
LA_ELMHES	Introduced
LA_GM_LINEAR_MODEL	Introduced
LA_HQR	Introduced
LA_INVERT	Introduced
LA_LEAST_SQUARE_EQUALITY	Introduced
LA_LEAST_SQUARES	Introduced
LA_LINEAR_EQUATION	Introduced
LA_LUDC	Introduced
LA_LUMPROVE	Introduced

Table I-54: Features Introduced in IDL 5.6

Feature	Description
LA_LUSOL	Introduced
LA_SVD	Introduced
LA_TRIDC	Introduced
LA_TRIMPROVE	Introduced
LA_TRIQL	Introduced
LA_TRIRED	Introduced
LA_TRISOL	Introduced
LNGAMMA	Now accepts complex arguments
MAKE_DLL	Added the following keywords: REUSE_EXISTING
MAP_PROJ_FORWARD	Introduced
MAP_PROJ_INIT	Introduced
MAP_PROJ_INVERSE	Introduced
MATRIX_POWER	Introduced
MEDIAN	Added the following keywords: DIMENSION
PRODUCT	Introduced
REGISTER_CURSOR	Introduced
SHMDEBUG	Introduced
SHMMAP	Introduced
SHMUNMAP	Introduced
SHMVAR	Introduced
SKIP_LUN	Introduced
SVDFIT	Added the following keywords: SING_VALUES, STATUS, TOL

Table I-54: Features Introduced in IDL 5.6

Feature	Description
SWAP_ENDIAN	Added the following keywords: SWAP_IF_BIG_ENDIAN, SWAP_IF_LITTLE_ENDIAN
SWAP_ENDIAN_INPLACE	Introduced
TRUNCATE_LUN	Introduced
WIDGET_BASE	Added the following keywords: TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TOOLBAR
WIDGET_BUTTON	Added the following keywords: CHECKED_MENU, TOOLTIP
WIDGET_COMBOBOX	Introduced
WIDGET_CONTROL	Added the following keywords: COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DRAW_KEYBOARD_EVENTS, SET_BUTTON, SET_COMBOBOX_SELECT, SET_TAB_CURRENT, SET_TAB_MULTILINE, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP
WIDGET_DRAW	Added the following keywords: KEYBOARD_EVENTS, TOOLTIP

Table I-54: Features Introduced in IDL 5.6

Feature	Description
WIDGET_INFO	Added the following keywords: BUTTON_SET, COMBOBOX_GETTEXT, COMBOBOX_NUMBER, FONTNAME, MAP, SENSITIVE, TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP, TREE_EXPANDED, TREE_ROOT, TREE_SELECT, VISIBLE
WIDGET_LABEL	Added the following keywords: SUNKEN_FRAME
WIDGET_TAB	Introduced
WIDGET_TABLE	Added the following keywords: DISJOINT_SELECTION
WIDGET_TREE	Introduced
WRITE_TIFF	Added the following keywords: COMPRESSION
XROI	Added the following keywords: X_SCROLL_SIZE, Y_SCROLL_SIZE

Table I-54: Features Introduced in IDL 5.6

Features Obsoleted in IDL 5.6

The following features were present in IDL Version 5.5 but became obsolete in IDL Version 5.6.

Routine	Replaced by	.pro File?
HDF_VD_GETNEXT	HDF_VG_GETNEXT	
VAX_FLOAT	VAX_FLOAT keyword to OPENR/OPENU/OPENW	

Table I-55: Routines Obsoleted in IDL 5.6

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
SPAWN	FORCE keyword	This keyword was incorrectly included in the SPAWN documentation.

Table I-56: Arguments and Keywords Obsoleted in IDL 5.6

The following graphics device is obsolete and should not be used in new IDL code.

Graphics Device	Description
The Macintosh Device (MAC)	The MAC device was only available in IDL for Macintosh versions running under OS 9 and earlier. Versions of IDL for Macintosh running under OS X and later use the X device.

Table I-57: Graphics Devices Obsoleted in IDL 5.6

Changes in IDL 5.5

- [Features Added in IDL 5.5](#)
- [Features Obsoleted in IDL 5.5](#)

Features Added in IDL 5.5

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
!CPU System Variable	Introduced
!ERROR_STATE System Variable	Added SYS_CODE_TYPE field
!VERSION System Variable	Added OS_NAME field
!WARN System Variable	Removed TRUNCATED_FILENAME field
ABS , ACOS , ALOG , ALOG10 , ASIN , ATAN , BINDGEN , BYTE , BYTEORDER , BYTSCL , CEIL , CINDGEN , COMPLEX , CONJ , CONVOL , COS , COSH , DCINDGEN , DINDGEN , DOUBLE , EXP , EXPINT , FFT , FINITE , FIX , FLOAT , FLOOR , GAMMA , GAUSSINT , IMAGINARY , INDGEN , INTERPOLATE , ISHFT , L64INDGEN , LINDGEN , LNGAMMA , LONG , LONG64 , MAKE_ARRAY , MATRIX_MULTIPLY , MAX , MIN , POLY_2D , REPLICATE , REPLICATE_INPLACE , ROUND , SIN , SINH , SQRT , TAN , TANH , TOTAL , TVSCL , UINDGEN , UINT , UL64INDGEN , ULINDGEN , ULONG , ULONG64 , VOIGT	Added the following thread pool keywords: TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, TPOOL_NOTHREAD
ACOS , ASIN , ATAN	Now accept complex arguments
ADAPT_HIST_EQUAL	Added the following keywords: FCN

Table I-58: Features Introduced in IDL 5.5

Feature	Description
BINDGEN, BYTARR, BYTE, CINDGEN, COMPLEX, COMPLEXARR, DBLARR, DCINDGEN, DCOMPLEXARR, DINDGEN, DOUBLE, FIX, FLOAT, FLTARR, INDGEN, L64INDGEN, LINDGEN, LONARR, LONG, LONG64, MAKE_ARRAY, OBJARR, PTRARR, RANDOMN, RANDOMU, REBIN, REFORM, REPLICATE, SINDGEN, STRARR, UINDGEN, UINT, UINTARR, UL64INDGEN, ULINDGEN, ULON64ARR, ULONARR, ULONG, ULONG64, WHERE	Modified the D_i argument to specify dimensions as a single array as well as a sequence of scalar values.
BREAKPOINT	Added the following keywords: ON_RECOMPILE
COMPLEX	Added the following keywords: DOUBLE
COND	Added the following keywords: LNORM
CONGRID	Added the following keywords: CENTER
CONVOL	Added the following keywords: MISSING, NAN
CPU	Introduced
CW_FIELD	Added the following keywords: TEXT_FRAME
CW_FSLIDER	Added the following keywords: DOUBLE, SCROLL
CW_PDMENU	Added the following keywords: CONTEXT_MENU
DEFINE_MSGBLK	Introduced
DEFINE_MSGBLK_FROM_FILE	Introduced

Table I-58: Features Introduced in IDL 5.5

Feature	Description
DEVICE	Added the following keywords: LANGUAGE_LEVEL, TRUE_COLOR
ERF	Introduced
ERFC	Introduced
ERFCX	Introduced
FFT	Added the following keywords: DIMENSION
FILE_CHMOD, FILE_DELETE, FILE_MKDIR, FILE_TEST	Added the following keywords: NOEXPAND_PATH
FILE_INFO	Introduced
FILE_SEARCH	Introduced
FINITE	Added the following keywords: SIGN
GAUSSFIT	Added the following keywords: ESTIMATES
GET_DRIVE_LIST	Added the following keywords: COUNT, CDROM, FIXED, REMOTE, REMOVABLE
GETENV	Added argument: <i>Name</i> . The Return Value returns the equivalence string for <i>Name</i> from the environment of the IDL process.
GRID_INPUT	Introduced
GRIDDATA	Introduced
HDF_VD_ATTRFIND	Introduced
HDF_VD_ATTRINFO	Introduced
HDF_VD_ATTRSET	Introduced
HDF_VD_ISATTR	Introduced

Table I-58: Features Introduced in IDL 5.5

Feature	Description
HDF_VD_NATTRS	Introduced
HEAP_FREE	Introduced
HELP	Added the following keywords: DEVICE
HIST_EQUAL	Added the following keywords: FCN
IDLcomIDispatch	Introduced
IDLffMrSID	Introduced
IDLgrBuffer::PickData	Added the following keywords: DIMENSIONS
IDLgrContour::GetProperty	Added the following keywords: DEPTH_OFFSET
IDLgrContour::Init	Added the following keywords: DEPTH_OFFSET
IDLgrContour::SetProperty	Added the following keywords: DEPTH_OFFSET
IDLgrPolygon::GetProperty	Added the following keywords: DEPTH_OFFSET
IDLgrPolygon::Init	Added the following keywords: DEPTH_OFFSET
IDLgrPolygon::SetProperty	Added the following keywords: DEPTH_OFFSET
IDLgrSurface::GetProperty	Added the following keywords: DEPTH_OFFSET
IDLgrSurface::Init	Added the following keywords: DEPTH_OFFSET
IDLgrSurface::SetProperty	Added the following keywords: DEPTH_OFFSET

Table I-58: Features Introduced in IDL 5.5

Feature	Description
IDLgrWindow::PickData	Added the following keywords: DIMENSIONS
INTERVAL_VOLUME	Introduced
MAKE_ARRAY	Added the following keywords: DIMENSION
MAX	Added the following keywords: DIMENSION, SUBSCRIPT_MIN
MESH_OBJ	Added the following keywords: CLOSED
MESSAGE	Added the following keywords: BLOCK, LEVEL, NAME
MIN	Added the following keywords: DIMENSION, SUBSCRIPT_MAX
N_TAGS	Added the following keywords: DATA_LENGTH
NORM	Added the following keywords: LNORM
OPENR/OPENU/OPENW	Added the following keywords: NOEXPAND_PATH
PATH_SEP	Introduced
POLY_AREA	Added the following keywords: DOUBLE
POLYWARP	Added the following keywords: DOUBLE, STATUS
QGRID3	Introduced
QHULL	Introduced
QUERY_MRSID	Introduced

Table I-58: Features Introduced in IDL 5.5

Feature	Description
QUERY_TIFF	Added argument: <i>Info</i>
READ_MRSID	Introduced
READ_TIFF	Added the following keywords: ORIENTATION Now reads 1- and 4-bit TIFF images.
REAL_PART	Introduced
RECON3	Added the following keywords: QUIET
REGION_GROW	Introduced
SETENV	Added argument: <i>Environment_Expression</i>
SHIFT	Modified the S_i argument to specify dimensions as a single array as well as a sequence of scalar values.
SIMPLEX	Introduced
SMOOTH	Added the following keywords: MISSING, NAN
WARP_TRI	Added the following keywords: TPS
WIDGET_ACTIVEX	Introduced
WIDGET_BASE	Added the following keywords: CONTEXT_EVENTS, CONTEXT_MENU
WIDGET_CONTROL	Added the following keywords: CONTEXT_EVENTS
WIDGET_DISPLAYCONTEXTMENU	Introduced
WIDGET_INFO	Added the following keywords: CONTEXT_EVENTS, SYSTEM_COLORS

Table I-58: Features Introduced in IDL 5.5

Feature	Description
WIDGET_LIST	Added the following keywords: CONTEXT_EVENTS
WIDGET_SLIDER	Added the following keywords: SCROLL
WIDGET_TEXT	Added the following keywords: CONTEXT_EVENTS
WRITE_TIFF	Added the following keywords: BITS_PER_SAMPLE, ORIENTATION, UNITS, XRESOL, YRESOL
XOBJVIEW	Added the following keywords: JUST_REG, RENDERER, XOFFSET, YOFFSET
XOBJVIEW_ROTATE	Introduced
XOBJVIEW_WRITE_IMAGE	Introduced
XROI	Added the following keywords: TOOLS

Table I-58: Features Introduced in IDL 5.5

Features Obsoleted in IDL 5.5

The following features were present in IDL Version 5.4 but became obsolete in IDL Version 5.5.

Routine	Replaced by	.pro File?
DELETE_SYMBOL	n/a	
DELLOG	n/a	
DO_APPLE_SCRIPT	n/a	
ERRORF	ERF	
GET_SYMBOL	n/a	

Table I-59: Routines Obsoleted in IDL 5.5

Routine	Replaced by	.pro File?
LJLCT	n/a	
REWIND	n/a	
SET_SYMBOL	n/a	
SETLOG	n/a	
SKIPF	n/a	
TAPRD	n/a	
TAPWRT	n/a	
TRNLOG	n/a	
WEOF	n/a	

Table I-59: Routines Obsoleted in IDL 5.5 (Continued)

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
IDLgrMPEG::Save	CREATOR_TYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
LIVE_PRINT	SETUP keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
OPEN	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
	MACTYPE keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.

Table I-60: Arguments and Keywords Obsoleted in IDL 5.5

Routine	Argument or Keyword	Description
READ_TIFF	ORDER keyword	This keyword was replaced by the ORIENTATION keyword
SPAWN	MACCREATOR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
WIDGET_BASE	APP_MBAR keyword	This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms.
WRITE_TIFF	<i>Order</i> argument	The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead.

Table I-60: Arguments and Keywords Obsolete in IDL 5.5 (Continued)

The following graphics device is obsolete and should not be used in new IDL code.

Graphics Device	Description
The LJ Device (LJ)	The LJ device was only available in IDL for VMS.

Table I-61: Graphics Devices Obsolete in IDL 5.5

Changes in IDL 5.4

- [Features Added in IDL 5.4](#)
- [Features Obsoleted in IDL 5.4](#)

Features Added in IDL 5.4

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
![XYZ].CRANGE	![XYZ].CRANGE, formerly a 2-element vector of single-precision floating point values, is now a 2-element vector of double-precision floating point values.
![XYZ].RANGE	![XYZ].RANGE, formerly a 2-element vector of single-precision floating point values, is now a 2-element vector of double-precision floating point values.
![XYZ].S	![XYZ].S, formerly a 2-element vector of single-precision floating point values, is now a 2-element vector of double-precision floating point values.
![XYZ].TICKFORMAT	The third argument (that is, the argument indicating the value at the tick mark) for any callback functions set via the ![XYZ].TICKFORMAT field will now become a double-precision floating point value (rather than a single-precision floating point value).
![XYZ].TICKINTERVAL	![XYZ].TICKINTERVAL is a scalar indicating the interval between major tick marks for the first axis level. This setting takes precedence over ![XYZ].TICKS .

Table I-62: Features Introduced in IDL 5.4

Feature	Description
![XYZ].TICKLAYOUT	![XYZ].TICKLAYOUT is a scalar that indicates the style to be used to draw each level of the axis.
![XYZ].TICKUNITS	![XYZ].TICKUNITS is a string (or a vector of strings) indicating the units to be used for axis tick labeling.
![XYZ].TICKV	![XYZ].TICKV, formerly a vector of single-precision floating point values, is now a vector of double-precision floating point values.
!MAKE_DLL	Introduced
!P.T	!P.T has changed from a single-precision 4-by-4 array of floating-point values to a double-precision floating-point array of values.
!VERSION	The !VERSION system variable has two new fields called MEMORY_BITS and FILE_OFFSET_BITS that tell you how many bits are used by the current IDL to access memory and files, respectively.
ARRAY_EQUAL	Introduced
ASSOC	Can now read from compressed files.
BESELK	Introduced
BINOMIAL	Added the following keywords: DOUBLE, GAUSSIAN
BLK_CON	Added the following keywords: DOUBLE
BREAK	Introduced

Table I-62: Features Introduced in IDL 5.4

Feature	Description
CALL_EXTERNAL	Added the following keywords: AUTO_GLUE, CC, COMPILE_DIRECTORY, EXTRA_CFLAGS, EXTRA_LFLAGS, IGNORE_EXISTING_GLUE, LD, NOCLEANUP, SHOW_ALL_OUTPUT, VERBOSE
CEIL	Added the following keywords: L64
CLOSE	Added the following keywords: EXIT_STATUS, FORCE
COLORMAP_APPLICABLE	Introduced
CONTINUE	Introduced
CONTOUR	Added the following keywords: CLOSED, NLEVELS, PATH_DOUBLE, PATH_FILENAME, PATH_INFO
CONVERT_COORD	Added the following keywords: DOUBLE
CURVEFIT	Added the following keywords: DOUBLE
CV_COORD	Added the following keywords: DOUBLE
CW_CLR_INDEX	Added the following keywords: VALUE
CW_FILESEL	Added the following keywords: WARN_EXIST
DEVICE	Added the following keywords: PRE_DEPTH, PRE_XSIZE, PRE_YSIZE
DIALOG_PICKFILE	Added the following keywords: FILTER

Table I-62: Features Introduced in IDL 5.4

Feature	Description
DIALOG_READ_IMAGE	Added the following keywords: GET_PATH
DIALOG_WRITE_IMAGE	Added the following keywords: WARN_EXIST
FACTORIAL	Added the following keywords: UL64
FILE_CHMOD	Introduced
FILE_DELETE	Introduced
FILE_EXPAND_PATH	Introduced
FILE_MKDIR	Introduced
FILE_TEST	Introduced
FILE_WHICH	Introduced
FLOOR	Added the following keywords: L64
FREE_LUN	Added the following keywords: EXIT_STATUS, FORCE
FSTAT	The following new fields are returned in the FSTAT structure: <ul style="list-style-type: none"> • ATIME — Date of last access • CTIME — Creation date • MTIME — Date of last modification
GETENV	Added the following keywords: ENVIRONMENT
HANNING	Added the following keywords: DOUBLE
HISTOGRAM	Added the following keywords: BINSIZE, L64, MAX, NBINS, REVERSE_INDICES

Table I-62: Features Introduced in IDL 5.4

Feature	Description
HOUGH	Introduced
IBETA, IGAMMA	Added the following keywords: DOUBLE, EPS, ITER, ITMAX
IDLanROI::GetProperty	Added the following keywords: N_VERTS
IDLanROI::Init	Added the following keywords: DOUBLE
IDLanROI::Rotate	Added the following keywords: CENTER
IDLffShape	Introduced
IDLgrAxis::Init	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS, TICKFORMAT, TICKINTERVAL, TICKLAYOUT, TICKUNITS
IDLgrContour::Init	Added the following keywords: DATA_VALUES, DOUBLE_DATA, DOUBLE_GEOM
IDLgrMPEG::Init	Added the following keywords: BITRATE, IFRAME_GAP, MOTION_VEC_LENGTH, QUALITY
IDLgrPlot::Init	Added the following keywords: DOUBLE
IDLgrPolygon::Init	Added the following keywords: DOUBLE
IDLgrPolyline::Init	Added the following keywords: DOUBLE
IDLgrROI::Init	Added the following keywords: DOUBLE
IDLgrSurface::Init	Added the following keywords: DOUBLE

Table I-62: Features Introduced in IDL 5.4

Feature	Description
IDLgrView::Init	Added the following keywords: DOUBLE
JULDAY	Arguments now accept array values
LABEL_DATE	Added the following keywords: AM_PM, DATE_FORMATS, DAYS_OF_WEEK, OFFSET, ROUND_UP
LAGUERRE	Introduced
LEEFILT	Added the following keywords: DOUBLE
LEGENDRE	Introduced
LINFIT	Added the following keywords: COVAR, MEASURE_ERRORS, YFIT
LIVE_CONTOUR, LIVE_PLOT, LIVE_SURFACE	Added the following keywords: DOUBLE (Note: the LIVE_* Routines were made obsolete in IDL 6.0.)
LMFIT	Added the following keywords: MEASURE_ERRORS, SIGMA
MAKE_DLL	Introduced
MAP_2POINTS	Introduced
MATRIX_MULTIPLY	Introduced
MEMORY	Introduced
MIN_CURVE_SURF	Added the following keywords: CONST, SPHERE
MPEG_OPEN	Added the following keywords: BITRATE, IFRAME_GAP, MOTION_VEC_LENGTH, QUALITY
ONLINE_HELP	Added the following keywords: TOPICS, HTML_HELP

Table I-62: Features Introduced in IDL 5.4

Feature	Description
OPENR/OPENU/OPENW	Added the following keywords: RAWIO, STDIO
POLY_FIT	Added the following keywords: CHISQ, COVAR, MEASURE_ERRORS, SIGMA, STATUS, YERROR, YFIT
RADON	Introduced
RANDOMN, RANDOMU	Added the following keywords: DOUBLE, LONG
READ_JPEG	Added the following keywords: UNIT
READ_PNG	Introduced
READ_PNG	Added the following keywords: ORDER
READ_TIFF	Added the following keywords: CHANNELS, INTERLEAVE
READU	Added the following keywords: TRANSFER_COUNT
REGRESS	Added the following keywords: CHISQ, CONST, CORRELATION, DOUBLE, FTEST, MCOLLATION, MEASURE_ERRORS, SIGMA, STATUS, YFIT
RESOLVE_ROUTINE	Added the following keywords: COMPILE_FULL_FILE
REVERSE	Added the following keywords: OVERWRITE
ROUND	Added the following keywords: L64
SAVGOL	Introduced

Table I-62: Features Introduced in IDL 5.4

Feature	Description
SIZE	Added the following keywords: DIMENSIONS, L64, N_ELEMENTS, STRUCTURE
SOCKET	Introduced
SORT	Added the following keywords: L64
SPAWN	Added the following argument: <i>ErrResult</i> Added the following keywords: EXIT_STATUS, FORCE, HIDE, LOG_OUTPUT, NOSHELL, NOWAIT, NULL_STDIN, STDERR
SPHER_HARM	Introduced
SVDC	Added the following keywords: ITMAX
SVDFIT	Added the following keywords: MEASURE_ERRORS, SIGMA
SWITCH	Introduced
SYSTIME	If the <i>SecondsFlag</i> argument (previously called <i>Arg</i>) is zero, the <i>ElapsedSeconds</i> argument may be set to the number of seconds past 1 January 1970 UTC. Added the following keywords: UTC
The Metafile Display Device	Introduced
TIMEGEN	Introduced
TRIGRID	Added the following keywords: XOUT, YOUT
VALUE_LOCATE	Added the following keywords: L64

Table I-62: Features Introduced in IDL 5.4

Feature	Description
VERT_T3D	Added the following keywords: DOUBLE
WHERE	Added the following keywords: COMPLEMENT, NCOMPLEMENT, L64
WRITE_JPEG	Added the following keywords: UNIT
WRITE_PNG	Added the following keywords: ORDER
XDXF	Introduced
XINTERANIMATE	Added the following keywords: MPEG_BITRATE, MPEG_IFRAME_GAP, MPEG_MOTION_VEC_LENGTH, MPEG_QUALITY
XOBJVIEW	Added the following keywords: BACKGROUND, DOUBLE_VIEW, REFRESH, TLB
XPLOT3D	Introduced
XROI	Introduced
XVOLUME	Introduced

Table I-62: Features Introduced in IDL 5.4

Features Obsoleted in IDL 5.4

The following features were present in IDL Version 5.3 but became obsolete in IDL Version 5.4.

Routine	Replaced by	.pro File?
POLYFITW	POLY_FIT , MEASURE_ERRORS keyword	polyfitw.pro
RIEMANN	RADON	

Table I-63: Routines Obsoleted in IDL 5.4

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
LINFIT	SDEV keyword	This keyword has been replaced by the MEASURE_ERRORS keyword.
LM_FIT	WEIGHTS keyword	This keyword has been replaced by the MEASURE_ERRORS keyword.
OPEN	BINARY keyword	Windows file I/O changed to function like UNIX file I/O.
	NOAUTOMODE keyword	Windows file I/O changed to function like UNIX file I/O.
	NOSDTIO keyword	Keyword was renamed RAWIO.
POLY_FIT	<i>Yfit</i> argument	Argument replaced by the YFIT keyword.
	<i>Yband</i> argument	Argument replaced by the YBAND keyword.
	<i>Sigma</i> argument	Argument replaced by the YERROR keyword.
	<i>Corrm</i> argument	Argument replaced by the COVAR keyword.

Table I-64: Arguments and Keywords Obsolete in IDL 5.4

Routine	Argument or Keyword	Description
REGRESS	<i>Weights</i> argument	Argument replaced by the MEASURE_ERRORS keyword.
	<i>Yfit</i> argument	Argument replaced by the YFIT keyword.
	<i>Const</i> argument	Argument replaced by the CONST keyword.
	<i>Sigma</i> argument	Argument replaced by the SIGMA keyword.
	<i>Ftest</i> argument	Argument replaced by the FTEST keyword.
	<i>R</i> argument	Argument replaced by the CORRELATION keyword.
	<i>Rmul</i> argument	Argument replaced by the MCORRELATION keyword.
	<i>Chisq</i> argument	Argument replaced by the CHISQR keyword.
	<i>Status</i> argument	Argument replaced by the STATUS keyword.
	RELATIVE_WEIGHT keyword	Keyword no longer necessary.
SVDFIT	WEIGHTS keyword	Keyword replaced by the MEASURE_ERRORS keyword.

Table I-64: Arguments and Keywords Obsolete in IDL 5.4 (Continued)

Changes in IDL 5.3

- [Features Added in IDL 5.3](#)
- [Features Obsoleted in IDL 5.3](#)
- [SDF Routines Obsoleted in IDL 5.3](#)

Features Added in IDL 5.3

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
.FULL_RESET_SESSION	Introduced
.RESET_SESSION	Introduced
ADAPT_HIST_EQUAL	Introduced
BINARY_TEMPLATE	Introduced
BREAKPOINT	Added the following keywords: DISABLE, ENABLE
CALL_EXTERNAL	Added the following keywords: UNLOAD
CDF_COMPRESSION	Introduced
CHECK_MATH	Added the following keywords: MASK, NOCLEAR
COMPILE_OPT	Introduced
CW_FILESEL	Introduced
CW_LIGHT_EDITOR	Introduced
CW_LIGHT_EDITOR_GET	Introduced
CW_LIGHT_EDITOR_SET	Introduced
CW_PALETTE_EDITOR	Introduced

Table I-65: Features Introduced in IDL 7.1

Feature	Description
CW_PALETTE_EDITOR_GET	Introduced
CW_PALETTE_EDITOR_SET	Introduced
DIALOG_READ_IMAGE	Introduced
DIALOG_WRITE_IMAGE	Introduced
DILATE	Added the following keywords: BACKGROUND, CONSTRAINED, PRESERVE_TYPE, UINT, ULONG
DLM_LOAD	Introduced
DRAW_ROI	Introduced
ENABLE_SYSRTN	Introduced
EOS_EXISTS	Introduced
EOS_GD_QUERY	Introduced
EOS_PT_QUERY	Introduced
EOS_QUERY	Introduced
EOS_SW_QUERY	Introduced
ERODE	Added the following keywords: PRESERVE_TYPE, UINT, ULONG
EXTRACT_SLICE	Added the following arguments: <i>PlaneNormal</i> , <i>Xvec</i> Added the following keywords: ANISTROPY, VERTICES
FIX	Added the following keywords: PRINT, TYPE
GET_DRIVE_LIST	Introduced
GRID_TPS	Introduced
HDF_SD_SETCOMPRESS	Introduced

Table I-65: Features Introduced in IDL 7.1

Feature	Description
HELP	Added the following keywords: BRIEF, FULL, FUNCTIONS, NAMES, PROCEDURES
IDL_TMPDIR Environment variable	Introduced.
IDLanROI	Introduced
IDLanROIGroup	Introduced
IDLffDICOM::Read	Added the following keywords: ENDIAN
IDLffLanguageCat	Introduced (Note: replaced by IDLffLangCat in IDL 6.1)
IDLgrAxis::Init	Added the following keywords: TEXTALIGNMENTS, TEXTBASELINE, TEXTUPDIR
IDLgrBuffer::GetDeviceInfo	Introduced
IDLgrClipboard::Draw	Added the following keywords: FILENAME, POSTSCRIPT, VECTOR
IDLgrClipboard::GetDeviceInfo	Introduced
IDLgrImage::Init	Added the following keywords: SUB_RECT
IDLgrPrinter::Draw	Added the following keywords: VECTOR
IDLgrROI	Introduced
IDLgrROIGroup	Introduced
IDLgrVRML::GetDeviceInfo	Introduced
IDLgrWindow::GetDeviceInfo	Introduced
IMAGE_STATISTICS	Introduced
INTERPOL	Added the following keywords: LSQUADRATIC, QUADRATIC, SPLINE

Table I-65: Features Introduced in IDL 7.1

Feature	Description
ISOCONTOUR	Introduced
ISOSURFACE	Introduced
LABEL_REGION	Added the following arguments: <i>Data</i> Added the following keywords: ALL_NEIGHBORS, ULONG
LMGR	Added the following keywords: EXPIRE_DATE, INSTALL_NUM, SITE_NOTICE
MESH_CLIP	Introduced
MESH_DECIMATE	Introduced
MESH_ISSOLID	Introduced
MESH_MERGE	Introduced
MESH_NUMTRIANGLES	Introduced
MESH_SMOOTH	Introduced
MESH_SURFACEAREA	Introduced
MESH_VALIDATE	Introduced
MESH_VOLUME	Introduced
MIN_CURVE_SURF	Added the following keywords: DOUBLE
MORPH_CLOSE	Introduced
MORPH_DISTANCE	Introduced
MORPH_GRADIENT	Introduced
MORPH_HITORMISS	Introduced
MORPH_OPEN	Introduced
MORPH_THIN	Introduced

Table I-65: Features Introduced in IDL 7.1

Feature	Description
MORPH_TOPHAT	Introduced
MSG_CAT_CLOSE	Introduced. Replaced by IDLffLangCat in IDL 6.1.
MSG_CAT_COMPILE	Introduced. Replaced by IDLffLangCat in IDL 6.1.
MULTI	Introduced
OPENR/OPENU/OPENW	Added the following keywords: COMPRESS
PARTICLE_TRACE	Introduced
QUERY_IMAGE	Introduced
QUERY_WAV	Introduced
READ_BINARY	Introduced
READ_IMAGE	Introduced
READ_WAV	Introduced
RESOLVE_ROUTINE	Added the following keywords: EITHER, NO_RECOMPILE
ROUTINE_INFO	Added the following keywords: DISABLED, ENABLED, SOURCE
SAVE	Added the following keywords: COMPRESS
SPRSIN	Added the following arguments: <i>Columns, Rows, Values, N</i>
STRCMP	Introduced
STREAMLINE	Introduced
STREGEX	Introduced
STRJOIN	Introduced
STRMATCH	Introduced

Table I-65: Features Introduced in IDL 7.1

Feature	Description
STRMID	Added the following keywords: REVERSE_OFFSET
STRPOS	Added the following keywords: REVERSE_OFFSET, REVERSE_SEARCH
STRSPLIT	Introduced
STRUCT_ASSIGN	Added the following keywords: NOZERO
STRUCT_HIDE	Introduced
TETRA_CLIP	Introduced
TETRA_SURFACE	Introduced
TETRA_VOLUME	Introduced
THIN	Added the following keywords: NEIGHBOR_COUNT, PRUNE
TOTAL	Added the following keywords: CUMULATIVE
VALUE_LOCATE	Introduced
VECTOR_FIELD	Introduced
WATERSHED	Introduced
WRITE_IMAGE	Introduced
WRITE_WAV	Introduced
XOBJVIEW	Introduced

Table I-65: Features Introduced in IDL 7.1

Features Obsoleted in IDL 5.3

The following features were present in IDL Version 5.2 but became obsolete in IDL Version 5.3.

Routine	Replaced by	.pro File?
HDF_DFSD_* Routines	HDF_SD_* Routines	
RSTRPOS	STRPOS , /REVERSE_SEARCH	rstrpos.pro
STR_SEP	STRSPLIT for single character delimiters STRSPLIT , /REGEX for longer delimiters	str_sep.pro

Table I-66: Routines Obsoleted in IDL 5.3

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
BYTEORDER	DTOGFLOAT keyword	This keyword was available only on the VMS platform
	GFLOATTOD keyword	This keyword was available only on the VMS platform.
CALL_EXTERNAL	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	PORTABLE keyword	This keyword was ignored on non-VMS platforms.
	VAX_FLOAT keyword	This keyword was available only on the VMS platform.
DEVICE	DEPTH keyword	This keyword was available only on the VMS platform.
	FONT keyword	This keyword was replaced by the SET_FONT keyword.

Table I-67: Arguments and Keywords Obsoleted in IDL 5.3

Routine	Argument or Keyword	Description
DOC_LIBRARY	FILE keyword	This keyword was ignored on non-VMS platforms.
	PATH keyword	This keyword was ignored on non-VMS platforms.
	OUTPUTS keyword	This keyword was available only on the VMS platform.
LINKIMAGE	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
MAKE_DLL	VAX_FLOAT keyword	This keyword was ignored on non-VMS platforms.
OPEN	<i>Record_Length</i> argument	This argument was ignored on non-VMS platforms.
	BLOCK keyword	This keyword was ignored on non-VMS platforms.
	DEFAULT keyword	This keyword was ignored on non-VMS platforms.
	EXTENDSIZE keyword	This keyword was ignored on non-VMS platforms.
	FIXED keyword	This keyword was ignored on non-VMS platforms.
	FORTRAN keyword	This keyword was ignored on non-VMS platforms.
	INITIALSIZE keyword	This keyword was ignored on non-VMS platforms.

Table I-67: Arguments and Keywords Obsolete in IDL 5.3 (Continued)

Routine	Argument or Keyword	Description
OPEN , <i>continued</i>	KEYED keyword	This keyword was ignored on non-VMS platforms.
	LIST keyword	This keyword was ignored on non-VMS platforms.
	NONE keyword	This keyword was ignored on non-VMS platforms.
	PRINT keyword	This keyword was ignored on non-VMS platforms.
	SEGMENTED keyword	This keyword was ignored on non-VMS platforms.
	SHARED keyword	This keyword was ignored on non-VMS platforms.
	STREAM keyword	This keyword was ignored on non-VMS platforms.
	SUBMIT keyword	This keyword was ignored on non-VMS platforms.
	SUPERSEDE keyword	This keyword was ignored on non-VMS platforms.
	TRUNCATE_ON_CLOSE keyword	This keyword was ignored on non-VMS platforms.
	UDF_BLOCK keyword	This keyword was ignored on non-VMS platforms.
	VARIABLE keyword	This keyword was ignored on non-VMS platforms.
PRINT/PRINTF	REWRITE keyword	This keyword was ignored on non-VMS platforms.

Table I-67: Arguments and Keywords Obsolete in IDL 5.3 (Continued)

Routine	Argument or Keyword	Description
READ/READF	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
READ_TIFF	UNSIGNED keyword	This keyword became obsolete when IDL began supporting an unsigned 16-bit integer data type.
READU	KEY_ID keyword	This keyword was ignored on non-VMS platforms.
	KEY_MATCH keyword	This keyword was ignored on non-VMS platforms.
	KEY_VALUE keyword	This keyword was ignored on non-VMS platforms.
SAVE	XDR keyword	IDL always writes XDR files.
SPAWN	NOCLISYM keyword	This keyword was ignored on non-VMS platforms.
	NOLOGNAM keyword	This keyword was ignored on non-VMS platforms.
	NOTIFY keyword	This keyword was ignored on non-VMS platforms.
WRITEU	REWRITE keyword	This keyword was ignored on non-VMS platforms.

Table I-67: Arguments and Keywords Obsolete in IDL 5.3 (Continued)

SDF Routines Obsolete in IDL 5.3

HDF_DFSD_* routines have been obsolete in IDL 5.3.

What is DFSD and Why Are We Obsoleting It?

DFSD is an SD (Scientific Data Model). DFSD is the older, single-file SD form. The newer SD format, MFSD, is referred to in the IDL API as HDF_SD_*. New IDL code should use HDF_SD_* routines rather than HDF_DFSD_* routines.

Version HDF4.1r2 of HDF has obsoleted the DFSD interface, somewhat forcing us to do so as well. IDL 5.3 uses HDF4.1r3 (Version 4.1, revision 3). It is recommended that users convert their old HDF files to the 4.1r3 format.

The following HDF routines have been obsoleted in IDL 5.3.

- [HDF_DFSD_ADDDATA](#)
- [HDF_DFSD_DIMGET](#)
- [HDF_DFSD_DIMSET](#)
- [HDF_DFSD_ENDSLICE](#)
- [HDF_DFSD_GETDATA](#)
- [HDF_DFSD_GETINFO](#)
- [HDF_DFSD_GETSLICE](#)
- [HDF_DFSD_PUTSLICE](#)
- [HDF_DFSD_READREF](#)
- [HDF_DFSD_SETINFO](#)
- [HDF_DFSD_STARTSLICE](#)

Changes in IDL 5.2

- [Features Added in IDL 5.2](#)
- [Features Obsoleted in IDL 5.2](#)

Features Added in IDL 5.2

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
CALL_EXTERNAL	Added the following keywords: B_VALUE, I_VALUE, L64_VALUE, RETURN_TYPE, UI_VALUE, UL_VALUE, UL64_VALUE
CONSTRAINED_MIN	Added the following keywords: MAXIMIZE
DEVICE	Added the following keywords: GET_DECOMPOSED
DIALOG_PICKFILE	Added the following keywords: MULTIPLE_FILES
EOS_* routines	HDF_EOS support introduced
FINITE	Added the following keywords: INFINITY, NAN
HDF_AN*	HDF_AN interface introduced
HEAP_FREE	Introduced
HDF_GR*	HDF_GR interface introduced
HDF_READ	Introduced
IDL#DICOM	Introduced
IDL#DXF	Introduced

Table I-68: Features Introduced in IDL 5.2

Feature	Description
IDLgrAxis::GetCTM	Added the following keywords: PATH
IDLgrBuffer::GetFontnames	Introduced
IDLgrBuffer::GetTextDimensions	Added the following keywords: PATH
IDLgrBuffer::PickData	Added the following keywords: PATH
IDLgrClipboard::GetFontnames	Introduced
IDLgrClipboard::GetTextDimensions	Added the following keywords: PATH
IDLgrColorbar::ComputeDimensions	Added the following keywords: PATH
IDLgrColorbar::Init	Added the following keywords: PALETTE, THREED
IDLgrContour::GetCTM	Added the following keywords: PATH
IDLgrImage::GetCTM	Added the following keywords: PATH
IDLgrImage::Init	Added the following keywords: INTERPOLATE
IDLgrLegend::ComputeDimensions	Added the following keywords: PATH
IDLgrLight::GetCTM	Added the following keywords: PATH
IDLgrModel::Add	Added the following keywords: ALIAS
IDLgrModel::GetCTM	Added the following keywords: PATH

Table I-68: Features Introduced in IDL 5.2

Feature	Description
IDLgrPlot::GetCTM	Added the following keywords: PATH
IDLgrPolygon::GetCTM	Added the following keywords: PATH
IDLgrPolygon::Init	Added the following keywords: ZERO_OPACITY_SKIP
IDLgrPolyline::GetCTM	Added the following keywords: PATH
IDLgrPrinter::GetFontnames	Introduced
IDLgrPrinter::GetTextDimensions	Added the following keywords: PATH
IDLgrSurface::GetCTM	Added the following keywords: PATH
IDLgrSurface::Init	Added the following keywords: EXTENDED_LOGO, USE_TRIANGLES, ZERO_OPACITY_SKIP
IDLgrTessellator::Tessellate	Added the following keywords: QUIET
IDLgrText::GetCTM	Added the following keywords: PATH
IDLgrVolume::GetCTM	Added the following keywords: PATH
IDLgrVolume::Init	Added the following keywords: DATA2, DATA3, HINTS, VOLUME_SELECT
IDLgrVolume::PickVoxel	Added the following keywords: PATH
IDLgrVRML::GetFontnames	Introduced

Table I-68: Features Introduced in IDL 5.2

Feature	Description
IDLgrVRML::GetTextDimensions	Added the following keywords: PATH
IDLgrWindow::GetFontnames	Introduced
IDLgrWindow::GetTextDimensions	Added the following keywords: PATH
INDGEN	Added the following keywords: BYTE, COMPLEX, DCOMPLEX, DOUBLE, FLOAT, L64, LONG, STRING, TYPE, UINT, UL64, ULONG
L64INDGEN	Introduced
LON64ARR	Introduced
LONG64	Introduced
MAKE_ARRAY	Added the following keywords: L64, UINT, UL64, ULONG
MAP_SET	Added the following keywords: GOODESHOMOLOSINE
MPEG_PUT	Added the following keywords: COLOR
PRINT/PRINTF	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS, STDIO_NON_FINITE
QUERY_JPEG	Introduced
QUERY_PICT	Introduced
QUERY_PNG	Introduced
QUERY_PPM	Introduced
QUERY_SRF	Introduced
QUERY_TIFF	Introduced

Table I-68: Features Introduced in IDL 5.2

Feature	Description
READ/READF	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS
READ_GIF	Introduced
READ_PNG	Introduced
READ_TIFF	Added the following keywords: GEOTIFF, IMAGE_INDEX, SUB_RECT, VERBOSE
READS	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS
STRING	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS
SYSTIME	Added the following keywords: JULIAN, SECONDS
UINDGEN	Introduced
UINT	Introduced
UINTARR	Introduced
UL64INDGEN	Introduced
ULINDGEN	Introduced
ULON64ARR	Introduced
ULONARR	Introduced
ULONG	Introduced
ULONG64	Introduced
WIDGET_* widget creation routines	Added the following keywords: SENSITIVE, UNAME
WIDGET_BUTTON	Added the following keywords: BITMAP

Table I-68: Features Introduced in IDL 5.2

Feature	Description
WIDGET_CONTROL	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS, SET_UNAME
WIDGET_DRAW	Added the following keywords: APP_SCROLL
WIDGET_INFO	Added the following keywords: FIND_BY_UNAME, UNAME
WIDGET_TABLE	Added the following keywords: AM_PM, DAYS_OF_WEEK, MONTHS
WRITE_PNG	Introduced
WRITE_TIFF	Added the following keywords: APPEND, COMPRESSION, FLOAT, GEOTIFF, LONG, SHORT, VERBOSE
XLOADCT	Added the following keywords: UPDATECALLBACK, UPDATECBDATA
XPALETTE	Added the following keywords: UPDATECALLBACK, UPDATECBDATA

Table I-68: Features Introduced in IDL 5.2

Features Obsoleted in IDL 5.2

The following features were present in IDL Version 5.1 but became obsolete in IDL Version 5.2.

Routine	Replaced by	.pro File?
DEMO_MODE	LMGR	demo_mode.pro

Table I-69: Routines Obsoleted in IDL 5.2

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
XMANAGER	MODAL keyword	This keyword was replaced by the MODAL keyword to WIDGET_BASE.

Table I-70: Arguments and Keywords Obsoleted in IDL 5.2

Changes in IDL 5.1

- [Features Added in IDL 5.1](#)
- [Features Obsoleted in IDL 5.1](#)

Features Added in IDL 5.1

The following API features (functions, procedures, object classes or methods, *etc.*) were introduced in this release of IDL.

Feature	Description
ASSOC	Added the following keywords: PACKED
BLAS_AXPY	Introduced
BREAKPOINT	Added the following keywords: CONDITION
BYTEORDER	Added the following keywords: DTOGFLOAT, DTOVAX, FTOVAX, GFLOATTOD, VAXTOD, VAXTOF, SWAP_IF_BIG_ENDIAN (Note: The VMS-only keywords DTOGFLOAT and GFLOATTOD were made obsolete in IDL 5.6.)
CALL_EXTERNAL	Added the following keywords: VAX_FLOAT (Note: This VMS-only keyword was made obsolete in IDL 5.6)
CALL_METHOD	Introduced
COMPUTE_MESH_NORMALS	Introduced
CONSTRAINED_MIN	Introduced
CONTOUR	Added the following keywords: C_CHARTHICK

Table I-71: Features Introduced in IDL 5.1

Feature	Description
DEVICE	Added the following keywords: SET_FONT, GLYPH_CACHE, TTFONT The FONT and USER_FONT keywords were made obsolete, replaced by SET_FONT.
DIALOG_PICKFILE	Added the following keywords: DIRECTORY
EFONT	Added the following keywords: BLOCK
FORMAT_AXIS_VALUES	Introduced
GET_SCREEN_SIZE	Added the following keywords: RESOLUTION
HEAP_FREE	Introduced
HDF_READ	Introduced
HELP	Added the following keywords: DLM, LAST_MESSAGE, MESSAGES
KURTOSIS	Introduced
LIVE_CONTOUR	Introduced (See Features Obsoleted in IDL 6.0)
LIVE_DESTROY	Introduced (See Features Obsoleted in IDL 6.0)
LIVE_EXPORT	Introduced (See Features Obsoleted in IDL 6.0)
LIVE_INFO	Introduced (See Features Obsoleted in IDL 6.0)
LIVE_LINE	Introduced (See Features Obsoleted in IDL 6.0)
LIVE_OPLOT	Introduced (See Features Obsoleted in IDL 6.0)

Table I-71: Features Introduced in IDL 5.1

Feature	Description
LIVE_PRINT	Introduced (See Features Obsoleted in IDL 6.0)
LIVE_RECT	Introduced (See Features Obsoleted in IDL 6.0)

LIVE_TEXT	Introduced (See Features Obsoleted in IDL 6.0)
LMGR	Introduced
LSODE	Introduced
MEAN	Introduced
MEANABSDEV	Introduced
MESSAGE	Added the following keywords: RESET
MPEG_CLOSE	Introduced
MPEG_OPEN	Introduced
MPEG_PUT	Introduced
MPEG_SAVE	Introduced
OPENR/OPENU/OPENW	Added the following keywords: SWAP_ENDIAN, SWAP_IF_BIG_ENDIAN, SWAP_IF_LITTLE_ENDIAN, VAX_FLOAT
PROFILER	Introduced
REPLICATE_INPLACE	Introduced
RESTORE	Added the following keywords: RELAXED_STRUCTURE_ASSIGNMENT, RESTORED_OBJECTS

Table I-71: Features Introduced in IDL 5.1

Feature	Description
SIZE	Added the following keywords: DIMENSIONS, FILE_LUN, N_DIMENSIONS, N_ELEMENTS, STRUCTURE, TNAME, TYPE
SKEWNESS	Introduced
SLICER3	Introduced
SLIDE_IMAGE	Added the following keywords: BLOCK
STDDEV	Introduced
STRMESSAGE	Added the following keywords: BLOCK, CODE, NAME
STRUCT_ASSIGN	Introduced
TVSCL	Added the following keywords: NAN
VARIANCE	Introduced
VAX_FLOAT	Introduced (See Features Obsoleted in IDL 5.6)
WIDGET_CONTROL	Added the following keywords: SET_LIST_SELECT. UPDATE
WIDGET_INFO	Added the following keywords: LIST_MULTIPLE, LIST_SELECT, UPDATE
WIDGET_LIST	Added the following keywords: MULTIPLE

Table I-71: Features Introduced in IDL 5.1

Feature	Description
XBM_EDIT , XDISPLAYFILE , XLOADCT , XMNG_TMPL , XMTOOL , XPALETTE , XSURFACE	Added the following keywords: BLOCK
XINTERANIMATE	Added the following keywords: MPEG_CLOSE, MPEG_FILENAME, MPEG_OPEN

Table I-71: Features Introduced in IDL 5.1

Features Obsoleted in IDL 5.1

The following features were present in IDL Version 5.0 but became obsolete in IDL Version 5.1.

Routine	Replaced by	.pro File?
SLICER	SLICER3	<code> slicer3.pro </code>

Routine	Replaced by	.pro File?
WIDED	n/a	
WIDGET_MESSAGE	DIALOG_MESSAGE	

Table I-74: Routines Obsolete in IDL 5.0 (Continued)

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
MESSAGE	TRACEBACK keyword	This keyword is obsolete and is included for compatibility with existing code only. Traceback information is provided by default.

Table I-75: Arguments and Keywords Obsolete in IDL 5.0

Changes in IDL 4.0 or Earlier

Features not listed as new in previous sections were added to IDL in IDL 4.0 or earlier.

Features Obsoleted in IDL 4.0 or Earlier

The following features became obsolete in IDL version 4.0 or earlier. These features are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `obsolete` subdirectory of the `lib` directory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the `DOC_LIBRARY` routine.

Routine	Replaced by	.pro File?
ADDSYSVAR	DEFSYSV	<code>addsysvar.pro</code>

Table I-76: Routines Obsolete in IDL 4.0 or Earlier (Continued)

The following arguments and keywords are obsolete and should not be used in new IDL code.

Routine	Argument or Keyword	Description
XMANAGER	BACKGROUND keyword	This keyword was replaced by the TIMER keyword to WIDGET_CONTROL.

Table I-77: Arguments and Keywords Obsoleted in IDL 4.0 or Earlier

Obsolete System Variables

The following IDL system variables became obsolete in the change from VAX IDL (IDL version 1) to IDL version 2. While it is highly unlikely that you will find references to these system variables in existing code, we include them here because they are flagged when the OBS_SYSVARS field of the !WARN structure is set equal to one. See [Appendix D, “System Variables”](#) for information on IDL system variables.

System Variable	Replaced by
!BCOLOR	BOTTOM keyword to SURFACE
!COLOR	!P.COLOR
!CXMAX	!X.CRANGE[1]
!CXMIN	!X.CRANGE[0]
!CYMAX	!Y.CRANGE[1]
!CYMIN	!Y.CRANGE[0]
!FANCY	No direct equivalent. Use !P.FONT and !P.CHARSIZE
!FLIP	No equivalent.
!GRID	!P.TICKLEN
!HI	No equivalent.
!IGNORE	!P.NOCLIP
!LINETYPE	!P.LINESTYLE
!LO	No equivalent.
!MTITLE	!P.TITLE
!NOERAS	!P.NOERASE
!NORMALCONT	FOLLOW keyword to CONTOUR
!NSUM	!P.NSUM

Table I-78: Obsolete System Variables

System Variable	Replaced by
!PSYM	!P.PSYM
!SC1	!P.POSITION[0] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[0] * !D.X_VSIZE otherwise.
!SC2	!P.POSITION[2] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[1] * !D.X_VSIZE otherwise.
!SC3	!P.POSITION[1] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[0] * !D.X_VSIZE otherwise.
!SC4	!P.POSITION[3] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[1] * !D.X_VSIZE otherwise.
!TERM	DEVICE procedure.
!TYPE	!X.TYPE, !X.STYLE, !Y.TYPE, !Y.STYLE, !P.TICKLEN
!XMAX	!X.RANGE[1]
!XMIN	!X.RANGE[0]
!XTICKS	!X.TICKS
!XTITLE	!X.TITLE
!YMAX	!Y.RANGE[1]
!YMIN	!Y.RANGE[0]
!YTICKS	!Y.TICKS
!YTITLE	!Y.TITLE
